Nearly two years after the latter match—viz. February 25, 1774—a committee of noblemen and gentlemen met at the *Star and Garter*, in Pall Mall, London, and formally drew up a set of laws for the government of the game, and these are believed to have been the first written laws. They have from time to time undergone extensive alteration and addition. In those days the runs scored were recorded by means of notches made on the edge of a strip of wood; the wickets were placed, as now, 22 yards apart, with a popping-crease, 3 feet 10 inches (now 4 feet) in front of each; the stumps, two in number, were 22 inches long, and the bail 6 inches (a previous wicket having been 2 feet wide, with a hole dug out of the ground in the centre, and 1 foot high); the ball weighed from 5 to 6 ounces. Towards the end of the 18th century a third stump was added to the wicket, which then became 2 inches higher and 1 inch broader, and the only change made since has been a further increase both in height and width. There was at first no limit to the size of the bat, and the early instruments were curved at the end, so that little else than hitting could have been attempted; but as the character of the bowling changed and became more destructive, alterations were made in the instrument of defence, which even at the beginning of the 19th century was inelegant compared with that now used. The later portion of the 18th century was remarkable for the formation of the Marylebone Club, which took place in 1787 on the dissolution of the White Conduit Club, which had had an existence of several years, and had played matches in the fields from which the club took its name. The new club, destined to become the controller of cricket, located itself in Dorset Square, in the parish of Marylebone, for about a quarter of a century; then went to North Bank, Regent's Park, but after a brief period had again to make a move, and finally in 1814 settled down in the St John's Wood Road, its present quarters. 'Lord's,' as the home of the M.C.C. has always been known, is the best-appointed cricket ground in the kingdom.

To John Nyren (born in 1764) and Lambert (born in 1779) we are indebted for the earliest printed instructions as to how to play the game; but these cricketers of vast experience had many imitators, and the comparatively large amount of cricket literature that sprung up at this period furthered the interests of the game in a marked degree. Round-arm bowling was introduced during the lifetimes of these two famous cricketers, and both viewed it with disfavour, Lambert declaring that if continued it would have a degenerating effect. Two counties claimed to have introduced the new style, Kent averring that Wills was the discoverer, and Sussex that the honour rested with Broadbridge. Wills was perhaps the first to really put into practice the style of bowling identical with that now so universally adopted, though the delivery then was not nearly so high as it subsequently became. Round-arm bowling was not allowed to have an uninterrupted career. The delivery increased in height as the advantage of so doing was observed, and so suspiciously like throwing was some of this bowling thought, that after it had been practised for eight or ten years the Marylebone Club discarded it altogether. It was revived, however, about 1825, and on the hard and uneven surfaces upon which cricket was then frequently played, it became so dangerous that recourse was had to leg-guards and batting-gloves, articles which had had no previous existence. During the second quarter of the 19th century the game made rapid strides, and grew in popularity with the middle and upper classes. The celebrated I Zingari, consisting entirely of gentlemen, was

formed in 1845, and cricket began to be taken up by other countries in a slight degree.

County cricket, too, which is at the present time the mainstay of the game, was becoming general, though the interest in many of the matches was discounted by some of the players being found in the ranks of two or three counties in one season. Several of the counties played matches early in the 19th century and even before; but properly organised county clubs did not exist for many years afterwards, as the following dates of formation show: Surrey, 1845; Sussex, 1857 (having been conducted by a committee from 1842); Kent, 1859 (re-formed in 1879); Notts, 1859; Yorkshire, 1863; Lancashire, 1864; Middlesex, 1868; Gloucestershire and Derbyshire, 1870. In June 1873 rules were passed respecting the qualification of county players, and since then county cricket has left little room for the elevens which were wont to perambulate the country under the respective titles of All England, United All England, and later still the United South. Even the matches between the Gentlemen and Players, and North v. South, which at one time were the most attractive of the season, have in a measure had to take a secondary position, for the increased demands of the counties have made it almost impossible for such contests to be of a thoroughly representative character. International cricket dates back as far as 1859, when George Parr took a team out to America. This was followed two years later by the visit of a team to Australia under the captaincy of H. H. Stephenson, and up to 1876 three teams had visited America, and four Australia, while in 1868 England welcomed a party of aborigines. Then 1878 was signalised by the arrival in England of Conway's Australian eleven, the first of its kind, but destined to be followed by many others. Frequent visits between Australian and English cricketers have since then been paid, and on the whole the game has benefited thereby, though some of the ventures have been of a purely commercial character.

So much for its history and the variety of opinions held by its historians. As to the merits of the game as now played but one opinion exists. By general assent cricket stands pre-eminent amongst the many outdoor pastimes pursued during the summer months. All classes play it, and at important matches the company of lookers-on includes representatives of all grades of society. The keenest interest, too, is shown in connection with the leading fixtures of the season, and the results of many matches are telegraphed to all parts of the world. One of the great reasons of the remarkable popularity of this game is its uncertainty. Cricket is not solely an affair of skill; chance is also a factor to a very large extent. Conditions of ground and weather exert such a remarkable influence on the game that in many cases a side which apparently possessed little hope of success has come out of a match victorious. A mistake in the field, an act of carelessness on the part of a batsman, may change the character of the whole game, and indeed 'never lost till won' may with greater reason be applied to cricket than any other pastime. Within the reach of almost every one, cricket is, as a most enthusiastic lover of the game has put it, a health-giving, glorious amusement, calculated to bring out all good qualities, trying alike temper, patience, and courage. To excel at cricket it is necessary that the study of the game should be commenced at an early age, as a great deal of patience and practice is requisite. At nearly all, if not all, of our public schools, a cricket 'coach' or tutor is engaged, and as many of the masters are capable and only too willing to give good advice, the youth of the middle and upper classes have splendid opportunities of cultivating a good style, a most essential element towards success.

Instruction from old cricketers given at practice time is the best of all instruction, and this should always be remembered by those less fortunately placed than public-school boys and university men from whose ranks the best amateur talent is drawn. In speaking of practice, Dr W. G. Grace, the most famous cricketer of this age, says, 'that the more nearly the practice-game approaches to a match, and the more steady and painstaking the player is, the better. One of the best methods of practice I know of is for sixteen people to play amongst themselves; eleven to go into the field two to go to the wickets, two to the umpiring, and one scoring. An afternoon's practice, to last for four hours, will thus give a quarter of an hour in each position to every player, and each player will gain experience in every department of the game, getting half an hour's batting (fifteen minutes at each wicket, no matter how often out), half an hour's bowling (fifteen minutes at each wicket), half an hour's umpiring (fifteen minutes at each end), a quarter of an hour's scoring, and two and a quarter hour's fielding, being fifteen minutes at each place; overs of four balls being bowled, and discipline kept up thoroughly as in a match. . . . The advantage of having eleven in the field when you are practising is that you thereby best learn how to judge the runs, and there is nothing so important to a cricketer as to be able to do this well.'

The game of cricket can be played either at single-wicket or double-wicket, but matches at the former have become very rare. For the latter, two wickets must be pitched opposite and parallel to each other at a distance of 22 yards, each wicket to be 8 inches in width, and to consist of three stumps (of equal and sufficient size to prevent the ball from passing through, 27 inches out of the ground) with two balls (4 inches in length, and when in position not to project more than half an inch above the stumps) upon the top. In a line with the wicket and extending three feet on either side of it, is the bowling-crease, beyond the limits of which the bowler must not go. He uses a ball measuring in circumference not less than 9 inches, nor more than 9½ inches, and weighing not less than 5½ ounces, nor more than 5¾ ounces; and he bowls either round-arm or underhand, and at what pace he pleases. Four feet in front of the wicket and parallel with it is the popping-crease, which defines the batsman's territory. Anywhere behind the popping-crease the batsman is in his own ground. The bat used must not exceed 4½ inches in its widest part and must not be more than 38 inches in length. A match is played between two sides of eleven players each, unless otherwise agreed to; each side has two innings, taken alternately, unless the side which goes in second scores eighty runs (sixty in a one-day match) less than the opposing side, in which case it follows its innings (i.e. has to play again). The choice of innings is decided by lotting. Two members of one side go in to bat, and the rival eleven take up various positions in the field, the ball being bowled in overs from each wicket alternately. The score is reckoned by runs, and a run is obtained each time the batsmen, after a hit, or at any time while the ball is in play, cross and make good their ground from end to end; also by means of a no-ball (the penalty for delivering the ball unfairly or from the wrong position), wide ball (a ball that in the opinion of the umpire is not within reach of the batsman), and in the event of the fieldsman stopping the ball otherwise than with any part of his person. The side which scores the greatest number of runs wins the match. The batsman may be bowled, caught, stumped, or run out; he may be out leg before wicket, for obstructing the field, for hitting the ball twice (except for the pur-

pose of guarding his wicket), or for handling the ball while in play, unless requested to do so by the opposite side. It is the duty of the fieldsmen to save as many runs as possible, and to do this they should not only watch every ball that is bowled, but they should endeavour, if possible, to anticipate

The Cricket Field for Fast Bowling.

where the batsman intends to hit the ball. The positions of the fieldsmen vary with the bowling, but for fast bowling may be given as wicket-keeper, point, cover-point, short-slip, long-slip, third man, long-field, mid-off, mid-on, long-leg, bowler. The bowler as a rule takes slip at the end he bowls from, for the simple reason that little running about is required of him. For point and cover-point great smartness is necessary, and both long-slip and long-leg are places which are not easy to fill satisfactorily; while the long-fields should be good at throwing, and able to judge a catch well. It is necessary to have two umpires and a scorer, and each cricketer should be provided with a bag containing a bat or two, leg-guards, gloves, spiked-sole shoes or boots, and a flannel suit. The best books on the game are *The Cricket Field*; *The English Game of Cricket*; *Cricket: a popular Handbook of the Game*; and *Cricket* in the 'Badminton' series, by Steel, Andrew Lang, Lyttleton, Mitchell, and Grace (1888).

Cricket (*Gryllus*), a familiar genus of insects in the order Orthoptera, near locusts, grasshoppers, &c. A substantial body, a thick head, long feelers, a rasping organ on the wing-covers of the males, wings closely folded lengthwise, but often along with the wing-covers degenerate, great powers of leaping, and a retiring, more or less subterranean habit of life, are some of the more important characteristics of the family (Gryllidae) of which the cricket is a type. The females are fertilised by means of peculiar spermatophores, and as in allied Orthoptera there is no marked metamorphosis in the life-history. In the genus *Gryllus* the head is blunt, the antennæ are long and thin, the wings are always present, the hind-legs are very broad and

strong, and the females have a straight protruding egg-laying organ.—The Field Cricket (*G. campestris*) is very common throughout Europe in fields and meadows (local in England), and is very well known from the sound, by means of which the male captivates his mate. The body is compressed, the head is black and shining, the wing-covers are brown and yellow at the roots. As in other crickets, the noise of the males is made by rubbing the wing-covers against one another. The under side of one of the nervures bears over a hundred sharp transverse ridges or teeth. These insects hide in burrows in the ground, and sometimes do much damage to vegetables. The female lays numerous eggs in the burrow, and the larvæ remain as such through the winter.—The House Cricket (*G. domesticus*) has a lankier, yellowish-brown body an inch long. A recent arrival in the United States, it is common throughout Europe in houses, is said to occur in the open air in Madeira, and even in Britain occasionally wanders out of doors in summer. It hides in nooks and crevices, and loves the neighbourhood of the fire, especially in winter. Its merry note has become associated with ideas of domesticity (as in Dickens's *Cricket on the Hearth*).

House Cricket (*Gryllus domesticus*):
a, full-grown larva; b, pupa; c, perfect insect.

Without the heat of the fire, it becomes more or less dormant in winter. It remains quiet during the day, but hunts about actively at night

Mole Cricket and eggs (*Gryllotalpa vulgaris*).

for crumbs and other scraps both animal and vegetable. For the sake of both food and warmth it often frequents bakehouses. The larvæ are wingless, and the pupæ have only rudimentary wings. The loudest noise made by a cricket is probably that of a Sicilian species (*G. megal-*

cephalus), which is said to make itself heard 'at a distance of a mile.' Closely allied to the above genus is *Myrmecophila*, a wingless cricket with extremely strong hind-legs. Only the females are known, and these live parasitically in ants' nests. The Mole Cricket (*Gryllotalpa*) belongs to the same family, and is distinguished by the enormous burrowing fore-legs, by the large size of the anterior ring of the thorax, and by the absence of an ovipositor in the females. The only European species (*G. vulgaris*) is a large and formidable insect, sometimes attaining a length of two inches. It is of a grayish-brown colour, with a silken sheen. It burrows like a mole in fields and meadows, but is sometimes seen in flight in the evenings. Numerous eggs, inclosed in a cocoon, are laid underground. The larvæ are long in becoming adult. The mole cricket often does damage by biting at the roots of vegetable crops. Like the field cricket, however, it feeds very largely on ground insects and the like. A South American and West Indian species (*G. didactyla*) damages the sugar-canes.

Cricklade, a town in Wiltshire, on the Isis or Thames, 7 miles NNW. of Swindon. Enfranchised under Edward I., it returned two members to parliament till its disfranchisement in 1885, the 'borough' since 1782 having included forty-four parishes and parts of six others, with a pop. (1881) of 51,956. Pop. of town, 1600.

Crieff, a town of Perthshire, on the Earn's left bank, 26 miles NNE. of Stirling, and 18 W. of Perth by two branch lines opened in 1856-66. It is situated in the midst of exquisite scenery, enjoys a pure dry climate, has a large hydropathic (1867), two old market-crosses, some handsome new churches, and Morison's Academy (1859). Its famous cattle fair was transferred about 1770 to Falkirk; the manufacture of woollens was introduced in 1812. Of many seats in the neighbourhood, Drummond Castle (1491), Lord Willoughby de Eresby's, is famous for the beauty of its gardens. Pop. (1851) 3824; (1881) 4469.

Crillon, LOUIS DES BALBES DE BERTON DE, surnamed 'Le Brave,' was born at Murs in Provence in 1541. Under Francis of Lorraine, Duke of Guise, then the model of military chivalry, he was trained for war, and, still a boy, covered himself with glory at the siege of Calais, and at the capture of Guines. His heroism was rewarded with a number of church benefices, which he distinguished to the care of learned clerks. He intrusted himself further at Dreux, Jarnac, and Moncontour. Wounded at Lepanto (1571), he was yet sent to carry the news of the victory to the pope and the French king. His noble heart abhorred the treachery and horrors of St Bartholomew, but he took part in the siege of La Rochelle in 1573. Faithful to his king in his struggle with the Catholic League, after his death he gave hearty allegiance to Henry IV. When the peace with Savoy was concluded, Crillon retired to Avignon, and, after the fashion of a true Catholic warrior, ended his days 'in the exercise of piety and penance,' December 2, 1615. A somewhat melodramatic story is told how once when listening at church to an account of the crucifixion, the old hero, brandishing his sword, cried out: 'Where wert thou, Crillon?'

Crime, in its legal, as opposed to its moral or ethical sense, is an act done in violation of those duties for the breach of which the law has provided that the offender, in addition to repairing, if it be possible, the injury done to the individual, shall make satisfaction to the community. A private wrong, or civil injury, on the other hand, is an infringement on the rights of an individual merely, for which compensation to him is held to be suffi-

cient. Legal criminality is not a permanent characteristic of actions as such, but one decided by considerations of expediency. Without changing its absolute moral character, the same action may, and very often is, criminal in one country or generation, and no crime in another country or generation. It cannot, however, be supposed that the criminality or non-criminality of an action does not exercise an important reflex influence on the moral judgment of the community with respect to the particular action. Malice or evil intention is essential to the character of most crimes, for though there may be an immoral act which it is inexpedient to punish, it can rarely be expedient to punish what is not an immoral act. But it is not necessary that the evil intention shall have had reference to the party injured. If the offender acted in defiance of social duty, a crime has been committed, though not the particular crime intended. For example, it is murder if A kill B by mistake for C, unless the killing of C would have been justifiable, or excusable. But the absurd doctrine of *versans in illicito*, according to which A shooting at his neighbour's poultry, and killing his neighbour, is guilty of murder, is now generally abandoned. The law can take no cognisance of a bare intention which has not ripened into any sort of act. How far Attempts (q.v.) are punishable is always a question of difficulty. The general rule seems to be that if such acts can be unequivocally connected with the criminal intention, they are punishable, though not to the same extent as the completed crime—e.g. if the act is one of a series which, if not interrupted, would result in the commission of the crime, even though the accused voluntarily desisted from further attempts. Pupils under seven years of age, and insane persons, as being incapable of design or intention, are regarded in the eye of the law as incapable of crime; as regards children between seven and fourteen it must be shown that they had capacity to know their act was wrong. In the case of persons under sixteen, otherwise known as juvenile offenders, magistrates have a large discretion to substitute for ordinary punishment confinement in a reformatory school. The legal definition of insanity is well settled in England and Scotland, but is totally inadequate from the medico-psychological point of view. The law of responsibility in *dementia* and *delirium tremens* also requires amendment. Ignorance of law is no defence—e.g. a lordling killing his opponent in a duel in England is guilty of murder. In some cases ignorance of fact is important—e.g. where bigamy is charged against a woman who had reason to believe her husband dead. The defence of *compulsion*, if completely established in fact, is generally sufficient in law. The subjection of a servant to a master, or of a wife or child to a husband or parent, will be no defence, but in the latter case few juries would convict, except in extraordinary circumstances. Magistrates acting *bond fide*, and soldiers and policemen acting under their officers in the ordinary line of duty, are not liable to a criminal charge. Extreme want is no excuse in law, though it furnishes a ground for an application for mercy, as in cannibalism at sea.

In the technical language of the law of England, the term *offence* has a wider signification than crime, the latter including only such of the former as are punishable by Indictment (q.v.). Crimes are divided into *Misdemeanours* (q.v.) and *Felonies* (q.v.), the latter being a higher species of offence than the former. The Criminal and Judicial Statistics give annual data as to the number of trials and convictions, as to police, prisons, and prisoners, the number of the criminal classes (29,226 in England and Wales in 1886), &c. See CRIMINAL LAW.

Crimea (Tartar Krym, anciently the Tauric Chersonese), a peninsula of South Russia, comprising five of the eight districts of the government of Taurida, between the Black Sea and Sea of Azov, joined to the continent of Russia by the Isthmus of Perekop, 18½ miles long by 5½ miles broad at its narrowest part (for a proposed canal across the isthmus, see CANAL). The peninsula is about 200 miles from east to west, by 125 miles from north to south, with about 625 miles of coast-line, and an area of about 10,000 sq. m. In shape it is an irregular quadrilateral, projecting eastwards into the peninsula of Kertch, which terminates at the Strait of Yenikale. Along the Siwash or Putrid Sea on the north, and the Sea of Azov, the coasts are flat and open. To the west of the wide bay of Kaffa or Theodosia the south coast becomes rocky and elevated, and forms a succession of capes and small gulfs. Balaklava, and more especially Sebastopol, have fine harbours.

In the character of its surface, the north, and much the larger part of the Crimea, is only a continuation of the South Russian steppe. The southern part, from Cape Chersonese to the Strait of Yenikale, only about one-fifth of the whole peninsula, is highland, traversed by a mountain-chain, the continuation of the Caucasus—a region geologically, climatically, and botanically distinct from the rest of Russia. The limestone mountains from Cape Chersonese to Baffa Bay show deep erosion, presenting the ruins of a vast tableland, sloping gently northwards into the steppe, but hanging in abrupt precipices southwards. Chatir Dagh or Tent Mount (anciently, Mons Trapezus or Table Mount), the highest summit, 5450 feet, is a quadrilateral mass of over 8 sq. m., elongated southwards, and is isolated on all sides. In the hilly district about Kertch are thermal and naphtha springs, and mud volcanoes. There are some fifty small rivers and rivulets, all fordable except after the melting of the snows and heavy rains. There are about four hundred salt lakes, rich in salt. The climate is healthy, and generally mild. But in winter the steppe is exposed to cold winds, frost, and snowstorms, while the south coast is sheltered and warm. The steppe, though not fertile, yet grazes innumerable herds of cattle, and yields porphyries and various coloured marbles. The northern mountain-slopes are laid out in pastures, thickets, orchards, and gardens watered from the rivers. In the uplands are still magnificent forests of oak, beech, elm, ash, willow, &c. On the southern slopes grow sea-pine; lower down is an Italian vegetation of laurel, pomegranate, fig, arbutus, and vine. Here are famous health-resorts, with Livadia and other imperial residences. Good wine is largely produced, and some exported. Though the Crimea was once famous for its corn, it has suffered much from drought, and much good land is now uncultivated. The fauna is not rich. Of wild quadrupeds are the hare, fox, and small rodents. All the domestic animals of the Russian steppe have been introduced, as also the two-humped camel. The Crimea has a highly prized oyster. The limestone mountains contain porphyry, diorites, and greenstone. Good coal is mined; an extensive field was opened in 1888.

The population numbers about 250,000, of whom 80,000 are Tartars, 130,000 Russians, and 40,000 Greeks, Jews, Bulgarians, Germans, &c. The capital is Simferopol (q.v.), the old Tartar capital being Bakchiserai (q.v.). The Crimea is connected by railway with Russia, the main line running from Alexiejevca to Sebastopol. In the Black Sea, between Europe and Asia, of fine climate and rich in products, the Crimea has from earliest times been a bone of contention for successive nations, and the double or more manifold

names of many places, Greek, Tartar, Turk, Russian, record the dominations they have successively undergone. For the early history of the Crimea, see BOSPORUS. In the 13th century came the Tartars, the last of the Ghirei dynasty abdicating in favour of Russia, 1787. See J. B. Telfer, *The Crimea and Transcaucasia* (1876).

Crimean War. For close upon forty years Britain had been at peace with all the great powers of Europe, but in 1853 a war-cloud arose on the eastern horizon. Russia had long cast a covetous eye upon Constantinople and the Sultan's possessions, and had contrived in various treaties to lay the foundation of a claim to something like a protectorate over the Christians of the Greek Church in Turkey, amounting to three-fourths of the Sultan's subjects in Europe. As early as 1844 the Emperor Nicholas had proposed to divide with Britain the inheritance of the 'sick man,' so he called Turkey; and in 1853 he began to urge his claims in a form which Turkey could not accept without ceasing to remain an independent state. The other great powers intervened as mediators, but in vain; and meanwhile a Russian army took possession of Moldavia and Wallachia. After nearly a year of fruitless diplomacy, negotiations were broken off, and Britain and France agreed to support Turkey by armed intervention. War was proclaimed against Russia on 28th March 1854.

The war thus undertaken lasted two years. At first, England and France stood alone in their support of Turkey; but early in 1855 Sardinia boldly joined the alliance, and sent a contingent to the seat of war. The other powers remained neutral throughout the contest. The chief scenes of operation were the Black Sea and the Baltic. In the spring of 1854 a powerful British and French fleet appeared in the Gulf of Finland; but the Russian fleet declined the combat, and kept safe behind the granite fortresses of Cronstadt and Sveaborg, which, owing to shallow water and difficult navigation, could not be attacked by the large vessels composing the allied fleets. The only thing of importance effected, besides imprisoning the enemy's navy and ruining his commerce, was the destruction of the fortress of Bomarsund, and the capture of the Åland Islands, on which it was situated. The second Baltic campaign, in 1855, was a repetition of the first. Sveaborg was bombarded and partially destroyed, but again the want of gunboats confined the real services of the fleet to a strict blockade of the Russian coasts.

In the Black Sea the Russian fleet followed the same tactics as in the Baltic, and took refuge in the fortified harbour of Sebastopol, sinking vessels across the entrance to keep out the enemy. On land, the Turkish forces, under Omar Pasha, had sustained during the winter of 1853-54 an heroic contest on the Danube against the Russian invaders. The French and British troops sent to the aid of the Sultan were landed at first in European Turkey, chiefly at Varna (April and May 1854). But the valiant defence of Silistria by the Turks themselves rendered our advance in that direction unnecessary; after using every effort for six weeks, the Russians had to retire baffled from before the place. The allies having suffered great loss from cholera at Varna, it was resolved to carry the war into the Crimea; and on 14th September an army of 25,000 British under Lord Raglan, as many French under Marshal St Arnaud, and 8000 Turks, landed on the west coast, 30 miles north of Sebastopol. On the 20th they attacked and completely defeated a Russian army strongly posted on the steep heights above the river Alma; then taking up position near Balaklava, to the south of Sebastopol, they commenced the siege of that vast fortress. The Russians made repeated attempts,

with overwhelming masses of troops, to force the allied position, which led to the sanguinary battles of Balaklava (25th October) and Inkermann (5th November).

Balaklava was mainly a cavalry action, and did far more credit to our soldiers' gallantry than to their commanders' generalship. It will ever be memorable for the glorious charge of the Light Brigade, who, in obedience to a bungled order, rode a mile and a half beneath a murderous fire against the Russian army in position. Faster and faster grew the pace, until with a cheer that was many a hero's death-cry, they broke right into the battery, sabred the gunners, and burst through a column of infantry. Then they paused, and cut their way back; but out of the six hundred who had ridden forth, not two hundred returned. 'It is magnificent, but it is not war,' was the comment of a French general. Inkermann, known as the Soldiers' Battle, was fought on a dark and drizzly morning of autumn. Taken unawares, and short of cartridges, 8000 British sustained for several hours a hand-to-hand fight against six times that number of Russians, till 6000 French came to their aid, and completed the rout of the enemy.

Throughout the ensuing winter, the allies, especially the British, suffered terrible hardships, owing partly to the rigour of the climate, but more to the shameful breakdown of the system for provisioning the army. The supplies of food, clothing, and other necessities were often sent where they were not wanted. The hospitals, too, were frightfully mismanaged; barely 12 per cent. of our total loss in the war (20,656) dying in battle, the rest in hospital. To Florence Nightingale, a lady of gentle birth, was due the establishment of proper nursing in the military hospitals, not merely then, but thereafter.

The prodigious extent and strength of the fortifications of Sebastopol (q.v.), together with the skill and obstinacy of its defence, protracted the siege for nearly a twelvemonth, and rendered it well-nigh the greatest in history. In March 1855 died the Czar Nicholas, whose ambition was the cause of the contest; but under his son and successor, Alexander II., Russia continued to sustain the enormous drain on her population and resources. The trenches, or lines of attack, had drawn closer and closer to the Russian works, till at one point the foes were well within speaking distance; at last, on 8th September 1855, after a three days' tremendous cannonade by the allies, the French stormed and carried the Malakoff fort, the key of Sebastopol. That night the Russians evacuated the city, or rather its blazing ruins. Except for the surrender of Kars in Circassia, after its gallant defence by the Turks under Colonel Williams, a British officer, the war ended with the fall of Sebastopol. In March 1856 a treaty of peace was signed at Paris, by which Russia lost all she had gained or attempted to gain; but the article prohibiting Russia from building arsenals or having war-ships on the Black Sea (q.v.) was abrogated in 1871. See Kinglake's *Invasion of the Crimea* (8 vols. 1863-87).

Criminal Conversation (usually CRIM. CON.). See ADULTERY.

Criminal Law is that branch of law which deals with crimes and their punishment. The right to visit with penal consequences actions which threaten the order of society, is exercised in one shape or another wherever human society exists. The earliest form of penal law seems to have rested on a principle of private vengeance, and to have taken shape in the *lex talionis*, the law of retaliation formulated in the familiar passage in Exodus which lays down as a fit punishment an eye for an eye and a tooth for a tooth. The severity of this

doctrine was mitigated when the right of personal vengeance was satisfied by a money payment, a custom which can be traced in the early laws of the Hebrews, Greeks, and Romans, and which is particularly characteristic of early Teutonic systems of penal law. According to these a family is made pecuniarily responsible for the offences of its members, or accepts a fine as a compensation for the life of a lost kinsman (see WEREGILD). When a man was killed, a part of this fine was paid to the king or head of the community to compensate the clan's loss of a fighting member; and in the distinction established between injuries done to the individual and injuries done to the community, the foundation of a system of criminal law was laid. The sovereign power in a community or state took up the wrongs of private persons, and exercised a right of public vengeance. Legislation upon this principle had for its object the intimidation of the wrong-doer, and was specially characterised by the great variety and severity of its punishments. It was not until the 18th century that a more enlightened jurisprudence prevailed. Beccaria's work, *On Crimes and Punishments*, published in 1766, has exercised a strong influence on the criminal legislation of Europe by urging the claims of criminals to humane consideration, and examining the basis in morals upon which criminal law rests. The principle which Beccaria opposed to the older theory of public vengeance was that of a legitimate defence restrained within the limit of the common interest. The true object of criminal law was set down as the amendment of the criminal, and the restoration to him of the rights of a free man. From this point of view many jurists have opposed Capital Punishment (q.v.), and some go so far as to oppose all forms of corporal punishment on the ground that they degrade the criminal. The modern view gains ground that crime is to be looked upon as a disease of the social body, and that the remedy is to be looked for rather in improved education and social well-being than in a repressive system of arbitrary punishments. The criminal law of a particular state is the body of legal rules affecting the commission and prosecution of crimes. See CRIME, and the several articles on MURDER, THEFT, PERJURY, &c., also JUDGE, WITNESS, &c.; and for the criminal courts, see COMMON LAW (COURTS OF), ASSIZE, HIGH COURT OF JUSTICE, JUSTICIARY, JURY-TRIAL, JUSTICE OF PEACE, QUARTER SESSIONS.

The procedure in criminal cases differs in England and Scotland. In England the prosecution is at the instance of the private person injured, and the trial resembles an ordinary civil litigation to a greater degree than is usual in other countries. The proceedings begin before justices by an 'information,' upon which the justices issue a summons directed to the party charged, or grant a warrant for apprehending him. When the person charged appears, the witnesses for the prosecution are examined in his presence, and he is at liberty to put questions to them, either personally or by counsel. After the examination the accused may say anything he desires in answer to the charge, but what he says is taken down, and may be given in evidence against him at his trial. After the statement of the accused, he may call witnesses, and the justices are bound to take the statement of these. Thereafter the justices may, according to their opinion of the evidence, either discharge the accused, or commit him to gaol, or admit him to bail. The commitment is for trial, either at quarter sessions or at the assizes. The first step in the trial is the presentment of an indictment to the grand-jury, who are chosen from gentlemen of standing in the district. The grand-jury having been charged by the judge, and having heard the

witnesses, find a 'true bill' if they are satisfied that there is a *prima facie* case. The case then goes to trial in open court before a judge and jury. The prisoner is entitled to be represented by counsel, although there is no provision of law in England, as in Scotland, to find counsel for prisoners who cannot afford the customary fee. The order of proceeding at trial is as follows: When a jury has been sworn, and the defendant has pleaded not guilty, the counsel for the prosecution opens the case, and then examines the witnesses for the prosecution, who are afterwards cross-examined and re-examined according to the rules of evidence. Counsel for the prisoner then states the defence, and examines witnesses, and may sum up the evidence to the jury if there are no witnesses for the defence; counsel for the prosecution sums up the evidence against the prisoner. When evidence is given for the prisoner, the counsel for the prosecution has the right to reply; but in practice it is hardly ever exercised. After the reply, the judge sums up the case, and the jury consider their verdict, which must be unanimous. If the verdict be not guilty, the prisoner is discharged; if guilty, he is sentenced. The prisoner has a right to be present throughout the trial, though the court may probably proceed in his absence if he so misconducts himself as to make it impossible to try him with decency. See Sir J. F. Stephen's *Digest of the Law of Criminal Procedure* (1883), and his *History of that law* (1883).

The procedure in Scotland has been altered and simplified by the Criminal Procedure (Scotland) Act, 1887. The first step is a petition for warrant to arrest and commit, which may be granted by any magistrate. A person arrested is entitled at once to have intimation sent to any law-agent he may name that his services are required; and to have a private interview with his legal adviser before the examination, and the legal adviser may be present at the examination. The declaration of the accused is then taken by the magistrate, whose duty it is to warn him that the declaration may be used against him. The next step is the precognition or inquiry into the facts of the crime, which is conducted as a rule by the procurator-fiscal. The accused is then committed for trial on a warrant specifying the offence charged. He is then served with an indictment. Where the trial is by jury, all public prosecution is conducted on indictment in name of the Lord Advocate. The old form of indictment was a lengthy and cumbersome document, and the strictness of the rules as to its form laid it often easily open to technical objections. A simpler and shorter form was introduced by the Criminal Procedure Act. On the day fixed, the trial proceeds in the presence of the prosecutor, who may appear by deputy, and that of the prisoner, which is indispensable. The panel is first called on to state objections to the relevancy of the libel; these being disposed of, to plead. If he pleads not guilty he is remitted to the knowledge of an assize—i.e. his case is laid before a jury of fifteen. Evidence is led, first for the prosecution, and then for the defence, and counsel for the parties address the jury, the accused's counsel having the last word. The presiding judge then sums up the evidence, and directs the jury in law. The jury then return their verdict, which need not be unanimous, if a majority agree. If the verdict be not guilty, or *not proven*, the accused is dismissed from the bar. If it be guilty, the prosecutor moves the court for sentence, which is pronounced; and can only be reviewed by way of pardon. See Macdonald's *Criminal Law of Scotland* (1877) and N. Macdonald's *Manual of the Criminal Procedure (Scotland) Act* (1887).

The criminal law of the United States has closely

followed that of England; as, for example, in the important principle of the law of England (differing from that of most countries) that the accused person is not compelled to testify. But in the United States there are public prosecutors—the district-attorneys—one of whom is appointed by the president in each judicial district. In some states there may also be private prosecution.

Crimp. A crimp is a person who usually keeps a sailors' boarding-house, and who professedly occupies himself in finding employment for seamen. There is no need for such an agent anywhere in the United Kingdom, as every seaman seeking employment can go for that purpose to the Mercantile Marine Offices, where crews are engaged under the supervision of the officers of the Board of Trade, or he can go direct to any ship in need of hands. Crimps, or 'runners' as they are often called, and the disreputable persons who are associated with them, live by pandering to the follies and vices of the lower and less provident class of seamen. On the arrival of a ship in port, their object is to get hold of the sailor and his effects, keep him by the demoralising agency of drink or drugs in their power until his wages are paid; fleece him of his money, and even of his clothes; and, after he is no longer profitable to them, get him reshipped. They will therefore make him a small advance to refit him, recompensing themselves out of the advance of wages which, in one form or another, many seamen get on joining a ship.

Strong efforts have been made by legislation in Great Britain in recent years to put down this evil, chiefly by banking seamen's wages at the Mercantile Marine Offices, or transmitting them through the same offices to the seaman's wife and family free of charge, or promptly sending the seaman himself off by rail to his home, and sending his wages after him, by the Board of Trade officials. The erection of sailors' homes has also been very beneficial.

Certain ports abroad, notably Shanghai, Callao, San Francisco, New York, and New Orleans, have acquired in the past a most evil notoriety for the worst brutalities in connection with crimping; and even now it is said that the crimps in many ports abroad have so much political power that the authorities do not dare to put them down, and that they work more or less in corrupt concert with the port authorities and the magistrates.

Crimson. See RED, DYEING.

Crinan Canal, an artificial waterway, 9 miles long, in the west of Argyllshire, between Loch Gilp, a branch of Loch Fyne, and Loch Crinan, in the Sound of Jura, at the head of the peninsula of Kintyre. Constructed in 1793–1801 at a cost of £183,000, to avoid the circuitous passage of 70 miles round the Mull of Kintyre, it is 24 feet broad and 10 deep, has 15 locks, and admits vessels of 200 tons. In 1859 the three reservoirs feeding it burst, and government had to repair the damage at a cost of £12,000. The receipts seldom cover the year's expenditure.

Crinoidea (Gr., 'lily-like'), a class of Echinodermata, sometimes called feather-stars or sea-lilies, and well known in fossil form as encrinites or stone-lilies. While agreeing in general structure with starfishes and other Echinoderms, the Crinoids present many peculiarities. They are fixed permanently or temporarily, mouth upwards, by a stalk, which is usually jointed. The visceral mass is inclosed in a cup at the apex of the stalk. As in most other Echinoderms, there are numerous limy plates, forming the stalk, the supporting cup, the framework of the arms, &c. The anus lies near the mouth. The 'arms,' though typically five in number, may be very much multiplied (towards

200) by branching; they usually bear lateral pinules, which produce a feathered appearance. The water-vascular ring does not communicate directly

Fig. 1.—Pentacrinus.

a central mass and radial extensions, being both sensory and motor. The sexes are separate and similar. The ciliated larval form (known in the case of Antedon) is not as divergent as that of the other classes of Echinoderms.

Mode of Life.—The Crinoids are typically stalked and more or less fixed, but the modern family of Comatulidae break off from their stem at a certain stage. The stem of the stalked forms is usually anchored to a rock or other foreign object, but in some cases the animal grows more loosely on a muddy bottom. Like the extinct forms, the modern stalked Crinoids grow in masses, forming beds of sea-lilies on the ocean floor. Over a hundred specimens have been dredged in a single haul. When they move about, as in the Comatulidae, they do so by alternately bending and straightening the arms. The food, which consists of minute organisms (protozoa, diatoms, small crustacea, &c.), is wafted down ciliated grooves on the pinules and arms to the mouth. The known larvae are actively free-swimming by means of cilia. Comatula and some others are the hosts of curious parasitic Chaetopod worms (Myzostomidae), which cause deformities on the arms. Like many other Echinoderms, the Crinoids have the power of regenerating lost parts. Broken-off arms may be replaced, and even the renewal of the visceral mass has been observed.

Fig. 2.

A, free-swimming larva, with skeleton of adult forming inside; B, fixed stalked young (Pentacrinus-like) stage.

swimming by means of cilia. Comatula and some others are the hosts of curious parasitic Chaetopod worms (Myzostomidae), which cause deformities on the arms. Like many other Echinoderms, the Crinoids have the power of regenerating lost parts. Broken-off arms may be replaced, and even the renewal of the visceral mass has been observed.

Important Forms and Classification.—The best-known genus is the cosmopolitan Antedon or Comatula, of which *A. rosacea* is the most abundant

species, frequently dredged off British coasts. Along with the large genus Actinometra and some others less important, Antedon represents the family of Comatulids, which differ from other Crinoids in being stalked only in their youth. Professor J. Vaughan Thompson has the credit of having discovered the young stalked stage of *A. rosacea*, and thus revealing the existence of a most interesting habit. The free Antedon swims gracefully by bending its ten arms, and then settles down again for

Fig. 3.—Free Adult showing wreath of anchoring hooks.

a while, anchoring itself by means of an inferior wreath of clawed attaching processes. Among permanently stalked Crinoids may be mentioned the genus *Pentacrinus* (e.g. *P. asterius*), from the Atlantic and Pacific, often at great depths; *Rhizocrinus* (e.g. *R. lofotensis*), from the Atlantic, usually abyssal; *Holopus*, from the Caribbean Sea, with very massive arms, and only a single extant species. These and others, being of more recent origin, are distinguished as Neocrinoidea, from the wholly extinct Palaeozoic forms, the Palaeocrinoidea or Tesselata. In the latter the cup does not invariably show that fivefold symmetry which is constant in the former.

Distribution.—Though recent deep-sea explorations have greatly increased the catalogue of living forms to a total of over 400 species, distributed in twelve genera, these nevertheless represent but a small fraction of the extinct Crinoid fauna. Over 200 genera and 1500 species are known from fossiliferous strata. These begin to appear in the Cambrian, and attain maximum development in Silurian, Devonian, and Carboniferous times. Recent Crinoids never attain the size exhibited by some of the fossil forms. Extinct species have been found with stems 50 and 70 feet in length.

Many of the stalked Crinoids are found at great depths, and some of the Challenger dredgings revealed the persistence in the deep sea of types which had previously been regarded as extinct. Thus the pear-encrinites (Apicrinidae) are continued in the abyssal genera *Rhizocrinus*, *Bathycrinus*, and *Hyocrinus*. *Bathycrinus gracilis* has been dredged from a depth of 2435 fathoms, an Antedon from 2900 fathoms, *Holopus* and *Hyocrinus* from 1200 to 2500 fathoms. The majority, however, and especially the free forms, frequent shallower water. Antedon is a cosmopolitan genus; *Holopus* is confined to the Caribbean Sea; stalked Crinoids are found between the parallels of 68° N. and 46° S. lat.; Comatulidae between 81° N. and 52° S. lat.

Relations.—There seems little doubt that the Crinoids, Ophiuroids, and Asterooids are more closely linked to one another than to Echinoids and Holothurians. In some ways the Crinoid type is struc-

turally the lowest, and probably appeared first. With the primitive Crinoids two entirely extinct classes must be associated—the Cystoids and Blastoids. The former were sessile or shortly stalked, with oval or globular bodies, and very limy. The Blastoids had a short stalk and ovate body, and were also heavily weighted with lime.

See ECHINODERMATA, STANFISH, &c.; P. H. Carpenter, *Challenger Reports*, xi. (1884), &c.; De Loriol, *Palaeontologie Française* (Paris, x. 1882-84); H. Ludwig, *Anat. der Crinoiden* (Leip. 1877); E. Perrier, *La Comatula rosacea* (Archiv. Zool. Exper., ii. 1872); C. Wachsmuth and F. Springer, *Revision of Palaeocrinoiden* (Phila. 1879-85); Zittel, *Handbuch der Paläontologie* (1876-80).

Crinoline, the name originally given by the French *modistes* to a fabric of horse-hair (Fr. *crin*, 'hair'), capable of great stiffness, and employed to distend women's attire. It was applied in a general way to those structures of steel wire or hoops, by means of which women between 1855 and 1866 attained enormous dimensions—12, even 15 feet in circumference. Such fashion of expansion was not new. There was the *farthingale* of Queen Elizabeth, when the upper part of the body was encased in a cuirass of whalebone, which was united at the waist with the equally stiff farthingale of the same material, descending to the feet in the form of a great drum. We next hear in 1711 of 'that startling novelty the hoop-petticoat,' which differed from the farthingale in being gathered at the waist; and by 1744 hoops had grown so extravagant, that a woman occupied the space of six men. An elongated oval form also came into fashion, raised at each side to show the high-heeled shoes, causing caricaturists to say that a lady looked like a donkey carrying its panniers. These hoops were of whalebone, with canvas over them, having capacious receptacles on each side for articles of convenience. In 1780 we find hoops of cane used, being advertised to 'outwear the best sort of whalebone.' About 1796 hoops had been discarded in private life, but were still the mode at court, and never had been seen in more full-blown enormity, continuing so to the time of George IV., when they were abolished by royal command. The *crinolette* was the name given to a small crinoline causing the dress to project behind only, and so akin to the bustle and dress-improver.

Crinum, a genus of bulbous-rooted amaryllids (sometimes included under *Sternbergia*), chiefly tropical, and frequently cultivated in hothouses—e.g. *C. amabile* of India, *C. scabrum* of Brazil, &c. *C. capense* of South Africa is a fine hardy species, with large, fragrant, rosy white flowers, remarkable for the depth and slenderness of their tube. The bulbs of *C. asiaticum* are powerfully emetic, and are used in some parts of the East in cases of poisoning.

Cris-cross Row. See HOBBYBOOK.

Crispin, saint and martyr, about the middle of the 3d century, under the reign of Diocletian, fled, along with his brother Crispian, from Rome into Gaul, where he worked as a shoemaker in the town which is now called Soissons, and distinguished himself by his exertions for the spread of Christianity, as well as by his works of charity. According to the legend, his benevolence was so great that he even stole leather to make shoes for the poor! From this, charities done at the expense of others have been called *Crispinades*. In the year 287 he and his brother suffered martyrdom by being thrown into a caldron of boiling lead. Both are commemorated on the 25th October. Crispin is the universally recognised patron saint of shoemakers.

Cristofori, or CRISTOFALI, BARTOLOMMEO, harpsichord-maker, was born at Padua in 1653, and

died at Florence in 1731. He is regarded as the inventor of the pianoforte.

Critchett, GEORGE, ophthalmic surgeon, born in London in 1817, became F.R.C.S. in 1844, and was assistant-surgeon and (1861-63) surgeon to the London Hospital. He early devoted his attention to ophthalmology, and was attached to the hospital at Moorfields from 1846; in 1854 he published a course of lectures on *Diseases of the Eye*, and from 1876 he was ophthalmic surgeon and lecturer at the Middlesex Hospital, where his operations acquired a European fame. He died 1st November 1882.

Critias, one of the pupils of Socrates, but unfortunately one who was rather a hearer than a doer of his word. On his return to Athens from banishment, he put himself at the head of the oligarchical party, and was afterwards the most rapacious and cruel among the thirty tyrants set up by the Spartans (404 B.C.). In the same year he fell at Munychia, resisting Thrasybulus and the exiles. Critias had a high reputation as an orator, and besides wrote poetry.

Critical Temperature is that temperature below which a substance may, and above which it cannot, be liquefied *by pressure alone*. This temperature for carbonic acid gas, for example, is 30.9° C.—i.e. below that temperature, the liquefaction of the substance may be easily effected if sufficient pressure be applied; but above it the substance cannot be liquefied, no matter how great be the pressure to which it is subjected. The discovery of the critical temperature by Dr Andrews in 1869 first gave the means of distinguishing between a true gas and a true vapour; for the former is a substance above, the latter one below, its critical temperature. When any substance is at this temperature it is in the critical state—i.e. its passage from liquid to gas, or *vice versa*, is one in which the two parts, liquid and gaseous, so merge into one another as to render them optically indistinguishable. The critical temperatures of oxygen, hydrogen, and nitrogen (formerly termed 'permanent' gases) are all extremely low, and hence liquefaction can only be effected (as it has already been) by the application of intense cold as well as considerable pressure. On the other hand, such vaporous bodies as sulphurous anhydride, alcohol vapour, ether vapour, &c. can, provided the pressure be sufficiently great, be liquefied at ordinary air temperatures, since these are much below their critical temperatures. See GAS, VAPOUR, STATES OF MATTER.

Croaghpatrick, a celebrated Irish mountain where St Patrick is said to have begun his missionary work. It stands about 4 miles SW. of Westport, in the south of County Mayo, and is 2510 feet high.

Croatia and Slavonia (Hung. *Horvát-Szlavonország*) form, together with their former 'Military Frontier,' a crown-land belonging to the Hungarian section of Austria (q.v.), lying between the Adriatic Sea on the SW., where Croatia has a seaboard of about 84 miles, and Hungary on the NE. Area, 16,352 sq. m., of which 5246 is Croatian, 3707 Slavonian, and 7399 belongs to the district of the military frontier. Pop. (1881) 1,892,499, Croatia having 816,802, Slavonia 377,613, and the former Frontier 698,084 inhabitants; in 1886 the total population had increased to 2,025,996. The surface of Croatia falls mainly into the wooded mountain district to the north of the Kulpa, with offshoots from the south-east Alps, and a calcareous plateau, belonging to the Karst region, to the south. To the Alpine system belong the Matzel, Ivinica, and Kalnik groups in the north; to the Karst system belong

the Liburnian Karst (5007 feet), along the coast from Fiume to Novi, and the Velebit Mountains to the south-east, with the peak of Sveto Brdo (5751 feet) near the Dalmatian frontier. The province belongs to the basin of the Danube, its most important rivers being the Drave and Save, with their affluents; the Gatschka, Likka, and others belong to the Karst, and the Zermanja, in the south-west, flows into Dalmatia. In Slavonia extensive marshes are found along the main rivers. Warm mineral springs are numerous, and earthquakes, especially about Agram (q.v.), are frequent. The Adriatic coast is poorly supplied with harbours, and exposed to the blasts of the Bora (q.v.). The climate along the coast and in the north is mild, Fiume and Agram having respectively a mean temperature of 60° and 52° F.; in the Karst the yearly mean is from 43° to 46° F.

The soil is in general very productive. Corn, maize, pulse, millet, flax, hemp, tobacco, and grapes are cultivated; large quantities of wood are exported, the rich forests being for this industry recklessly despoiled; and horses and cattle are successfully raised, while the oak-forests of Slavonia support great droves of swine. Silk-culture is progressing, and bees are largely kept in the heath districts. Only in ores and minerals is the province poor; iron, silver, copper, lead, zinc, sulphur, and coal are all worked, but in small quantities. Much of the weaving is done at home, and the other manufactures are not important. The trade is chiefly in land products, Slavonia exporting also a brandy made from plums. The bulk of the people are Slavs; both Croats (originally *Chorvats*, 'mountaineers,' from *choru* or *gora*, 'a mountain') and Slovenes are tall and strong, honest, and good-natured, holding much of their land in common, and dwelling for the most part in scattered hamlets. In the west the religion is Roman Catholic, embracing 71 per cent. of the entire population; in the east, that of the Greek Church. Education is very backward; in 1880, over 72 per cent. of the inhabitants could neither read nor write. A number of railways, however, now penetrate the country, and the interest in education and in the national language and literature is visibly increasing.

Croatia and Slavonia were for the most part included in the Roman province of Pannonia; in the 7th century the territory was taken possession of by the Slavonic races. The Croats shook off the Byzantine yoke about 900, and in the following century extended their rule over Dalmatia, built a strong fleet, which they employed first for piracy, and afterwards for trade, and had their king, Dirzislav, recognised by the Eastern court in 994. His son, Cresimir Peter, one of the greatest national heroes, was acknowledged as king of Dalmatia, as were also his successors until 1091, when the kingdom was taken over by Hungary. Slavonia was made a province of Hungary about the same date, but in the 17th century a great part of the land was held by the Turks, who only in 1699 resigned all territory north of the Unna. Croatia, Slavonia, and Dalmatia were united as the kingdom of Illyria from 1767 to 1777. Afterwards Croatia and Slavonia were regarded as part of the kingdom of Hungary; but among the Croats a feeling of hostility to the Magyars grew up, which asserted itself in 1848-49. In reward for Croatia's services during the Magyar revolt, it was declared independent of Hungary, and practically so remained until 1868, when the connection with Hungary was restored, Croatia sending deputies to the Hungarian diet. There must be a Croatian in the Hungarian ministry; there is a national diet at Agram, and the official language is Croatian. In 1883 there was a popular move-

ment, with riots, directed against the subordination to Hungary. The Military Frontier, established along the Turkish border in the 16th century, arose out of the necessity of perpetual defence. It was inhabited by military colonists who enjoyed special privileges, maintained regular armed posts, and were able to raise a force of 100,000 men on the briefest notice. This region was in 1881 finally incorporated with Croatia and Slavonia. Since 1886 the whole province, with the former frontier district, has been divided into eight counties, with Agram as capital. See **SERBIAN LANGUAGE AND LITERATURE**; also **BAN**.

Crochet (Fr., 'a hook'), a species of handiwork, which may be described as an extensive system of looping, by means of a small hook made for the purpose. Fancy worsted, cotton, or silk may be used as material, and a great variety of articles, from large bed-quilts to delicate lace-like edgings are produced in crochet-work.

Crocidolite, a mineral consisting mainly of silicate of iron in asbestos-like fibres. See **CAPE COLONY**, Vol. I. p. 735.

Crockets are ornaments used in Gothic architecture. They first made their appearance during the transition from Romanesque to Gothic in the 12th century, when they were introduced on capitals of columns in the shape of incurved bunches of

Crockets:

A. Choir of Notre Dame, Paris, circa 1180;
B. English crocket, 14th century. (Le Duc.)

leaves springing from stems in place of the classic volutes known before that date. Similar projecting crockets were soon applied to cornices, gables, spires, &c. In the Early English style they stand up in a stiffer manner, with the foliage at the point, but in the Decorated and Perpendicular styles the leaves are more developed and cling to the coping or rams to which they are applied as ornaments.

Crocodile (*Crocodilus*), a genus of reptiles which has also given its name to the small order

Crocodile.

(*Crocodylia*) to which it belongs. The order includes the largest living reptiles—viz. the crocodiles

proper, the Alligators (q.v.), and Gavials (q.v.). The most distinctive characters are as follows:

Externals.—The body, which is provided with a long, laterally compressed, crested tail, is covered with an armature of scales and dorsal bony 'scutes.' The latter exhibit a sculptured appearance. There are four short, strong limbs, with five fingers and four toes, which are webbed in various degrees of completeness. The three inner digits bear claws. Glands with a musk-like secretion are found on the margin of the lower jaw, at the side of the cloacal aperture, and on the posterior margin of the dorsal shields. The musky odour is strongest during the season of love. The nostrils lie close together at the point of the snout, and can be closed by valves; the eyes possess third eyelids, and the pupil is a vertical slit in nocturnal species; the tympanum of the ear is overhung by a fold of skin which closes during diving; the cloaca has a longitudinal aperture.

Skeleton.—Between the skull and the hip-girdle there are always twenty-four vertebrae; and behind the sacrum a large and variable number of caudal pieces. The vertebrae are prococious—that is to say, hollow in front—and bear ribs in the neck as well as in the thoracic region. The ribs are provided with two heads for articulation with the vertebrae, and those in the middle of the thorax give off hook-like, backward-turned (uncinate) processes which also occur in Birds (q.v.). A breast-bone, with which the thoracic vertebrae are connected, is always present, and behind this a number of posterior rib-like processes ('abdominal ribs') form a further support. These arise from ossification of septa between the muscles. In the breast-girdle the clavicle is absent; the hip-girdle is normal. In the large skull the chief peculiarity is the formation of a closed bony palate. By the internal union of premaxillae, maxillae, palatines, and pterygoids, the roof of the mouth is complete, and the posterior aperture of the nostrils is thus shunted back to the very beginning of the glottis. The development of the skull has been studied by Parker. The mouth-opening is very large, and the jaws bear numerous, usually conical, hollow teeth, implanted in distinct sockets, with reserve germs, at first on the inner side, and afterwards within the pulp cavities of the old ones.

The nervous system calls for no special remark. The peculiarities of nose, eye, and ear have been noted above. The animals have large lachrymal glands, and their 'tears' are proverbial. The tympana communicate with the mouth by three Eustachian tubes, one median and two lateral. As regards the alimentary system, the flat tongue is fixed to the floor of the mouth, the mouth-cavity is bounded behind by two soft transverse membranes. These meet when the crocodile is drowning a victim, and prevent water rushing down the throat. The stomach is in several respects like that of birds. The circulatory system is of importance, since in crocodiles for the first time the heart is four-chambered (see CIRCULATION). The partition between the ventricles is here complete, but as two aortic arches remain, mixed blood still goes to the posterior body. The left aortic arch carries only venous blood to the viscera, whereas in other reptiles it carries mixed arterial and venous. The pulmonary arch carries purely venous, the right aortic arch purely arterial blood. The right and left aortic arches communicate at their roots just outside the heart by a small aperture—the *foramen Panizzae*. The respiratory system presents no special peculiarity except in the backward shunting of the internal opening of the nostrils. When drowning its prey, and with its half-shut mouth in consequence open to the water, the crocodile keeps the tip of its snout on the surface, the glottis is pushed a little forward to meet the posterior open-

ing of the nostrils, a complete air channel is thus made, and respiration can go on unimpeded. The air is drawn into the lungs when the ribs expand, and an incipient diaphragm is also of use. The lungs are inclosed in pleural sacs. There is no urinary bladder.

Mode of Life.—Crocodiles are predominantly aquatic animals, and move rapidly by means of their powerful tail strokes. They are clumsy when ashore, and suffer from being stiff-necked. The body drags somewhat on the ground. They feed on fishes, especially in their youth, and on quadrupeds, which they catch by the river-side, and kill by drowning. If the prey cannot be readily torn, it is often buried till it begins to rot. For their shore work they prefer the darkness, but they also like to bask in the sun. They very often float in the water with their snout and upper back above the surface. The eggs, which are firm, though not thick-shelled, are laid in layers in holes on the banks. They are about the size of goose eggs, and the disproportion between the newly-hatched young and the adults is very striking. The females of some species are said to guard their young. Crocodiles are on the whole sluggish animals, and are very remarkable in the long continuance of the slow growth, which hardly seems to reach a limit as in other animals.

The crocodile has acquired in literature a character for deceitfulness which is largely undeserved. The conceit of 'crocodile's tears' (the animals have large lachrymal glands) was common in Shakespeare's time. Spenser describes (*Faerie Queene*, l. v. 18) the

Cruell craftie crocodile,
Which, in false griefe hyding his harmful gulle,
Doth weepe full sore, and sheddeth tender teares.

Another quotation given by Richardson (see Kitchin's edition of the *Faerie Queene*, Clarendon Press) is still more libellous, 'as cursed crocodile most cruelly can tole with truthlesse teares unto his death the silly pitieing soule.' Kitchin refers also to the invention of the adjective 'crocodilian' to express a depth of deceitfulness.

Different Forms.—The order of crocodiles includes twenty-five living species, distributed in three families and a doubtful number of genera. They are all found in tropical and warm regions. The three types may be thus contrasted:

Alligator.	Crocodile.	Gavial.
Nasal bones form part of nasal aperture.	As in alligator.	Do not.
Head short and broad.	Longer.	Very long.
Teeth very unequal. First and fourth lower teeth bite into upper pits.	Unequal. First into a pit, fourth into a groove.	Almost equal. First and fourth bite into grooves.
Union of lower jaws does not extend beyond fifth tooth.	Not beyond eighth.	At least to fourteenth.
Neck scutes distinct from back.	Sometimes distinct, sometimes united.	Continuous.
South America and south of North America.	Africa, India, North Australia, Cuba, South America.	Ganges, Borneo, North Australia.

There are altogether a dozen different forms of Crocodile proper, some of which have been dignified as separate genera. The crocodile of the Nile (*C. vulgaris*) is a well-known species, not now found farther north than Thebes, but occurring abundantly farther south and east. Several varieties are known. It is said sometimes to attain a length of 30 feet, though half that is considered large. It often fatally attacks man, and feeds very largely on smaller mammals. It grows very slowly and continuously, and, with the exception of man, has few formidable antagonists after

it has survived its youth. Some two or three score of eggs, with delicate rough liny shells, about the size of those of geese, are laid in sandy cavities in the bank. The young crocodiles are often happily destroyed by the ichneumon, and by a species of lizard. The adult crocodile lives in amiable partnership with a little bird (*Pluvianus aegyptius*). As Herodotus relates, this watcher warns the crocodile by its cry when danger threatens, and it also cleans its body of small animals which fix themselves there. The crocodile was worshipped and even mummified by the ancient Egyptians, and it occasionally bore a part in the Roman gladiatorial combats. It is now hunted for the perfume of its musk-glands, and also for its skin and fat. Crocodile-hide has lately increased in value as an article of commerce. The eggs are esteemed as dainty morsels. The most widely distributed species is *C. biporcatus*, or *porosus*. It occurs from the Mascarene to the Fiji Islands, from Farther India to Corea, and also on the north coast of Australia. It lives not only in fresh water, but ventures sometimes into the sea. A very large specimen in the British Museum measures 17½ feet in length. *C. frontatus*, in equatorial West Africa; *C. acutus*, in the north-west of South America, in Central America, and in the West Indies; *C. cataphractus* (often placed in a special genus, *Mecistops*), from the west coast of Africa, are other important species.

History.—These giant reptiles, like other large forms, have in recent ages been continuingly on the wane. They date from the Triassic period (Belodon, Parasuchus, and Stagonolepis—the last from the Elgin sandstones). In the Jurassic age they are very numerous, forty species having been recorded from British strata alone. In the Chalk, the first Crocodilia with anteriorly concave vertebrae appear in contrast to the Triassic, the Jurassic, and in part the Cretaceous forms, which had biconcave vertebrae. Among these Cretaceous forms are true Crocodiles and Gavials, which are also abundant in Tertiary strata. Professor Huxley has worked out the 'almost unbroken' series of gradations from the ancient Triassic forms down to the modern crocodiles, but where this series takes origin among the ancient reptiles is still obscure.

See ALLIGATOR, GAVIAL, REPTILE; also Duméril et Bibron, *Erpétologie Générale* (Paris, 1834-54); J. E. Gray,

Synopsis of Recent Crocodilians (Trans. Zool. Soc. Lond. vi. 1867); A. Heilprin, *Distribution of Animals* (Inter. Sc. Series, 1887, pp. 327-30); C. K. Hoffman, Bronn's *Thierreich*, vi.; Huxley, *Anatomy of Vertebrates* (1879); Journ. Linn. Soc. iv. (1860), &c.; *Nature*, xxxiii. (1885-86), p. 331; A. Strauch, *Synopsis der lebenden Krokodiliden* (Mém. Acad. St. Petersburg, x. 1866).

Crocus, a very beautiful genus of Iridaceae, all palaearctic, and particularly abundant in the Mediterranean countries and Asia Minor. Crocuses have long been cultivated in flower-gardens, particularly *C. vernus*, the purple crocus, with its many violet, white, or striped varieties; and *C. intus*, and other

Spring Crocus (*Crocus vernus*).

yellow species; all so welcome in early spring. The saffron crocus (*C. sativus*, see SAFFRON) and other

species flower in autumn. These must not be confused with the meadow saffron, often called autumn crocus (*Colchicum*, q.v.), which is a liliaceous plant, from which the true crocuses can at once be distinguished by their inferior ovary, and three instead of six stamens. *Bulbocodium vernum* is a pretty spring flower, also much resembling crocus, but closely akin to colchicum. Two species of crocus occur wild in England, *C. nudiflorus* and *C. vernus*, but the latter at least is merely naturalised. The flowers of one or two species are fragrant. Owing to the shortening and thickening of the stem, the ovary is subterranean, hidden among the leaf-bases, but in ripening it grows out upon a long thin procumbent pedicel, and thus deposits its seed at a sufficient distance from the parent plant. The thickened axis is a Corm (q.v.). It is necessary frequently to take up crocuses and plant them anew, on account of the manner in which the corms multiply. See CORM; and Mard, *Monograph of the Genus Crocus* (1887).

Crocus OF ANTIMONY is the oxysulphide of Antimony (q.v.). Crocus of Mars is the finely divided red oxide of iron.

Croesus, the last king of Lydia, succeeded his father, Alyattes, in 560 B.C. He made the Greeks of Asia Minor his tributaries, and extended his kingdom eastward from the Aegean to the Halys. From his conquests, his mines, and the golden sand of the Pactolus, he accumulated so much treasure that his wealth has become a proverb. He gave himself up in his court at Sardis to a life of pleasure and sumptuous extravagance, deemed himself the happiest man in the world, and was displeased when Solon, on a visit to his court, told him that no man should be called happy till his death. He soon found how uncertain was a happiness such as his; for his beloved son Atys was killed while hunting, and there was left to him only one son, who was dumb; whilst in his war with Cyrus he was totally defeated, his kingdom conquered, and himself made prisoner and condemned to be burned (546). At the funeral pyre, his repeated exclamation of 'O Solon!' struck the conqueror, who, when told the reason of it, spared his life and treated him with great kindness. As to his death, nothing is known.

Croft, William, musician, born in Warwickshire in 1677, was a chorister in the Chapel Royal, of which he became joint-organist in 1704, and sole organist in 1707. In 1708 he succeeded his old teacher, Dr Blow (q.v.), as organist of Westminster Abbey and choirmaster of the Chapel Royal; and in 1713 he took the degree of Mus. Doc. at Oxford. From 1704 Croft wrote a number of anthems for state ceremonies and public thanksgivings, thirty of which appeared in two folio volumes in 1724, and it is by these that he is now chiefly remembered. He died in 1727.

Crofter. The term crofter is commonly used in Scotland to designate a small tenant of land who derives a substantial portion of his livelihood from cultivation or the raising of live-stock. By the Crofters' Holdings Act of 1886, it is defined to mean the tenant of a holding who resides on his holding, the annual rent of which does not exceed £30 in money, and which is situated in a crofting parish.

Crofters may be broadly divided into two classes: (1) Those who occupy arable land in separate tenancy, and mountain pasture in joint tenancy; (2) those who occupy land in separate tenancy only. The first class may be denominated 'township crofters,' the second 'independent crofters.' The township crofters are by far the more numerous class, so much so that the joint tenancy of pasture is a characteristic feature of crofting life. They

are scattered over the whole surface of the Western Highlands and Islands, and over the whole of Sutherland. They are found in Caithness, Orkney, Shetland, and in the interior of Ross-shire and Inverness-shire, but less frequently on the eastern seaboard. The township crofters hold directly from the landlord, pay money rents, have had a preponderant share in the construction and maintenance of the buildings on the holding, and have been the authors of the greater part of the simple improvements on the holding and the township. They have preserved some marks of a primitive community in common rights and common obligations, and in the election of township officers who, by the custom of the estate, exert some authority in regulating the relations of the occupiers among themselves, and the relations between the occupiers and the landlord. The crofting township of the Highlands is a partial survival of a system of land-tenure once common to the whole of Scotland and prevalent in other countries. It has in all times existed in direct relations with the chief or landlord, yet the greater number of extant township crofters are the descendants of sub-tenants to the tacksmen of a former period, and were brought into immediate dependency from the proprietor in the 18th century. The township crofter has always been in the eyes of the law a tenant at will, whether holding under the landlord or the tacksmen, except in the case of a specific covenant to the contrary, but it is probable that during the prevalence of the clan system the mutual interests and affections of chief, tacksmen, and people, procured for the crofters the actual status of permanent tenure. While the crofters derive a material share of their livelihood and even of their food from the holding, their existence would be impossible without other sources of support. Among these fishing holds the first place and often affords the chief means of subsistence; but other local employments, domestic crafts, itinerant rural labour in the south, the earnings of a seafaring life, and remittances from relatives at home and abroad, all contribute to the crofters' maintenance.

The grievances from which the great mass of the township crofters have suffered may be enumerated as follows: The restricted area of holdings, and especially the reduction of common pasture land; high rents in exceptional cases; disturbance without due compensation; the molestation of deer and other game; the imposition of excessive local rates; the increasing burden of cottage dependents; want of harbours and defective means of transport to the centres of consumption. To these may now be added an unexampled depression in the value of agricultural produce, and a disastrous change in the methods previously used in the management of the fishing trade. The causes which have brought about such unhappy results are not far to seek. They exist in the covetous or mistaken policy of proprietors in the beginning of the present century, manifested by eviction and excessive consolidation of land; in the necessities of their successors; in the potato disease; in the too great subdivision of crofts; in the failure of the kelp manufacture; in the precipitate application of the Education Act in districts to which it was unsuited; in the apathy and improvidence which prevail among the crofters themselves; and, finally, in foreign competition in every department of industry. Such are the errors and neglects of the past; such the misfortunes of the present, which conspire to depress the crofting people. These hostile influences are intensified by the stormy climate, ungrateful soil, dangerous sea, and rugged irregular configuration of the Western Highlands. It remains to be proved in what degree such obstacles can be surmounted by legislative provisions conceived in the

interests of a class who with serious defects of character possess attractive and estimable qualities.

The independent crofters, who may be recognised as a distinct order among the crofting population, are found in all the Highland counties. They appear in considerable numbers in Argyllshire, in Caithness, in Orkney, in Shetland, and in the eastern parts of Inverness-shire and Ross-shire. They are more rare in Sutherland, on the western seaboard, and in the Hebrides. These laborious tenants have been recruited from the working-classes in adjacent districts, and from the members of broken townships dispersed by the formation of sheep farms. Established, for the most part, on waste lands under improving leases or stringent estate regulations, favoured in the eastern districts by a drier climate and soil, surrounded by the examples of a superior husbandry, and encouraged by assistance from the landlord, they have attained a higher condition than the crofting communities, both in regard to dwellings and tillage. The alleged grievances of the independent crofters have reference mainly to high rents, insecurity of tenure, and confiscation of improvements. Against such abuses they are now protected by the Act of 1886, from which they will derive substantial benefit.

In recording the diversities of crofting tenure it is necessary to mention the exceptional examples of freehold crofts with common pasture in the united parishes of Harray and Birsay in Orkney. These minute estates exhibit a marked superiority over yearly tenancies elsewhere. Belonging to a vigorous race of cultivators whose families prosecuted their fortunes in the colonies and on the sea, the Orkney freeholds have not suffered from excessive subdivision, and illustrate the advantages attached to stability and possession. It would be rash, however, to affirm that the institution of similar tenures would succeed equally well among the Celtic inhabitants of the western coast.

The comparative condition of the crofting people in the present and the past has been the subject of angry controversy. It seems not improbable that their state is now, in some respects, inferior to what it was in the age immediately following the fall of the clan system in 1746, while in others it is certain that the contemporary crofter possesses immunities and advantages of which his forefathers never dreamed. In favour of the older time may be alleged a larger share of the land, with a corresponding abundance of the necessities of life in seasons of plenty, more unrestricted access to the use of fish and game, freedom from local taxation, the existence of a graduated social order more harmonious and more congenial to the greatest number, the enjoyment of recreations native to the race, and that spirit of contentment or resignation which is associated with ignorance and isolation. It may, on the other hand, be contended, on behalf of the present, that the crofter is exonerated from personal services of an oppressive nature, that he obtains relief in scarcity, remedies in sickness, public support in infirmity and old age, elementary instruction, access to external labour markets, facilities for emigration, and that he possesses those aspirations and opportunities which belong to an expanded horizon of intelligence. When to the humane innovations of modern civilisation are added reduced rents and enlarged holdings, the crofting people will have little to envy in the precarious advantages claimed for their ancestors a century ago.

Moved alike by the recent sufferings, former wrongs, and threatening agitation of the crofters, the government of Mr Gladstone in 1883 nominated a Royal Commission to inquire into their condition. The commission conducted its investigations in the course of that year, and submitted its report in the

beginning of 1884. In May 1885 a remedial measure was introduced into the House of Commons which proved abortive, owing to the political incidents of the time; but the question was resumed in a more liberal spirit in 1886, when the Crofters' Holdings Act received the sanction of parliament and the crown. This statute embodies in substance the following provisions: The recognition of the 'crofting parish' as the area within which the act is applicable; security of tenure; fair rents; faculty to renounce tenancy; compensation for improvements; right to claim the enlargement of holdings; concession of testamentary powers in relation to the holding. And under this statute, three Commissioners were nominated to determine the areas within which the act shall be applicable, and to carry its provisions into effect.

In addition to these legislative enactments, the government has, in the appropriate administrative departments, initiated measures for the emigration of families from congested districts, the supply of fishing-boats and gear, the development of telegraphic communication, and the mitigation of the school-rate by increased grants.

The measures referred to, whether legislative or administrative, have been formed with an equitable consideration of the interests and rights of all parties concerned, and with a genuine desire to do good. The conditions by which they are surrounded are so complex, and the financial advances hitherto contemplated so restricted, that no immediate results of importance can be expected. A still graver impediment unhappily exists in the extreme poverty of the class whom it is desired to benefit.

Closely associated with the crofters by origin, avocations, and distresses, are the cottars. These people are occupiers of dwellings and small patches of ground, holding rarely from the landlord, more frequently from the farmer, the township, or the individual crofter, sometimes mere squatters, paying no rent and owing no allegiance. They exist by fishing, by casual employments on the land, and by public charity. Cottars are intermingled with their better-endowed kindred in all quarters of the crofting country, but they are most numerous and most miserable in the Long Island. Their claims are recognised by the Act of 1886, which grants them compensation for improvements in the case of arbitrary and voluntary removal.

The crofter and cottar population in the six counties to which the Act of 1886 applies were roughly computed by the Royal Commission of 1883 to comprise about 40,000 families, or 200,000 souls.

The Crofters Act of 1886 is applicable in crofting parishes only within the counties of Argyll, Inverness, Ross and Cromarty, Sutherland, Caithness, and Orkney and Shetland. Crofters' tenancies are diffused in other counties, especially in Aberdeenshire and Perthshire, but as they are subject to more favourable economic conditions, it was not considered necessary to admit them to the benefits of special legislation.

Croisic, LE, a small port on the Atlantic, in the French department of Loire-Inférieure, 20 miles W. of St Nazaire by rail. Once an important trading place, it has still a busy sardine-fishery, and is now becoming a popular watering-place. The name is familiar from Browning's *Two Poets of Croisic*. Pop. 2291.

Croker, JOHN WILSON, politician and man of letters, was born at Galway, 20th December 1780, the son of the surveyor-general of customs and excise in Ireland. After four years at Trinity College, Dublin, in 1800 he entered Lincoln's Inn, but in 1802 was called to the Irish bar. Two satires on the Irish stage and on Dublin society (1804-5) proved brilliant hits; so did his *Sketch*

of Ireland Past and Present (1807), a pamphlet advocating Catholic emancipation. In 1809 he published a poem on the battle of Talavera, which Wellington pronounced 'entertaining,' and during the same year helped to found the *Quarterly*, to which up to 1854 he contributed 260 articles. He had entered parliament for Downpatrick in 1807; and now in 1809 he was rewarded with the lucrative post of Secretary of the Admiralty for his warm defence of the Duke of York, who was charged with conniving at and sharing in the sale of army commissions by his mistress. That post he held till 1830, and then retired with a pension of £1500 a year. On the passing of the Reform Bill (1832), he refused to re-enter parliament, unable 'spontaneously to take an active share in a system which must subvert the church, the peerage, and the throne—in one word, the constitution of England.' He would not even take office under Peel, his old friend (1834); and with Peel he broke utterly on the repeal of the Corn Laws (1846). He died 10th August 1857. Among the seventeen works that he wrote or edited were his *Stories for Children from English History* (1817), which suggested to Scott the *Tales of a Grandfather*; the *Suffolk Papers* (1823); his *Boswell's Johnson* (1831); and *Essays on the Early Period of the French Revolution* (1857). By some Croker is chiefly remembered for his onslaught on Keats, and Macaulay's onslaught on him (Macaulay 'detested him more than cold boiled veal'); or as the originator of the term Conservative (q.v.); a founder of the Athenæum Club, and the 'Rigby' of Disraeli's *Coningsby*—the jackal of 'Lord Monmouth' (the Marquis of Hertford). But in Sir Theodore Martin's nine-page eulogy in the *Dictionary of National Biography* (vol. xiii. 1888), he figures as a 'debater of the first rank,' a master of 'rhetoric that eclipsed Macaulay's,' the 'friend and confidant of many of the best and ablest men of his time,' a pattern of 'sincerity,' 'consistency,' 'devoted loyalty and unselfishness.' See also his *Memoirs, Speeches, and Correspondence*, edited by Louis J. Jennings (3 vols. 1884).

Croker, THOMAS CROFTON, Irish folklorist, was born at Galway, 15th January 1798, and in 1814 was apprenticed to a Quaker merchant, but four years later clerkship in the Admiralty through John Wilson Croker, a friend, though no relation, of his father. He retained this post till 1850, and died at his home, 8th August 1854. As a boy of ten he began to collect songs and legends of the Irish peasantry; in 1818 he sent Moore more than forty old Irish melodies; and in 1825 published anonymously his *Fairy Legends and Traditions of the South of Ireland*, a work which charmed Schlegel and was translated into German by the brothers Grimm (1826). A second series followed in 1832, and the whole reached a 6th edition in 1882. Of more than twenty more works of which Croker was either the author or editor, the best were *Researches in the South of Ireland* (1824); *Legends of the Lakes* (1829), illustrated by his friend Maclean, and re-issued as *Killarney Legends* (1876); *The Adventures of Barney Mahoney* (1832); *A Memoir of Joseph Holt, General of the Irish Rebels* (1837); and *Popular Songs of Ireland* (1839; new ed. by Professor H. Morley, 1885). Croker was a zealous antiquary, a member of many learned societies. See the Life by his son, prefixed to the 1859 edition of the *Fairy Legends*.

Croll, JAMES, physicist, was born in 1821 near Coupar-Angus, in Perthshire. He received an elementary school-education, but in science was wholly self-trained. Successively millwright, insurance-agent, and keeper of the museum of Anderson's College, Glasgow, in 1867 he joined the staff of the

Geological Survey of Scotland, from which he retired in 1881. He is LL.D. of St Andrews, and F.R.S. Besides many papers in the *Philosophical Magazine* and other scientific journals, he has written *The Philosophy of Theism* (1857), *Climate and Time* (1875), *Discussions on Climate and Cosmology* (1886), and *Stellar Evolution* (1889). *Climate and Time*, one of the most important contributions to geological climatology, worked out in detail the view with which Croly's name is identified, that, contrary to the opinion of most physicists, changes of the earth's climate, such as the glacial periods, are due to the secular variations in the eccentricity of the earth's orbit, together with consequences arising out of them, such as the deflection of ocean currents. See CLIMATE, GLACIAL PERIOD, PRECESSION.

Croly, GEORGE, poet, romance-writer, biographer, and preacher, was born at Dublin in 1780, and educated at Trinity College there. He took orders in 1804, and in 1810 came to London, where, after twenty-four years of literary labour, he in 1834 became rector of St Stephen's, Walbrook. He died 24th November 1860. Between 1817 and 1858 Dr Croly published some forty works—the best known being the romance of *Salathiel*. See the Memoir prefixed to his *Book of Job* (1863).

Cromarty, the county town of Cromartyshire, on the southern shore of the Cromarty Firth, 2 miles from its entrance, and 19° NNE. of Inverness. Nothing remains of the old stronghold of the Urquharts, the most famous of whom was Rabelais' translator, Sir Thomas. From him the estate came to the second son of that Sir George Mackenzie who in 1685 was created Viscount Tarbat, and in 1703 Earl of Cromarty—a title forfeited by the third earl for his share in the '45, but revived in 1861 in favour of his descendant, the Duchess of Sutherland, who, dying in 1888, was succeeded therein by her second surviving son, Francis. In 1859 a statue was erected of Hugh Miller (q.v.). The population has dwindled from 2215 in 1831 to 1352 in 1881, though with Wick and four other burghs Cromarty still returns a member to parliament.—**CROMARTY FIRTH**, a land-locked inlet on the north-east coast of Scotland, extends 19½ miles north-eastward and eastward to the Moray Firth, and is inclosed by the counties of Ross and Cromarty. It forms a noble harbour, 1 mile to 7½ miles broad, and 5 to 35 fathoms deep; receives at its head the Conon; and narrows at its entrance to 7 furlongs, between the beetling North and South Sutors, 400 and 463 feet high. On its shores are the towns of Dingwall, Invergordon, and Cromarty (the last has declined with the rise of the second); the old red sandstone near its mouth is classic as Hugh Miller's hunting-ground.—**CROMARTYSHIRE**, a Scottish county, 369 sq. m. in area, but consisting of ten detached portions, and scattered up and down Ross-shire (q.v.), of which, for census and other purposes, it practically forms part. It comprised the ancient sheriffdom of Cromarty, and outlying bits annexed thereto towards the close of the 17th century at the instigation of Viscount Tarbat, who wished thus to hold jurisdiction over every part of his estates.—See Sir W. Fraser's *Earls of Cromarty* (2 vols. 1876).

Cromdale, a place in Elginshire, on the right bank of the Spey, 5 miles NE. of Grantown. Here, on 1st May 1690, 800 Jacobite Highlanders were surprised and routed by a body of King William's dragoons. This encounter is celebrated in a song called *The Haughs of Cromdale*.

Crome, JOHN (known as 'Old Crome'), landscape-painter, the chief member of the 'Norwich School' of artists, was born in that city, the son

of a poor weaver, 22d December 1768. After serving as an errand-boy to a physician, he was apprenticed to a house-painter; but, showing a strong predilection for art, he was befriended by Mr T. Harvey, of Catton, who procured him employment as a drawing-master, and permitted him to study works by Gainsborough and the Dutch masters in his collection. He also received some instruction from Beechy and Opte. He was mainly influential in founding, in 1803, the Norwich Society of Artists, which held exhibitions from 1803, and of which he was president in 1808. He occasionally visited London, when he exhibited in the Academy and the British Institution; and a tour through Belgium and France in 1814 resulted in 'The Fishmarket on the Beach, Boulogne,' and 'The Boulevard des Italiens, Paris.' But his subjects were nearly always derived from the scenery of his native county, which, though founding his practice upon that of the Dutch landscapists, he treated in a singularly direct and individual fashion, painting trees, and especially the oak, with exceptional fidelity and beauty. His works realised only most moderate prices during the artist's life; but he is now recognised as one of the great names among English landscapists, and fine examples of his art fetch very large sums. Several of his oil-paintings, including the great 'Mousehold Heath,' are in the National Gallery; and among his other masterpieces may be mentioned 'Carrow Abbey,' 'View of Chapel Fields, Norwich,' 'Oak at Poringland,' 'The Willow,' and in the Fitzwilliam Museum, Cambridge, the 'Clump of Trees, Hautbois Common.' He also practised as a water-colour painter, but his works in this medium are rare; and a series of his etchings of 'Norfolk Picturesque Scenery' was published in 1834, and has been repeatedly re-issued. The earlier impressions are fine and valuable. He died, 22d April 1821, at Norwich, where, in the following year, a collected exhibition of his works was brought together, and he was fully represented in the Royal Academy Old Masters Exhibition, 1878. His eldest son, John Bernay Crome (1794–1842), painted landscapes in a style similar to those of his father, as whose productions they are frequently sold.

Cromer, a pleasant watering-place on the coast of Norfolk, 23 miles N. of Norwich by a railway opened in 1877. The sea has here made great encroachments on the cliffs since 1350, though the town itself is now protected by a sea-wall, formed in 1877, with an esplanade and a jetty, at a cost of nearly £10,000. There are capital sands and golf-links (1887), and the church has a noble flint-work tower of 160 feet. Pop. of parish, 1597. See W. Rye's *Cromer Past and Present* (1888).

Cromlech (from the Gaelic *crom*, 'curved,' and *leac*, 'a stone') is a modern term, formerly applied by British archaeologists to a class of megalithic monuments, consisting of one flat stone supported on two or more upright stones, and forming a kind of open chamber with a roof. It is now generally recognised, however, that these are merely the denuded or uncovered chambers of chambered Cairns (q.v.) or Barrows (q.v.), for which another modern term, 'dolmen,' is now generally substituted (see DOLMEN). The French archaeologists retain the use of the word cromlech, but they have always applied it to those groups of standing stones which in Britain and Scandinavia are called Stone Circles (q.v.).

Crompton, SAMUEL, whose invention of the spinning-mule entitles him to rank as one of mankind's greatest benefactors, was born, the son of a small farmer, at Firwood, near Bolton, Lanca-

shire, December 3, 1753. Like his father, Crompton was brought up to the loom and the farm. His mother, a woman of great energy, perseverance, and stern independence, when left a widow struggled hard to give him and her two daughters the best education the district afforded. When he was old enough, he assisted her in the farm, and wove, and earned a little money by playing the violin at Bolton theatre. At the age of twenty-one, he was so much annoyed at the breaking ends of yarn and the difficulties in getting it to weave that he set to work to invent a spinning-machine which should produce better yarn than Hargreaves', one of which his mother possessed. For five years he laboured to realise his idea, sitting up late at night to overcome the successive difficulties, and resuming his labour for daily bread early in the morning. In 1779 he succeeded in framing a machine which produced yarn of such astonishing fineness that the house was beset by persons eager to know the secret. He was rendered miserable. All kinds of devices were tried to gain admission; even ladders were placed against the windows. His machine was such that if a mechanic saw it, he could carry away the leading features of it. He could not leave the house for fear of his discovery being stolen from him. He had spent every farthing he had in the world upon its completion; he had no funds wherewith to obtain a patent, and his shy and unbusiness-like temperament prevented him profiting as he should have done by his invention. A Bolton manufacturer persuaded him to disclose the invention to the trade, under the promise of a liberal subscription, but all that he got was £67, 6s. 6d. Soured by this treatment, in the course of time he saved money enough to begin manufacturing on a small scale at Oldhams, near Bolton, and latterly at Bolton, but not till his rivals had a hopeless start of him in the business. After the use of the mule had told distinctly on British manufacturing prosperity, a sum of between £400 and £500 was raised for him by subscription, through Mr John Kennedy, his earliest biographer. Efforts were made to procure for him a national reward. Five thousand pounds was all he obtained in 1812, and he returned to Bolton almost broken-hearted. He began the bleaching trade at Over Darwen, then became a partner in a cotton firm, but was unsuccessful in both. Some friends latterly purchased an annuity of £63 for him. He died June 26, 1827. Crompton's was soon by far the most used of all spinning-machines, and in 1811 the number of spindles on his principle was 4,600,000, while there were only 310,516 of Arkwright's, and 155,880 of Hargreaves'. A monument was placed over his grave, and in 1862 a bronze statue of him erected at Bolton. See Kennedy's *Memoir* in vol. v. of *Memoirs of Literary and Philosophical Society of Manchester*, and French's *Life of Crompton* (1860).

Cromwell, OLIVER, Protector of the Commonwealth of England, Scotland, and Ireland, was born at Huntingdon, April 25, 1599. He was the son of Robert Cromwell, younger son of Sir Henry Cromwell, descendant of a nephew of Cromwell, Earl of Essex, and was a younger brother of Sir Henry Cromwell of Hinchinbrook. His mother was Elizabeth, daughter of Thomas Steward of Ely, afterwards knighted by James I., who, when she married Robert Cromwell, was the widow of William Lynne. He was first-cousin to John Hampden. He was educated at Huntingdon grammar-school, the master of which was the Puritan Dr Beard, and at Sydney-Sussex College, Cambridge, and seems to have carried away a modest share of classical and general culture. He went to London to study law, but never

entered an Inn of Court. In June 1617 his father died, leaving him a moderate estate at Huntingdon. In August 1620 he married Elizabeth, daughter of Sir James Bouchier, a London merchant. Of the wildness of his youth there is no proof beyond his own remorseful confession after his conversion that before he knew God he had been the chief of sinners. He was, however, under medical treatment for hypochondria. He embraced Puritanism in its most enthusiastic form, attended and supported the ministry of its proscribed preachers, and became a zealous adherent of the cause, and opponent of its arch-enemy and persecutor Laud.

In 1628 he sat as member for Huntingdon in the stormy third parliament of Charles, and raised his voice against Romanising ecclesiastics. The parliament dissolved, he returned to farming at Huntingdon, whence he removed to St Ives and afterwards to Ely, where property had been left him by his uncle. He appears to have come into collision as a local patriot with the king's commissioners for the drainage of the Fens. He sat for Cambridge in the Short Parliament and in the Long Parliament (1640). In the Long Parliament, though no speaker, he was active and vehement on the Puritan side. Sir Philip Warwick describes him at this period in 'a plain cloth suit, which seemed to have been made by an ill country tailor; his linen was plain, and not very clean; and I remember a speck or two of blood upon his little band, which was not much larger than his collar. His hat was without a hat-band; his stature was of a good size; his sword stuck close to his side; his countenance swollen and reddish; his voice sharp and untunable; and his eloquence full of fervour.' Sir Philip adds: 'It lessened much my reverence unto that great council, for this gentleman was very much hearkened unto.'

When war broke out (1642) he was sent down to organize his district for the parliament, which he did with the greatest vigour and success. He also subscribed £500 to the cause. Becoming captain of a troop of parliamentary horse, he fought at Edgehill. After Edgehill, he warned his friends that the parliament must have soldiers of a better stamp, and that to the spirit of a chivalrous gentry must be opposed that of a God-fearing yeomanry. On this principle he formed his unconquerable Ironsides. With strict morality and organised enthusiasm he commanded in the famous corps a rigid discipline, which enabled him always to keep his troops well in hand, and thus to turn the wavering tide of more than one battle. While the cause of the parliament was depressed elsewhere, his constancy, capacity, and courage upheld it in the eastern counties, which had formed themselves into an association, of which he was the soul. A brilliant action near Gainsborough marked him for high command. In the summer of 1644 he, under Manchester, led the forces of the associated counties to join the Scots and the troops of the Fairfaxes before York, and in the battle of Marston Moor the charges of his cavalry decided the day. He now stood forth as the leader of the Independent and thoroughgoing party against the Presbyterians and moderates. After the second battle of Newbury he impeached the conduct of Manchester in parliament. While the Presbyterian and aristocratic generals were set aside by the Self-denying Ordinance, Cromwell was retained in command. Under Fairfax he led the new model army, of which he no doubt was the chief organiser, to decisive victory at Naseby, June 14, 1645. Fairfax, being no politician, Cromwell became the representative of the army in its contest with the Presbyterian parliament, which desired to disband it. The Presbyterians proving intractable,

he resorted as usual to strong measures, marched on London, and coerced the parliament. He was never revolutionary, but he cared not for forms when they stood in the way of what he thought right. It was no doubt under his directions that Joyce carried off the king from Holmby. It seems that Cromwell desired, had it been possible, to make terms with the king; but Charles was incurably possessed with the idea of recovering his power by playing off one party against the other. Whether it was by Cromwell or by the Scotch envoys that Charles was induced to fly from Hampton Court is a question on which authorities differ.

As a prisoner in the Isle of Wight, the king, while he was negotiating with the parliament, was carrying on intrigues with his partisans in England and Scotland, which brought on the second Civil War and the invasion of England by Hamilton. Again Cromwell was called to take the field for his cause, which was once more in extreme peril. After swiftly quelling the insurrection in Wales, he marched northwards, attacked the invading army of Hamilton at Preston and totally destroyed it. The soldiery now clamoured for justice on the king; and Cromwell, probably sharing their wrath and despairing of any arrangement with the faithless Charles, complied with their demand, brought the king to trial, sat in the High Court of Justice, and signed the death-warrant (January 1649). Had ambition been his motive for this deed we should hardly have found him at the same time treating for the marriage of Richard, his son, with the daughter of Mr Mayor, a private gentleman. The Commonwealth having been established, the first service rendered by Cromwell for it was the suppression of the formidable meeting of the Levellers, which he accomplished by a characteristic union of vigour with mercy. He was next sent to Ireland to end the civil war still raging there. This he did effectually, and on the whole humanely, though it cost some strokes of sanguinary severity, the necessity for which he himself deplored.

On his return from Ireland he (Fairfax having declined) took the command against the Scots, who had declared against the republic and called in Charles II. With his usual daring he assumed the offensive and invaded Scotland. But he was out-generalled by Leslie, and was in extreme peril, when a false move of the Scots by affording him battle, enabled him once more to display the superiority of the soldiery which he had trained and to win the decisive victory of Dunbar. The image of militant Puritanism was never more vividly presented than by Cromwell's bearing on that scene. With the defeated Covenanters he dealt as with estranged friends. The royalists proper, who still held the field in Scotland, having eluded his strategy and marched into England, he followed, and on September 3, 1651, at Worcester, gained the victory which he called his crowning mercy and which ended the Civil War. Returning to London in triumph, he declared for a constitutional settlement and an amnesty. The parliament, now reduced by revolutionary expulsions to the 'Rump,' was bent on perpetuating its own power. After fruitless negotiations Cromwell turned it out with unwise violence and contumely. Supreme power being now in his hands and those of the other chiefs of the army, he called the convention of Puritan notables, nicknamed the Barebones Parliament, for the settlement of the nation. The Barebones Parliament proving too visionary and revolutionary, was dismissed, and supreme power reverted to Cromwell and his officers.

Cromwell was now declared Protector under the instrument of government, which provided for a government by a single person with one House of

parliament elected on a reformed basis of representation, and a Council of State, in the appointment of which nomination by the Protector was combined with election by the parliament (December 16, 1653). A power of legislating by ordinance till parliament should meet was reserved to the Protector, and was largely used by Cromwell for the purposes of reorganisation and reform. His aim evidently was to restore in substance the ancient constitution of the realm, with a Protestant protectorate or monarchy, and full securities for liberty, especially for the religious liberty which had been in his mind at least the main object of the Civil War. But when parliament met, though elected under his writs, it fell to questioning his authority, and he was compelled to exclude the disaffected by a test. His second parliament, from which the recalcitrants were excluded at the outset, offered him the title of king. Cromwell wavered; but the stubborn resistance of the republican soldiers decided him to decline the offer. The Upper House of parliament was, however, restored, and the Protector was empowered to name his successor. A fixed revenue was also voted to him. He was now installed as Protector with a ceremonial resembling a coronation. When the parliament met again, its two Houses fell into a collision which compelled Cromwell to dissolve it; and his power thenceforth rested upon the army, though it was his constant desire to revert to constitutional government, and he was preparing to call a new parliament when he died.

His protectorate was a perpetual conflict with republican resistance on the one hand and with royalist plots and risings on the other, while his life was constantly threatened by royalist assassins. To keep down the royalists he for a time put the country under major-generals, supplying his treasury at the same time by an impost on the property of the cavaliers. He was, nevertheless, able to inaugurate a great policy, home and foreign. He reorganised the national church on the principle of comprehension, including all but Papists, Prelatists, and Antitrinitarians, while the ministry was weeded by commission, the result being, as Baxter, an opponent of the government, testifies, a ministry very acceptable to the people. Personally tolerant, Cromwell upheld toleration as far as he could, especially in the case of the Sec-tar-ies, and curbed the persecuting tendencies of parliament. For law reform he did his best, but professional interests were too strong for him. He united Scotland and Ireland to England, giving them both representation in parliament. Scotland, having free trade with England, enjoyed great prosperity under his rule. Ireland he sought to make a second England in order and industry, and if his measures were high-handed it must be remembered that the native Irish were then in an almost savage state. It was his aim to enlist ability, without distinction of party, and youths of promise from the universities into the service of the state. He saved the universities from the fanatics, put good men at their head, and encouraged letters.

But it is his foreign policy that has brought him most renown. Under him the Commonwealth became the head and protectress of Protestant Europe. He made peace with Holland and tried to form a league of all the Protestant states. He protected the Waldenses of Piedmont against their persecutors, using the pen of Milton in his protest. In the interest at once of religious liberty and commerce he allied himself with France, as the more liberal power, against Spain, the power of persecuting Roman Catholicism and the tyrant of the Western waters. He failed in an attempt on Hispaniola, but took Jamaica, and thus gave British enterprise a foothold in those seas. The

victories gained by his fleet under Blake over the Spaniards brought him at once glory and treasure. His troops, with those of France, won the battle of the Dunes, and he obtained Dunkirk as his share of the spoil. He sedulously fostered British commerce, and by the hand of Blake chastised the pirate-states of Barbary. His boast that he would make the name of Englishman as respected as that of Roman had been, was, so long as he reigned, fulfilled; and his bitterest enemies could not deny the impression which he had made on the world, or the height to which he had raised his country. His court was simple and frugal, yet dignified; and though there was a strain of coarseness in his character (as illustrated in occasional horseplay), his bearing in public upheld the majesty of the state.

Cromwell had always been a most loving husband and father, and the palace of the Protector was a virtuous English home. His speeches are very rough and unmethodical as compositions, but they are marked by sense, force, and intensity of purpose. He was fond of music, and not without regard for art. It seems that his government was striking root, since people of rank were beginning to ally themselves with it, and his heir succeeded without the slightest opposition. But disease and care, together with grief at the death of his favourite daughter, Lady Claypole, cut short his life. He died September 3, 1658, and the fabric of government which his mighty arm had sustained fell speedily to the ground.

The records of Cromwell's life are very imperfect. Of his greatness as a soldier and statesman there can be no question, but it is difficult across two centuries and a half to see into his heart and pronounce how far ambition mingled with higher motives. That the religious enthusiasm which sent him out to expose his life in war at the age of forty-three was sincere cannot be doubted; but religious enthusiasm is often associated with fanaticism and self-deception. One who knew Cromwell well has described him as 'in body compact and strong, about five feet ten in height, with a head which you might see was a vast treasury of natural parts, with a temper exceeding fiery but under strong moral restraint, and compassionate even to an effeminate measure.' 'A larger soul, I think, hath seldom dwelt in a house of clay than his was.' He was laid with great pomp in the tomb of the kings at Westminster, but after the Restoration his body was exposed on the gibbet at Tyburn and afterwards buried under it.

See Noble, *Memoirs of the Protectoral House of Cromwell* (1787); Cromwell, *Life of O. Cromwell and his Sons* (1820); Carlyle, *Cromwell's Letters and Speeches* (1846); Sanford, *Studies and Illustrations of the Great Rebellion* (1853); Goldwin Smith, *Three English Statesmen* (1867); Frederic Harrison, *Cromwell* (1888); and the works cited at ENGLAND and CHARLES I. and II.

Cromwell, RICHARD, second Protector, was the third son of Oliver, and was born October 4, 1626. He married Dorothy, daughter of Richard Mayor, of Hursley, in Hampshire. By the deaths of his two elder brothers, Robert and Oliver, he became his father's heir. He was an amiable and popular but weak man, devoted to field-sports and pleasure, and totally incapable of sustaining his father's burden. He lived for some time in comparative privacy, but when the Protector had been empowered to nominate his successor, Richard was brought to the front, and an effort was made to train him to the work of government, but in vain. Scarcely had he entered on his office, when the forces of anarchy, both parliamentary and military, broke loose, and he found himself utterly unable to restrain them. It was probably with little reluctance that he quitted Whitehall and retired into

private life. After the Restoration he lived for a time abroad under a feigned name; but he returned to England about 1680, and passed the remainder of his life at Cheshunt, where he died July 12, 1712, and was buried in the church at Hursley, Hampshire.

Cromwell, THOMAS (*malleus monachorum*, 'the hammer of the monks'), was born about 1485, the son of a Putney blacksmith, cloth-shearer, brewer, and innkeeper. His youth was turbulent and adventurous. During eight or nine years passed on the Continent (1504-12), he seems to have served as a common soldier, to have been befriended at Florence by Frescobaldi the banker, to have acted as clerk at Antwerp and to a Venetian merchant, to have visited Rome, and to have traded on his own account at Middelburg. Anyhow, by 1513 he was back in England and married; there, step by step, he rose to wealth and importance as a wool-stapler and a scrivener, half usurer, half lawyer, having originally been bred to the law. Wolsey employed him as early as 1514; through Wolsey, probably, he got into parliament (1523); he was Wolsey's chief agent in the unpopular work of suppressing certain smaller monasteries for the endowment of his colleges at Ipswich and Oxford (1525); and finally he became his factotum and secretary. He stepped to greatness over his fallen master. Cavendish tells how on All-Hallows Day, 1529, he found 'Master Cromwell saying of Our Lady matins—which had been since a very strange sight in him'—and bemoaning his own misadventure, but intending to ride from Esher to the court, 'where,' quoth he, 'I will either make or mar.' And Pole tells how, a few months earlier, Cromwell bade him take Machiavelli for his guide. Both stories illustrate the very man.

He was cheaply faithful to the cardinal, aiding him not only by quick-witted advice, and by pleading his cause in parliament, but even with £5 out of his own savings. Withal, he made himself friends of Wolsey's enemies; and his fidelity ingratiated him with Henry VIII. Him Cromwell promised to make the richest king ever in England, and counselled him to cut the knot of the divorce by declaring himself supreme head of the church. Counsel and promises were carried into effect by the Act of Supremacy (1534) and by the dissolution of the monasteries (1534-39). To abolish papal authority, break the power of the church, humble the nobility, and make the king absolute, were Cromwell's aims; in their accomplishment he stuck at nothing. At heart, it would seem, still a Catholic—for so late as 1535 he bequeathed £46 for a priest to sing mass for his soul—he yet did his utmost to Protestantise the English Church, whose 'polity,' in the words of Mr Froude, Cromwell's admirer, 'remains as it was left by its creator.' It is often hard to determine whether he was tool or instigator, to dis sever his actions from those of Henry; both must be treated under Henry's reign. But here may be noticed his winning manners and ungraceful person, his venality and profusion, his purposeful ruthlessness and ubiquitous industry, his army of spies and vast correspondence—above all, the fact that that English 'Terror,' in which perished More and Fisher and hundreds of lowlier victims, set in with Cromwell's rise, and ebbed with Cromwell's fall. Among the posts and honours showered on him were those of privy-councillor (1531), chancellor of the exchequer (1533), secretary of state and master of the rolls (1534), vicar-general (1535), lord privy seal and Baron Cromwell of Oakham (1536), knight of the Garter and dean of Wells (1537), lord great chamberlain (1539), and finally, on 17th April 1540, Earl of Essex. 'He had,' says Professor Brewer, 'engrossed in his own hands powers such as no subject and no sovereign in this country had ever

possessed before or will ever possess again.' But the hand that had so exalted could equally abase him. The hatred all men bore him, the Catholic reaction, and Henry's aversion to Anne of Cleves, the coarse Lutheran consort of Cromwell's choosing, combined to effect his ruin: less than eight weeks after his elevation to the earldom he was arrested and lodged in the Tower. His abject entreaties for 'Mercy, mercy!' availed him nothing; as little did his filthy revelations of Henry's discourse with him touching Anne of Cleves. Condemned under a bill of attainder, his own favourite engine of tyranny, he was bunglingly beheaded on Tower Hill, 28th July 1540. See Mr Gairdner's article in the *Dictionary of National Biography* (vol. xiii. 1888); Dean Hook's *Lives of the Archbishops of Canterbury* (vol. vi. chap. 1, 1868); Professor Brewer's article on 'The Royal Supremacy' in *English Studies* (1881); works cited under HENRY VIII.; and two articles in the *Antiquarian Magazine* for 1882 by Mr John Phillips of Putney, an ardent investigator of everything concerning Thomas Cromwell, who, according to him, has been 'vilely belied' by almost every writer on him, old and new.

Cronstadt, a strongly fortified Russian seaport, 20 miles W. of St Petersburg, on a narrow calcareous island 7 miles long, at the narrowest part of the Gulf of Finland, and over against the mouth of the Neva. Cronstadt is at once the greatest naval station and the most flourishing commercial port of Russia. It was founded by Peter the Great in 1710, the island having been taken from the Swedes by him in 1703. Its fortifications protect the approach to St Petersburg; the batteries are very numerous, defending every part of the channel by which vessels can enter. They are all built of granite, and armed with the heaviest ordnance. The place, indeed, was considered by Sir Charles Napier, who reconnoitred it during the Russian war of 1854-55, so impregnable that it would have been utter madness to make any attempt upon it. Cronstadt, which is the seat of the Russian Admiralty, has three harbours: the east, intended for vessels of war, and capable of accommodating thirty ships of the line; the middle harbour, where vessels are fitted up and repaired, and which is connected with the former by a broad canal; and the west, or Merchant's Harbour, for the merchant-shipping, with capacity for 1000 vessels. Since 1884 St Petersburg is connected with Cronstadt by a ship-canal 100 feet wide and 22 feet deep. Cronstadt contains many well-built houses, a cathedral, a statue of Peter the Great, and a British seamen's hospital (1867). Pop. (1880) 48,276.

Cronstadt, in Hungary. See KRONSTADT.

Cronus. See SATURN.

Crook, GEORGE, American soldier, born in Ohio in 1828, graduated at West Point in 1852, served in California till 1861, and was actively engaged throughout the civil war, in which he rose to the rank of major-general. He served against the Indians in Idaho (1866-72), in Arizona (1872-75), and crushed the great rising in Wyoming and Montana in 1875-77. In 1882 he returned to Arizona, where he controlled the Indians on the southern frontier, put an end to the truck system, and induced them to take up farms.

Crooked Island. See BAHAMAS.

Crookes, WILLIAM, a great physicist and chemist, born in London in 1832, was a pupil and assistant of Hofmann at the Royal College of Chemistry, next superintended the meteorological department of the Radcliffe Observatory, and lectured on chemistry at the Science College,

Chester. In 1859 he founded the *Chemical News*, and in 1864 became also editor of the *Quarterly Journal of Science*. He was elected F.R.S. in 1863, vice-president of the Chemical Society in 1876, member of council of the Royal Society the year after, and in 1880 was awarded by the French *Académie des Sciences* an extraordinary prize of 3000 francs and a gold medal. He is an authority of the first rank on sanitary questions, especially the disposal of the sewage of towns, and his method of producing extreme vacua gave a great impulse to incandescent electric lighting. His original researches in chemistry and physics led to the discovery of the metal thallium in 1861, of the sodium amalgamation process for separating gold and silver from their ores in 1865, and of important discoveries in molecular physics and radiant matter, besides the invention of the Radiometer (q.v.). He is the author of *Select Methods of Chemical Analysis* (1871), and of works on beetroot sugar manufacture, dyeing, and calico-printing, and has translated several works on chemical and metallurgical subjects.

Crop. See BIRD.

Cropredy Bridge, near Banbury, gives name to a battle (29th June 1644) between the royalists under Charles I. and the parliamentarians under Waller, when the latter received a check.

Crops. See ROTATION OF CROPS.

Croquet, an open-air game, in which two or more players endeavour to drive wooden balls, by means of long-handled mallets, through a series of arches set in the ground according to some pattern. The object of each player is to make the complete circle of six to ten hoops or arches; but during the course of the game he may have the progress of his ball retarded by his opponents, or assisted by his partners; and these friendly aids and hostile attacks constitute the chief interest of croquet. The game seems to be substantially a revival of the old game of Pall Mall, which gave its name to what is now the well-known London street, and to other places in England. Pall Mall, played with ball (Ital. *palla*) and mallet (Ital. *maglia*), came from France into England early in the 17th century, and died out in the 18th. Croquet (Fr. *croquer*, 'to crack') became a popular game about 1850, was the great summer social game during 1860-70, but was after about 1875 very largely superseded by the more active game of lawn-tennis. A *croquet-ground* should be a well-rolled level grass plat or lawn, not less than 30 yards long by 20 yards wide; a full-sized croquet-ground measures 40 yards by 30 yards.

Crosier, a staff 5 feet long, surmounted by a cross, and borne by or before an archbishop on solemn occasions. It is generally hollow, gilt, and richly ornamented. The crosier differs entirely from the Pastoral Staff (q.v.), with which it is often nevertheless confounded—the latter having a circular head, in the form of a crook. The illustration is of Archbishop Warham's crosier, from Canterbury Cathedral.

Cross. The cross was a common instrument of capital punishment among the ancients; and the death of the cross was esteemed so dishonourable that only slaves and

Crosier.

malefactors of the lowest class were subjected to it by the Romans. Among the Carthaginians, and probably also among the Phœnicians and allied races, it was employed as an instrument of sacrifice to Baal. Thus the Carthaginian general, Mæcus, invested his son, Cartalo, in royal raiment, with a crown on his head, and crucified him to obtain a special favour from Baal. It has been suggested that there may be some allusion to these crucifixions to the sun in Num. xxv. 4; Josh. viii. 29; x. 26. Among the Gauls, as shall be noted later, a cross of equal arms was a solar symbol. It was customary among the Romans to proclaim the name and offence of the person crucified, or to affix a tablet (*alburnum*) to the cross, on which they were inscribed. Malefactors were sometimes fastened on a simple upright stake, and so left to die, or they were impaled upon it, and to this upright stake the Latin name *cruz* was originally and more strictly applicable; but very generally a cross-piece (*patibulum*) was added to the stake, to which the arms of the criminal were tied, or to which his hands were nailed. When the cross-piece was fastened at right angles below the summit of the upright stake, the cross was called *cruz immissa*; when the cross-piece was fastened at right angles across the top of the upright stake, the cross was *cruz commissa*; and when it was formed of two beams crossing one another obliquely, it was *cruz decussata*. There was often a projection, on which the body rested, as on a seat. The cross was erected without the gates of towns, but in places of frequent resort. The person crucified often lived for days upon the cross.

The death of Christ by crucifixion led Christians to regard the cross with peculiar feelings of reverence, and to make use of the sign of the cross as a holy and distinguishing sign. The custom of *crossing* one's self in honour and commemoration of Christ, can be traced back to the 3d century. It was customary, probably from apostolic times, for the Christians to pray with extended arms; and Justin Martyr and Origen explain this attitude as representing that of Christ on the cross. In this manner Christians are represented in the early paintings in the catacombs, as praying. The Emperor Constantine, after obtaining the victory over Maxentius, through the influence, as he believed, of the sign of the cross, caused crosses to be set up in public places and upon public buildings; but the so-called cross of Constantine, or Labarum, was not really a cross, but a circle containing the XPI, the first three letters of the name of Christ in Greek, and was merely an adaptation of a symbol of a Gaulish solar deity (see Gailloz, *Le Dieu Gaulois du Soleil*), which consisted of a wheel of six spokes, or sometimes of four. After the *Invention of the Cross*, or finding of the alleged true cross of Christ in Jerusalem, which was supposed to have taken place in a search made on Calvary by the Empress Helena (q.v.) in 326 A.D., a surprising quantity of the relics of the cross were distributed through all parts of Christendom. When a portion of the cross was given to St Radegund by Justin II., emperor of the East, and she desired to have the relic received with honour into the city of Poitiers, the Bishop Maroveus peremptorily refused to allow it. She was obliged to appeal to King Sigebert, and he ordered the Archbishop of Tours to receive the relic. Maroveus left the town rather than countenance what he regarded as a superstitious act. For this occasion Venantius Fortunatus wrote the famous hymn 'Vexilla regis,' and it was first sung on the introduction of the relic processionally into Poitiers, circa 580. Various other protests were made against the extension of the worship of the relics, but in vain. The sign of the cross is made not only by Roman Catholics, but by the members

of the Eastern churches also; by the Westerns from left to right, by the Easterns from right to left. It is admitted by the Lutherans as a commemorative sign of the atoning death of Christ, but by many Protestants is rejected as a human invention in worship, and as tending to superstition. It was very generally used during the middle ages, and still is among the less enlightened peasantry in some Roman Catholic countries as a sort of charm, or as affording some security, like an amulet, against all evil; and particularly against evil spirits and witchcraft. The festival of the Invention of the Cross is celebrated on the 3d of May; that of the Elevation of the Cross commemorates the re-erecting of the cross at Jerusalem by the Emperor Heraclius in 628, after it had been carried away by the Persians. See *Legends of the Holy Rood*, edited by Richard Morris for the Early English Text Society (1871); and the *Legendary History of the Cross*, by Ashton and Baring-Gould (1887).

The earliest mention of representations of the crucifixion are by two writers in the 6th century. Gregory of Tours relates that such a picture was in one of the churches of Narbonne, and gave offence because it was nude; and the rhetorician Choricus says that in a church at Gaza was a representation of Christ crucified between two thieves. See CRUCIFIX. As neither of these writers remarks on the novelty of such representations, it may be supposed that they were not infrequent in the 6th century. Early crucifixes were, in contradistinction to that mentioned by Gregory, clothed to the feet. In the treasury of Monza are two such, one given by Gregory the Great in 599 to Adalwald, son of Queen Theodolinda, and another of the 6th century with a Greek inscription. The use of the cross without a figure of Christ is much earlier. As already mentioned, it was employed as a sign made with the hand, or by extension of the arms, at an extremely early Christian epoch; but no crosses are found represented in the catacombs of Rome before the 5th century, excepting the so-called cross of Constantine, *a*, which is not a cross, but a monogram. This symbol is found first in the beginning of the 4th century. It also took the form *b*. Then it became a plain cross, *c*. A very complete list of all the representations of the cross in its various forms in the Roman catacombs and other Christian monuments of the first five centuries will be found under the heading 'Kreuz,' in Kraus, *Realencyclopædie d. Christlichen Alterthümer* (1886).

It appears that the sign of the cross was in use as an emblem, having certain religious and mystic meanings attached to it, long before the Christian era; the *cruz immissa*, or cross with a handle to it, *c*, is common in Egyptian monuments. It was the symbol of immortality. The cross with equal arms, and the cross *st*, *d*, is a turned arms or fylfot, a historic symbol found on pubeswhere relics in Italy and elsewhere (see Mortillet, *Le Signe*, 1866). The Spanish *Croix avant le Christ* tried to find it an object of conquerors were astonished the natives of Central religious veneration among it was a symbol of the and South America, where

gods of rains. The forms given to crosses in art are endless; but the two leading types are one that on which Christ *cruz immissa*, supposed to have suffered, and the Greek cross, *f*, both of which are subject to many fantastic variations. The Greek cross forms the well-known sign of the English which was the national en-

previous to the union with Scotland. The cross of St Andrew, *g*, differed entirely in form from the Latin or Greek cross. This cross, or *crux decussata*, consisted of two shafts of equal length crossed diagonally at the middle, as in the annexed cut. According to the legend, this was the form of cross on which St Andrew, the national saint of Scotland, suffered martyrdom (see ANDREW). As the Scottish ensign, it is now blended with the cross of St George in the Union Jack.

The Cross of the Resurrection is a floriated cross; and is usually represented as heading a lance, to which is fastened a banner upon which a cross is depicted. The earliest and finest floriated cross is that in the mosaic of San Ponziano, where, however, the flowers spring from the shaft, and on the arms stand two lighted candles. The idea of the floriated cross seems to have been to connect it with Aaron's rod that budded, and so to signify the eternal priesthood of Christ.

In medieval times a cross, the Rood, stood over the screen between the nave of a church and the chancel. This was always veiled in Lent. The crutched cross, like the letter T, was the symbol of St Anthony the Hermit. *Processional* crosses are those carried in processions (see CROSIER); *pectoral* crosses, those worn on the breast by ecclesiastics of rank. Many orders have distinctive crosses. See LEGION OF HONOUR.

The Order of the Cross, originally a spiritual order of knighthood, sprang up in Palestine in the time of the Crusades, and was then called the *Bethlehemite Order*. Pope Gregory IX. confirmed the order in 1238. Its principal seat was in Bohemia. There is also a Brazilian Order of the Cross.

Sanctuary, Boundary, or Monumental Crosses, as they are called, consist of an upright flat pillar or obelisk, covered with sculptural devices, and set

Celtic Cross, most frequently found in Ireland and in the north and west of Scotland. Such crosses vary much, from a cross incised on a flat slab to an elaborate cruciform monument. The majority of the latter seem to belong to the period between the 12th and 15th centuries. One of the best known is that at Iona called St Martin's Cross, standing in the grounds of the cathedral. It is a column of compact mica schist, 14 feet high, 18 inches broad, and 8 inches thick, and is fixed in a pedestal formed out of a massive block of red granite, about 3 feet high. In connection with certain ancient religious houses in Ireland, there were very fine Celtic crosses. Some crosses of this type show Scandinavian workmanship; hence they are often called *Runic* crosses. The cross of Ruthwell (q.v.) in Dumfriesshire, and that at Bewcastle (q.v.) in Cumberland are interesting samples.

Churchyard Crosses seem to have existed in all churchyards before the Reformation: some still exist, and the remains of others are numerous. In France, in connection with the cemetery cross, in some parts, a perpetual lamp was kept burning, and the contrivance for the lamp remains in some of them.

Many very beautiful crosses exist in England, upon the points of gables of churches, or grave-stones, and in other situations, as also in heraldry. Among these, the cross most commonly seen is called the *cross crosslet* (see below).

Memorial Crosses are such as are erected in memory of a beloved object, or in commemoration of some event of local importance. In England there are some superb crosses of this kind; they are popularly called *Norman Crosses*. This species of cross resembled a Gothic turret set on the ground, or on a base of a few steps, and was decorated with niches for figures and pinnacles.

The best-known examples are those erected by Edward I. (1290) in memory of his queen, Eleanor; being placed on the spots where the body rested in its funeral progress to Westminster. The crosses at Waltham, Cheapside, and Charing were of the number. That at Charing was removed by the parliament in 1647; a modern reproduction now occupies its site. The Waltham Cross, restored in 1888, remains as a testimonial of the affection and piety of the greatest of the Plantagenets.

Village Crosses stood in the centre of most villages in ancient times. In the west of England a good many remain.

Town or Market Crosses were erected as stands to preach from, or in commemoration of events regarding which it was deemed proper to evoke pious

St Martin's Cross, Iona.

in a socket level with the ground. Occasionally, they appear to have marked boundaries, but more frequently were monuments over the graves of heroes, kings, bishops, &c. A vast number of extremely rude and early crosses of granite occur in Cornwall and Devon: some of these have apparently been fashioned out of prehistoric monoliths. In some instances, they probably marked the verge of a sanctuary. A characteristic type of cross is the

Waltham Cross, restored.

feelings. As these structures were incorporated with or surmounted by a crucifix, the term *cross* was so indelibly associated with them that it survived the religious character of the fabrics. The earliest examples of this kind consisted, probably, of tall crucifixes of wood, such as are still seen by the waysides in some continental countries. Afterwards, stone shafts would be substituted; and according to the increase of market revenues, or progress of taste, these town-crosses assumed that imposing character which they latterly possessed. The crosses at Cheddar in Somersetshire and at Malmesbury in Wiltshire, are open vaulted structures, with a commodious space beneath as a refuge for market-folks during rain, and surmounted with a kind of Gothic turret. At Chichester, Bristol, and Winchester, the market-crosses, while similar in form, are of a higher architectural quality. Adjoining St Paul's in London stood Paul's Cross, a structure which we read of as early as 1259, in the reign of Henry III. At this *preaching-cross*, by order of Henry VIII., preachers delivered sermons in favour of the Reformation, and here Queen Elizabeth attended to hear a thanksgiving sermon for the defeat of the Spanish 'Armada'; but in 1643 the cross incurred the displeasure of the Puritans, and was demolished by order of parliament. See *The Ancient Stone Crosses of England*, by Alfred Rimmer (1875).

Scotland offers no specimens of memorial or Norman crosses, unless it be the modern Scott Monument, at Edinburgh, which is essentially a Norman cross of a gigantic order. The simpler kind of Scottish market-cross consisted of a shaft of stone, standing on a flight of circular or octangular steps—the grander market-cross consisted of a tall stone shaft, on an imposing circular, hexagonal, or octagonal substructure, 10 to 16 feet high. The top formed a platform, which was surrounded with an ornamented stone parapet, and was reached by a stair inside. Losing their religious character, the

Scottish market-crosses were employed for royal and civic proclamations, and as places where certain judicial writs were executed. The oldest cross of Edinburgh stood in the centre of the High Street, but was removed in 1617. A new market-cross was then erected farther down the street, on the south side, which consisted of an octangular base, with a stone shaft of about 20 feet in height; its removal in 1756, by the civic authorities, is indignantly referred to by Scott in *Marmion*. The shaft, which had been preserved, was re-erected on a similar substructure near the same site in 1885, at the expense of Mr Gladstone.

CROSS, in Heraldry, is one of the ordinaries, and is represented with four equal arms, and considered to occupy one-fifth of the field if not charged, and one-third if charged. Argent, a cross gules, is the cross of St George. Like

other ordinaries, the cross may be *engrailed*, *inverted*, &c. When its central square is removed, it is said to be *quarter-pierced*; and when it does not extend to the margin of the shield, it is called *humettée*. But the cross of heraldry is often found varied in other ways, the varieties having each separate names. Thirty-nine varieties are enumerated by Guillim, and 109 by Edmonson. Those most frequently occurring are here mentioned; and it may be remarked that they St George's Cross, have rather the character of common charges than ordinaries not extending to the margin of the shield, and being often borne in numbers as well as singly. The *cross moline* (fig. 1) has the ends turned round both ways; the *cross fleury* (fig. 2) has each end terminating in a

fleur-de-lis; the *cross bottonnée* (fig. 3) has each end terminating in a trefoil; the *cross patonce* (fig. 4) has three points to each limb; the *cross patée* (fig. 5) is small in the centre, but widens towards the ends; the *cross crosslet* (fig. 6) is crossed at each end; and the *cross potent* (fig. 7) is crutch-shaped at each end. The *Maltese cross* (fig. 8), which converges to a point in the centre, and has two points to each limb, though not frequent as a heraldic charge, derives importance from being the badge of the Knights of Malta and other orders. Any of these crosses is said to be *fitchée* when the lower limb terminates in a point, as in fig. 9, representing a *cross patée fitchée*. Besides these and other crosses with equal limbs, there is the *cross Calvary* (fig. 10), being the cross of crucifixion elevated on three steps, and the patriarchal cross (fig. 11) with two horizontal bars.

Cross, MASON. See ELIOT, GEORGE.

Cross, SOUTHERN. See SOUTHERN CROSS.

Cross Bill, a bill of exchange or promissory note given in consideration of another bill or note.

Crossbill (*Loxia*), a Passerine bird in the finch family (*Fringillidae*), well known for the curious way in which the points of the upper and lower bill-halves cross one another. There seems to be no constancy in the direction of crossing, for in different individuals, even of the same species, the upper and lower portions are found variously directed to right or left. This peculiarity is probably for the most part a directly mechanical adaptation to the food-habit of the bird, which consists in tearing up the cones of firs and pines for the sake of the seeds. Bringing the two points together, the crossbill inserts its beak into the cone, then opens it with a strong lateral movement, and with its scoop-like tongue detaches and

Edinburgh Market-cross, 1617-1886.

captures the seed from the loosened cone. In a similar way, the crossbill can soon tear an ordinary cage to bits; or, which is more important, may rapidly do great damage by cutting up the apples in an orchard.

Crossbill (*Loxia curvirostra*).

It is interesting to compare two common species, *L. pityopsittacus* and *L. curvirostra*, since in the former the crossing of the bill is seen in a much less emphasised degree. The last-named species is of frequent, though inconstant occurrence in Britain, and two other species have been recorded as visitors. Altogether, seven species are known, from the northern regions of both hemispheres, and always found gregariously in conifer forests. The crossbill has become associated with a sacred legend, familiar to many from Longfellow's translation of a German poem on the subject. The bird was fabled to have sought, by pecking at the nails, to free Christ from the cross.

Crossbow, or **ARBALEST**, a weapon used in war and sport in medieval times. It consisted of a wooden stock, with a bow made of wood, iron, or steel, crossing it at right angles to the end; the bowstring was pulled down towards the other end of the stock by a lever (which in the simpler kinds was worked by hand or foot), and retained in position sometimes in a notch by a catch or trigger.

A, Hand Crossbow; B, Rolling-purchase Crossbow.

The bolt or 'quarrel' was then laid in a groove on the top of the stock, and the trigger being pulled, it was shot with a considerable amount of power. The latter, of course, depended on the size of the bow, some of the weapons being comparatively small and easily handled, while others were of large dimensions, and required a machine of the nature of a windlass, called a 'moulinet' or 'gaffe,' to enable the bow to be properly bent. The crossbows of the 14th century were almost all thus equipped. The 'quarrels' employed varied with the size of the bow, but generally they were short stout shafts about 18 inches long, winged with horn or leather, and having a metal point, which was sometimes sharp, but often lozenge-shaped, obtuse, and indented at the sides. Some crossbows had a tube or barrel, with a slit for the bowstring, and dis-

charged balls of clay, marble, or lead with such force that they were more formidable weapons than the earliest firearms. The larger crossbows were really military engines, which required several men to work them, and threw proportionally heavy missiles (see **BALLISTA**). The crossbow was used in England chiefly during the 13th century; after that it gave place to the longbow, which was found to be the more convenient and easily handled weapon of the two. Its use, however, was general among the continental nations of Europe after the 12th century; though the Lateran Council of 1139 forbade its use as being too murderous a weapon for Christians to employ against one another.

Cross-breeding. See **BREED**.

Cross-buns, a small cake specially prepared for Good-Friday, and in many towns of England cried about the streets on the morning of that day as 'hot cross-buns.' *Bun* is, according to Skeat, ultimately of Scandinavian origin. There is an Old Fr. word *bugue*, 'a swelling,' which may be the immediate source of the English word. Good-Friday buns were appropriately marked with the cross, and hence the name. The origin of the practice is obscure. Most probably it is a relic of some heathen observance, to which the early church gave a Christian significance. At Chelsea, there were formerly two celebrated bun-houses, besieged on Good-Friday from morning until night by hundreds of eager purchasers, but they have long since disappeared.

Crosse, **ANDREW**, electrician, born at Fyne Court, Somersetshire, 17th June 1784, was educated at Bristol and at Brasenose College, Oxford. His principal researches in science were as to the artificial formation of minerals by processes of electrical deposition and the application of electricity as a means of improving wines, cider, &c. In 1837 he announced that under certain circumstances, organisms (of the genus *Acarus*) appeared in solutions of inorganic substances; a discovery which attracted much attention, but which exposed him to the ridicule of opponents. He died 6th July 1855. See the *Memoir* (1857) by his second wife.

Cross-examination. See **EVIDENCE**.

Crossley, **SIR FRANCIS**, manufacturer and philanthropist, was born at Halifax, October 26, 1817. His father was the founder of the Dean Clough Carpet Mills. Sir Francis encouraged the inventor George Collier to produce a greatly improved carpet-loom; the mills increased till 6000 hands were employed; while carpets were much cheapened in price, and their use greatly extended at home and abroad. Amongst Sir Francis's benefactions to Halifax were a public park (1857) at a cost of £40,000, almshouses, and orphan homes, besides large donations to the London Missionary Society and to the Congregationalists. A baronetcy was conferred on him in 1863, and from 1852 till his death on 5th January 1872 he represented Halifax in the Liberal interest.

Crossraguel ('Cross of St Regulus'), a ruined abbey in Ayrshire, 2 miles SW. of Maybole. It was a Clugniac foundation, a daughter of the Paisley abbey, and dates from 1244. A notable 'disputation' took place in 1562 between John Knox and the abbot, Quentin Kennedy; and in 1570 the commendator was 'roasted' or severely tortured by fire by the Earl of Cassilis, to force him to resign certain lands. The charters of the abbey have been edited by F. C. Hunter Blair (2 vols. 1886).

Crotalaria (Gr. *krotalon*, 'a rattle'), a tropical genus of papilionaceous Leguminosae, deriving its

name from the inflated pods in which the seeds rattle when ripe. The species are annual, perennial, and shrubby plants, some of which yield valuable fibre, particularly *C. juncea*, the Sunn, or Hemp Sana, or Janupa Hemp of India, an annual species. The perennial *C. tenuifolia* (Jubbulpore Hemp) is grown in Southern India, and other species or varieties are in cultivation. Several species are North American.

Crotalidæ. See RATTLESNAKE.

Crotch, WILLIAM, composer, was born at Norwich in 1775. His musical genius was quite as precocious as that of the great Mozart. When little more than two years old he could play *God save the King* with chords, and in 1779 he was performing in London as a musical prodigy. When only twenty-two he was appointed professor of Music in Oxford University, and in 1822 he obtained the principalship of the Royal Academy of Music. Crotch composed a large number of pieces for the organ and piano, two oratorios, ten anthems, &c.; and he was author of *Elements of Musical Composition* (1812) and *Styles of Music of all Ages* (1807-18). He died at Taunton, December 29, 1847.

Crotchet. See MUSIC.

Croton, a genus of plants of the natural order Euphorbiaceæ, with numerous species, which are mostly tropical or subtropical trees or shrubs, a few herbaceous. The most important is the Purging Croton (*C. Tiglium*), a small tree, a native

Croton.

of India and the more easterly tropical parts of Asia. The leaves are extremely acrid; the wood in a fresh state is a drastic, and in a dried state, a more mild purgative; and the seeds (*Croton Seeds*, or *Tilly Seeds*) are a very powerful drastic purgative, formerly much employed in Europe, but latterly disused on account of violence and uncertainty of action, although still valuable as yielding croton-oil. They are oval or oval-oblong, about the size of field-beans. So great is their acridity, that dangerous effects have ensued from working for some hours with packages of them. The oil is obtained mostly by expression, and partly by treating the cake with alcohol. The wood and seeds of *C. Pavane* are employed in some parts of the East in the same way as those of *C. Tiglium*. Other species possess similar properties. Very different are the properties of the species which yield Cascarrilla (q.v.) and Copalchi (q.v.) barks. Other species are still more aromatic, and some

delightfully fragrant, containing in great abundance a thickish balsamic sap. The sap of *C. gratissimus* is employed as a perfume and cosmetic at the Cape of Good Hope; that of *C. origanifolium* is used in the West Indies as a substitute for Balsam of Copaiva; that of *C. balsamiferum*, also West Indian, furnishes *Eau de Mantes* by distillation; and the balsamic sap of some South American species is dried and used as incense. The *C. Draco* and other species yield a blood-red juice, which, when dried, forms the finest kind of dragon's-blood, and is possessed of astringent properties.

CROTON-OIL is the oil expressed from the seeds of the *C. Tiglium*, and is a sherry-coloured, viscid liquid, with an acrid taste, a somewhat rancid smell, and a fluorescent appearance. It contains a number of oily bodies, none of which have as yet been definitely shown to be the cause of its purgative and vesicating properties. Croton-oil is a violent purgative, in most cases a single drop being sufficient to remove constipation. When rubbed upon the skin it produces rubefaction and pustular eruption, and thereby tends to relieve some affections of the internal organs. It is used either by itself in the unmixed state, or diluted with olive-oil, soap liniment, alcohol, &c. It is not to be employed except under the advice of a doctor.

Crotona, a city of Lucania in ancient Italy, owed its origin to a colony of Achæans, as far back as 710 B.C. It soon became one of the most prosperous, wealthy, and powerful cities of Magna Græcia. Its walls measured 12 miles in circumference, and the territory over which it extended its sway was considerable. Its inhabitants were celebrated for athletic exercises, and they carried off most of the prizes at the Olympic games. Pythagoras settled here about the middle of the 6th century B.C., and became a very important member of the body politic (see PYTHAGORAS). About 510 B.C. Crotona sent forth an army of above 100,000 men, under Milo, its most renowned athlete, to fight the Sybarites; the latter, though three times as numerous, were utterly defeated, and their city destroyed. The war with Pyrrhus completely ruined the importance of Crotona, and in the 2d century B.C. it had sunk so low that a colony of Romans had to be sent to recruit its well-nigh exhausted population. It never afterwards recovered its prosperity. Some ruins belonging to the old exist in the vicinity of the modern city (called Cotrone, q.v.); and very fine Greek coins have been found. Cortona (q.v.) was also anciently called Crotona.

Croton River. See AQUEDUCT.

Crotophaga (Gr., 'tick-eater'), a genus of birds in the cuckoo family and order Coccothoracæ. They are also known by the names Ani and Keel-bird, the former referring to the cry, the latter to the blade-like ridge on the compressed arched beak. The best known of the three species (*C. ani*) frequents South America to the east of the Andes, and is often called the Savanna Blackbird. They are distinguished from other cuckoo-like birds by the tail, which has only eight steering feathers. The beak is as long as the head, and the keel is said to be used in unearthing their insect prey; the wings are long and pointed; the tail is long, broad, and rounded. They are social birds, and several females lay their eggs in a common nest. They are fond of keeping about herds of horses and cattle for the sake of the insect larvæ which they find on their skin. In this connection they are obviously of some importance.

Croup, a term used in Scotland from an early period to describe a certain train of laryngeal symptoms, was first applied by Dr Francis Home, in 1765, to an acute inflammatory and non-contagious affection of the Larynx (q.v.), in which there is the

formation of a false membrane or fibrinous deposit on the mucous surface of the windpipe. The invasion of the disease resembles that of simple Catarrh (q.v.), and may be very insidious. The child is languid, feverish, and thirsty, and a dry, shrill cough is gradually developed, but these symptoms sooner or later give way to those of the second stage. Here the respiration becomes difficult, the drawing of each breath having a hissing and 'croupy' sound; the voice is almost inaudible or greatly modified, and accompanied by a harsh, brassy, or may be stifled cough; the face is red and swollen, and covered with sweat; and the nostrils are rapidly working. If the little patient is not relieved by coughing or vomiting up some membranous shreds and glairy mucus, a state of greater dyspnoea ensues; the lips become livid and the nails blue; the fever is higher, the pulse quicker but weaker; and the child's efforts to relieve the increasing obstruction to the breathing are most distressing to witness. A period of extreme restlessness and suffering is (unless relieved by immediate treatment—see below) soon followed by death from increasing coma, syncope, or exhaustion.

Croup seems to be caused by a damp atmosphere of low temperature, and is got in exposed situations. It is most frequently met with between the years of two and ten, although all ages and classes are liable to suffer from it. It is commoner in boys than girls. Croup requires to be distinguished from simple catarrh of the windpipe; from so-called false croup, a spasmodic affection of the larynx—the Laryngismus Stridulus of Dr Mason Good; and from Diphtheria (q.v.), an infectious disease in which a false membrane is usually found on the pharynx or palate, as well as in the larynx. As croup is an acute and very fatal disease, the treatment requires to be active and decided. If the case is seen early, apply an ice-bag to the throat and give ice to suck, but if you suspect the presence of false membrane, give a full dose of an emetic, such as ipecacuanha, sulphate of copper, or sulphate of zinc, which should be repeated in three or four hours if necessary and effectual in relieving the breathing. The child should at intervals be placed in the hot bath, and inhalations of steam or medicated vapours administered. An inhalation of lactic acid is often of great use in the first stage. If these means fail, Tracheotomy (q.v.) must be at once resorted to, to save the life of the patient, as recommended by Trousseau.

Crow (*Corvus*), a genus of Passerine birds, and type of a family Corvidæ, which also includes Magpies (*Pica*), Nutcrackers (*Nucifraga*), Jays (*Garrulus*), Choughs (*Fregilus*), and other genera. The crow family is included in that Division of Passeres known as Acromyodi, from peculiarities in the vocal organs, and its members share the following characters: the bill is moderately strong and thick; bristles at the base cover the nostrils; the wings are of medium size and rounded; the tail is not prominent; the feet are strong. On the whole they outdo the other Passeres in size and strength, and are represented by towards two hundred species.

Keeping first to the crow genus proper (*Corvus*), we need give little description of the general characters of these familiar birds. The long black bill, the large gape, the tail all but covered by the wings, the black feet, &c. are well-known characteristics. The genus is distributed in most parts of the world except South America and New Zealand. They are essentially tree birds, and almost always build their nests there. In diet they are predominantly vegetarian. It is important to distinguish the four British species of crow. (1) The Raven (*Corvus corax*) is a well-known species in Europe and North Asia. Its black plumage has a

bluish sheen; the upper portion of the bill is bent over the lower; the wings reach the point of the tail. It is a hungry bird, devouring *inter alia* field-mice and small birds; it is not unfrequently tamed, and can be readily taught to ejaculate and play tricks. See RAVEN.

(2) The Rook (*C. frugilegus*) is a commoner smaller species of gregarious habit. There is the same metallic shimmer, the wings again reach the tail, but the upper bill is not elongated over the lower. The face becomes curiously bare during the first winter, and so remains. It is of use in destroying injurious insects, but its omnivorous appetite includes eggs, young birds, fish, walnuts, corn, &c. See ROOK. The accompanying figure

shows the heads of the raven, A, and the rook, B, and illustrates well the prevalent characters of the bill in this genus. It shows also in the raven the bristles which, as in most of the species, surround its base, but which are wanting in the rook. Noteworthy, too, is the greater strength of neck, head, and bill of the more carnivorous as compared with the more frugivorous species.

(3) The Hooded Crow (*C. cornix*) derives its name from the fact that while the general colour is ashen gray, the head is black. The under throat, the wings, and the tail are also, however, black. Like the next species, the hooded crow is fond of carrion, and both are often shot by gamekeepers on account of the damage they do to young game-birds, &c.

(4) The Carrion Crow (*C. corone*, or *Corone hiemalis*), which is of the same size as the rook, has black plumage, with a steel-blue shimmer on back and head, and wings which do not reach the tip of the tail. The bases of the feathers are gray in the rook, white in the carrion crow. It is useful in destroying mice and insects. It is said to interbreed with the preceding species. The name is given in America to a Vulture (q.v.). In some parts of Scotland the carrion crow is called the *Hoody*. There is considerable dispute as to the specific dignity of some of the crows. A few other forms in addition to the above four may be noticed. The crow of North America (*C. americanus*) is very similar to the carrion crow, but rather smaller, and, after the breeding season is over, congregates into great flocks; it is also partially migratory, great numbers from the more northerly parts moving to the south on the approach of winter. Its habits are otherwise intermediate between those of the carrion crow and the rook.—The Fish Crow (*C. ossifragus*) frequents the coasts and southern rivers of the United States, feeding chiefly on fish, which it catches with great dexterity. It also sometimes assails gulls, and compels them to disgorge their prey.—The Jabbering Crow (*C. jamaicensis*) of the Blue Mountains of Jamaica

is remarkable for the resemblance of its voice to human speech. Sir J. E. Tennent gives an interesting account of the small glossy gray-necked crow of Ceylon (*C. splendens*), which frequents the towns, feeding on offal, and boldly enters rooms through open windows, to snatch some morsel from the dinner-table. See also CHOUGH, JACKDAW, JAY, MAGPIE.

Crowberry, or **CRABERRY** (*Empetrum nigrum*), a small procumbent shrub, with characteristically inrolled leaf-margins, of the order Empetraceæ, a native of the colder northern parts of the world, abundant in the moors of Scotland and the north of England, and common throughout Canada, Alaska, and Siberia. The order consists of a few heath-like shrubs, which, however, are usually associated with Euphorbiaceæ (Spurges, &c.), with small trimerous unisexual flowers, the fruit a small

Crowberry (*Empetrum nigrum*):
a, flowering branch; b, flowers enlarged; c, fruit.

berry seated in the persistent calyx. The berries of the crowberry are nearly black, surround the branches in crowded clusters, and each contain six to nine bony seeds and a watery acidulous juice. A fermented liquor is prepared from them in some northern countries. They are a favourite food of game. *E. rubrum* of Cape Horn differs little, except in having red berries. The berries of the Camarinheira (*Corema alba*) are employed in Portugal for the preparation of an acidulous drink in fevers. The plants of this order, especially *E. nigrum*, have taken considerable part in the formation of peat.

Crowe, MRS CATHERINE (née Stevens), authoress, was born at Borough Green, in Kent, in 1800. In 1822 she married Lieutenant-colonel Crowe, and spent great part of her after-life in Edinburgh. She died in 1876. Her mind was morbid and despondent, ever hovering on the border-line of insanity, which it crossed once in one violent but brief attack. Her translation of Kerner's *Secrets of Prevorst* (1845) prepared the way for her well-known *Night Side of Nature* (1848), a great collection of supernatural stories, told, indeed, with vigour and verisimilitude, but hopelessly credulous and uncritical. She wrote also tragedies, juvenile books, and novels; of the last, the best, *Susan Hopley* (1841) and *Lilly Dawson* (1847). Her *Spiritualism and the Age we live in* (1859) has no value, save as autobiography.

Crowe, JOSEPH ARCHER, C.B., art-writer, born in London in 1825, studied and travelled widely on the Continent, where in 1847 he met Cavalcaselle; their joint works will be found in the article CAVALCASELLE. Crowe was a special correspondent in the Crimean war, the Indian mutiny, and the Franco-Austrian war; and in 1857-59 was director of the School of Art at Bombay. In 1860 he was appointed British consul-general at Leipzig, and afterwards at Düsseldorf; in 1882 he was made commercial attaché at Paris.

Crowfoot. See RANUNCULUS.

Crow Indians, a tribe of American Indians, belonging to the Dakota stock, and living on reservations in the valley of the Yellowstone, Montana. They are tall, well-made, and cleanly, with remarkably long hair; in 1868 they numbered about 3600.

Crowland, or **CROYLAND**, an ancient market-town in the south of Lincolnshire, on the Welland, in the Fens, 10 miles NNE. of Peterborough. Here in 716 King Ethelwald founded a monastery in honour of the hermit St Guthlac, which, burned by the Danes in 870, and again destroyed by fire in 1091, was restored in 1113, and thereafter became a mitred Benedictine abbey of singular magnificence. The north aisle of its church now serves as the parish church, and part of the west front also remains. Ingulph (q.v.) was abbot of Crowland. Pop. of parish, 2929. See G. Perry's *Croyland Abbey* (1867). The 'Triangular Bridge' is described in our article BRIDGE, Vol. II. p. 436.

Crown (Lat. *corona*). The crown of classical times was a circular ornament of metal, leaves, or flowers, worn on festive and solemn occasions, and as a reward of worth, talent, and military or naval prowess. Among the Greeks the crown (*stephanos*) was sometimes used as an emblem of office, as in the case of the archons; sometimes as an ornament for the heads of the victors in the public games; and sometimes as a mark of distinction for citizens who had merited well of their country. The Romans made great use of crowns as rewards for valour. The most highly prized was the *corona obsidionalis*, which was bestowed by a beleaguered garrison or army on the general who rescued them. It was made of grass or wild-flowers, gathered from the place which had been beset by the enemy. Next in order was the *corona civica*, a garland of oak leaves and acorns, which was given as a reward to any soldier who had saved the life of a Roman citizen in battle; the *corona navalis*, a gold circle decorated with beaks of ships, was the reward for naval services; the *corona muralis*, a similar circle surrounded with battlements, was bestowed on him who first scaled the walls of a besieged city; and the *corona vallaris*, a circle ornamented with palisades, on the first soldier who forced his way into the enemy's camp. There was also the *corona triumphalis*, bestowed upon a general when he obtained a triumph.

Other crowns were emblematical, such as the sacerdotal, funeral, convivial (of roses, violets, myrtle, ivy, and even parsley), and nuptial crowns. The custom of wearing bridal wreaths or even bridal crowns of metal is not unknown in modern Europe as in Germany and Norway and medieval England; and the bridal wreaths of young brides are still suspended in some Derbyshire churches. (1) *Corona sacerdotalis*, worn by the priests and bystanders when engaged in sacrifice. (2) *Corona funebris* or *sepulchralis*, with which the dead was crowned, a custom which prevailed both among the Greeks and Romans. In Greece, these crowns were commonly of parsley. (3) *Corona convivialis*, worn by guests on festive occasions.

As the emblem of sovereignty in modern Europe, the crown was borrowed less from the crowns of antiquity than from the diadem, a fillet of silk, linen, or woollen. This decoration was originally oriental. Alexander the Great adopted it from the kings of Persia; and Antony assumed it during his luxurious intercourse with Cleopatra. In modern states, crowns have been of various forms, and undergone various changes. The royal crown of England in the 12th and 13th centuries was a jewelled circlet of gold, heightened with strawberry-leaves or trefoils, sometimes alternately large and small. In the very costly and magnificent crown of Henry IV., the strawberry-leaves, eight in number, alternated with as many fleurs-de-lis, the whole alternating with sixteen small groups of pearls. The same crown was worn by Henry V. in the beginning of his reign, but on undertaking his French campaign he ordered it to be broken up, and the fragments distributed as security for the loan required by him to carry on the war. The crown that succeeded it was probably an arched one; for although no arched crown appears on the Great Seal of any monarch before Edward IV., the arched as well as the unarched form of crown is found occasionally in sculptures and illuminations of the reigns of Henry V. and Henry VI. The crown of Edward IV. (which was probably also worn by Henry V. and Henry VI.) differs from previous crowns in being arched over with jewelled bands of gold, closing under a mound ensigned by a cross patée, while crosses patée are substituted for the strawberry-leaves, and roses or fleurs-de-lis for the clusters of pearls. During succeeding reigns down to that of Charles II., the crown underwent various minor changes of form.

Fig. 1.

usually known in this country as the imperial crown, and represented in fig. 1. It has four crosses patée and four fleurs-de-lis set alternately

Fig. 2.

on the circlet, while two complete pearl-studded arches rising from within the crosses patée carry at their intersection the mound and cross. A new state crown was made for the coronation of Queen Victoria, differing somewhat from the imperial crown. Its arches rise almost perpendicularly, are elevated rather than depressed at their intersection, and assume the form of wreaths of rose, thistle, and shamrock, formed of brilliants; and the crown itself is covered with diamonds and studded with costly gems (fig. 2). In official representations of the royal arms, they are ensigned by the imperial crown, but a graceful modification of that crown is sometimes made use of instead of it with Her Majesty's sanction (fig. 3). For the coronets of the members of the royal family and of the nobility generally, see CORONET.

The crown of Scotland, long lost sight of, was in 1818 discovered, along with the other Regalia (q.v.), in a chest in Edinburgh Castle. Its gold circle, richly jewelled and enamelled, is heightened with ten fleurs-de-lis, alternating with as many crosses fleury, each adorned in the centre with a great diamond between four large pearls put crossways. Four gold arches, added in the reign of James IV., close under a mound, on which rests a large cross patée, with four pearls at the extremities, and as many in the angles. Excepting the arches, the crown is probably of the date of Robert Bruce.

In the crown of the kings of France the circle was heightened with fleurs-de-lis; and from the time of Francis I. it was closed with eight arches,

Fig. 3.

Fig. 4.

from whose intersection arose a fleur-de-lis. The crown of the former German emperors, now of the Austrian emperors, is cleft in the centre, so as to present an appearance suggestive of a mitre. The adoption of this crown by Charles V. seems to have resulted from the kings of France having, in emulation of the emperors, assumed a close crown. The iron crown of the ancient Longobardic kings (fig. 4)—restored to the king of Italy by the Emperor of Austria in 1866—is alleged to have been bestowed by Pope Gregory the Great on Queen Theodolinda, and with it Henry of Luxemburg and succeeding emperors were crowned. It is a gold circle with enamelled flowers and jewels, within which is a thin fillet of iron, which has been asserted to have been hammered from a nail of the true cross. The crown of the new German empire is shown in fig. 5. The crown with which the king of Roumania was crowned in 1881 was made of bronze from the cannon captured in the Plevna redoubts.

Fig. 5.

The crown of an English King-at-arms is of silver gilt, with sixteen oak-leaves, each alternate leaf higher than the others. Since 1727 that of the Scottish Lyon King-at-arms is similar in form.

Crowns frequently occur as heraldic bearings; of these there are three of the classical crowns noticed in this article—

Fig. 6.

viz. the *crowns mural*, a (fig. 6), *naval*, b, and *vallary*, c, also the eastern or antique crown, d, a circle with high points rising from it, and the celestial crown, differing from the last in having a star on each point.

THE CROWN is a term often employed to signify the state and the matters under control of the executive authority. Thus, in the interests of the state there are crown-ministers, crown-lawyers, crown-officers, crown-lands, &c.—the term, in no instance, having any special connection with the sovereign personally. In Scotland, certain high crimes are technically called Pleas of the Crown. These are four in number—murder, robbery, rape, and wilful fire-raising—and fall within the jurisdiction of the High Court of Justiciary. Likewise, in Scotland, there is a functionary styled crown-agent. He is a practising law-agent or solicitor, who, under the Lord Advocate and his deputed, takes charge of criminal proceedings. His duty is to receive from the procurators-fiscal of the different counties the precognitions which they have taken, and to lay these precognitions before the lawyers for the crown, that they may determine whether there is ground sufficient to call for a prosecution. He also expedites indictments and criminal letters, and otherwise discharges the duties of an agent in preparing and assisting in the conduct of trials before the High Court of Justiciary, which are generally superintended or conducted by the Solicitor-general. The appointment of the crown-agent is with the Lord Advocate, and ceases with the administration.

CROWN-SOLICITOR, the solicitor to the Treasury, who, in state prosecutions in England, acts as solicitor for the crown in preparing the prosecution. In Ireland there are crown-solicitors attached to each circuit, whose duties correspond in some degree to those of the Procurators-fiscal (q.v.) and crown-agent in Scotland. In England there are no analogous officers, and prosecutions are consequently conducted by solicitors appointed either by the parish, or by private parties bound over by the magistrates to prosecute. But in cases of great importance to the public, such as unusual or monstrous crimes, it is of frequent occurrence that the Solicitor to the Treasury takes charge of the case and instructs counsel.

CROWN DEBTS.—It is a prerogative of the crown to take precedence of all other creditors, and in England, to recover its debts by a summary process called an *extent*. By 33 Henry VIII., chap. 39, this preference is given over all creditors who have not obtained judgment (meaning in Scotland, the execution of diligence) for their debts before the commencement of the crown's process; and the Act 6 Anne, chap. 26, extended the law of England in this respect to Scotland, the old writ of extent being abolished in 1856. The rule in Scotland was limited to movable or personal property, and the crown has no privilege over a subject in a competition for heritage. It obtains, however, as opposed to the landlord's Hypothec (q.v.). Mercantile sequestration does not discharge crown debts except with consent of the Treasury; and in a sequestration the crown has a statutory preference for one year's arrears of income and property tax, and assessed taxes. A similar preference is given for local rates. See **EXTENT**, **EXCHEQUER**.

CROWN-LANDS must be distinguished from such rights as that in the seashore, which are merely held by the sovereign in trust for the people; and also from that portion of the royal patrimony which consists of such reserved rights as mines, salmon-fishings, &c. The crown-lands are called annexed property in Scotland, and demesne lands in England, and are of course also distinct from the private estate of the person who happens to be sovereign. They are now contracted within narrow limits, having been almost entirely granted away to subjects. King William III. so impoverished the crown in this manner, that an act was passed

in 1703 voiding all grants or leases from the crown of royal manors, or other possessions connected with land, for a period exceeding thirty-one years. At a much earlier period (1455, chap. 41) a Scottish statute had rendered the consent of parliament necessary to the alienation of the property of the crown, but the policy adopted of extensive subinfeudation to encourage agriculture had the effect of greatly diminishing the relative value of crown-lands not actually given away; and in Scotland they now consist mainly of a few castles, palaces, and feu-duties. The superintendence of such property as still belongs to the crown is now vested in commissioners appointed for the purpose, called the Commissioners of Woods, Forests, and Land Revenues. See **WOODS AND FORESTS**. In some British colonies unallotted ground is nominally crown-land. Thus the sale and settlement of land in New South Wales was regulated by the Crown Lands Act of 1884.

Crown, in Architecture, a species of spire or lantern, formed by converging flying-buttresses. Familiar examples in Scotland are the crowns of St Giles's, Edinburgh, and King's College, Aberdeen; south of the Tweed the only old crown is that of St Nicholas's Cathedral at Newcastle.

Crown Imperial. See **FRITILLARY**.

Crown Pieces of silver, of the value of five shillings, were introduced into the English coinage by Henry VIII. They have a standard weight of 436.56 grains. None were coined from 1861 till 1887, but since then they have again been struck. The name crown is also used as the translation of the French *écu*, which varied in value from 6 francs (or *livres*) to 3 francs.

Crown Point, a post-village of New York, on Lake Champlain, near the site of a British fort of the same name surprised and captured by Colonel Ethan Allen in 1775.

Crown-work, in Fortification, is an outwork consisting of two Bastion (q.v.) fronts connected with the main work by long flanks, so that its plan resembles somewhat the outline of a crown.

Crow's-feet. See **CALTHROP**.

Crow-stone, the top stone of the gable-end of a building. See **CORBIE STEPS**.

Crowther, SAMUEL ADJAI, Bishop of the Niger territory, whose native name is Adjai, was born in Gbogi, to the east of the kingdom of Dahomey, in 1812, was carried off as a slave in 1819, and after having been bartered and sold more than once, was taken by a British man-of-war and landed at Sierra Leone in 1822. He was placed under a missionary for training at Bathurst, and in 1825 professed his adherence to Christianity, taking his present name after a London vicar. He was next placed in charge of a mission school at Regent's Town, was with the first and second Niger expeditions (1841, 1854); visited London in 1842, when, as the result of some further training, he was ordained by the Bishop of London, entered with enthusiasm upon his missionary labours, and was consecrated Bishop of the Niger territory in 1864. He is D.D. of Oxford, author of several native tracts, and has translated the Bible into the Yoruba language. See his *Life* (1888).

Croydon, a town in Surrey, 10½ miles S. of London Bridge, yet practically a suburb of London. It lies on the edge of the chalk and plastic clay, near the Banstead Downs, at the source of the Wandle, hence its name *Croindene* (Fr., 'chalkhill') in Domesday. The archbishops of Canterbury had a palace here from the Conquest till 1757. Its Perpendicular hall (1452) and chapel (1633-63) were purchased by the Duke of Newcastle in 1887 and presented to the Sisters of the Church Extension

Association. Addington Park, $\frac{3}{4}$ miles ESE., has since 1807 been the summer seat of the archbishops. Addiscombe House, at one time the residence of the first Earl of Liverpool, was converted in 1812 into the East India Military College, but was pulled down in 1863. The fine old Perpendicular parish church was destroyed by fire in January 1867, with the exception of the tower, but was rebuilt by Sir Gilbert Scott, and retains the monument of Archbishop Sheldon, with fragments of that of Archbishop Grindal. That of Archbishop Whitgift was restored in 1888 at a cost of £600. Whitgift's Hospital (1596) is a red brick quadrangular pile, restored in 1860; whilst his grammar-school now occupies buildings of 1871, besides a large Whitgift middle school. Croydon was one of the first towns in England to grapple effectually with the question of the economical disposal of town-sewage. A system of disposing of sewage by irrigation was inaugurated in 1858, and the corporation now possess two sewage farms, comprising 680 acres. In 1868, owing to the rapid growth of the town, new water-works were completed, the water, which is of great purity, being obtained from an artesian well, yielding nearly 3,000,000 gallons per diem; and a further supply of 2,000,000 gallons per diem was introduced in 1888 at a cost of £50,000. The death-rate in 1848, the year before the adoption of the Public Health Act, was 28·16; in 1887 it was 14·71. There are thirteen railway stations. Till the 18th century Croydon was famous for its 'colliers' or charcoal-burners; now its chief specialty is the manufacture of church clocks and carillons. It was made a municipal borough in 1883, a parliamentary one in 1885, and a county borough in 1888. Pop. (1851) 10,260; (1861) 20,325; (1871) 55,652; (1881) 78,953.

Crozet Islands, a group to the south of the Indian Ocean, almost on a line between the Cape of Good Hope and Kerguelen's Land, in lat. 46° S., and long. 52° E. Except four or five, they are mere rocks, and are all uninhabited, though shipwrecked sailors have lived for a time on them. They were visited by the *Challenger* expedition in 1873-74.

Crozier. See CROSIER.

Crucian (*Carassius vulgaris*), a fresh-water fish, nearly related to the carp, from which it differs in the absence of barbules, in the single-rowed arrangement of the pharyngeal teeth, and in a few other minor points. It is found in numerous varieties in rivers, ponds, and lakes in Europe and Asia; and is sometimes, though rarely, caught in the Thames. The food chiefly consists of dead vegetable and animal matter. The flesh is less esteemed than that of carp. The fish spawn in May or June, and then assemble in great numbers. See CARP.

Crucibles (Low Lat. *crucibulum*; from the root of Old Fr. *cruche*, 'a pot') are vessels made of materials capable of being exposed to high temperatures without alteration, and used for fusing substances together, such as the materials for glass-making, or metallic ores, with various fluxes to obtain the several metals they yield. Crucibles should resist the corrosive action of the substances brought into contact with them, and are generally made of fireclay, porcelain, graphite, iron, platinum, and, for some special operations, of silver. See ASSAYING.

Crucible.

Cruciferae (Lat., 'cross-bearing,' from the X-wise position of the four petals), an important order of thalamifloral dicotyledons, including about 1200 known species, mostly palaearctic, and specially abundant in Europe. No order is indeed more

familiar or more widely represented; the Mustard, Shepherd's Purse, &c., are among the commonest weeds of cultivation, while the Turnip and Cabbage, the Radish and Cress, &c., are no less familiar and widespread in usefulness. As wild flowers, they are mostly inconspicuous, but the pretty Cuckoo-flower or Lady's Smock (*Cardamine pratensis*), and not a few others, might be mentioned as contributing some characteristic feature to marsh or cliff or copse; while a large number of genera are of the greatest value to the florist, for whom the exuberant masses of Iberis, Alyssum, Arabis, and Aubrietia are among the most admired resources of the rock-garden. Besides the Stocks and Wallflowers, &c., the old-fashioned Honesty and Gillyflower are among the most familiar inmates of every cottage-garden. The general character of the order is antiscorbutic and stimulating, with more or less acidity; the familiar flavour being due to the presence of a characteristic ethereal oil. Striking examples of these properties are given by the Scurvy-grass of our shores, so important to mariners in the days of long voyages and salt provisions; or more familiarly by the Common Water-cress; while a wide range of variation of flavour is presented by the flesh, rind, and leaves of the Common Turnip, especially in different varieties, soils, and seasons. A fixed oil is largely present in the seeds (see RAPE, COLZA), and the Woad Plant (*Isatis*, see WOAD) has been used from the earliest times as a source of indigo. The order was conveniently subdivided by Linnaeus by the nature of its fruit as long and short podded (*Siliquosae* and *Siliculosae*), while later systematists have derived important characters from the mode of folding of the cotyledons within the seed. See Engler's *Pflanzenfamilien*, or other systematic work, and separate articles—e.g. CABBAGE, &c.

Crucifix (Lat. *crux*, 'the cross,' and *figo*, 'I fix'), a cross with the effigy of Christ fixed to it. The principal crucifix in Catholic churches stands in the centre of the high-altar. It overtops the tapers, and is only removed to make place for the host in the service of Benediction. In well-appointed churches, the altar crucifix is generally either of gold or silver. Crucifixes are used in Lutheran churches, and in Prussia they are often made of Berlin iron. The crucifix first began to take the place of the plain cross in the time of Constantine, but it was never publicly acknowledged by the Greek Church, and did not come into general use in the East till towards the end of the 8th century. It was not till the Carolingian age that it became general in the Latin Church. On the earlier crucifixes, Christ is represented as alive, with open eyes, and generally clad, and fastened with four nails. On later ones he is represented as dead, naked, except for a cloth round the loins, and fastened with three nails—i.e. the two feet pierced by a single nail. See CROSS.

Cruden, ALEXANDER, born at Aberdeen, 31st May 1701, from the grammar-school passed to

Marischal College, where he took his M.A., but, having shown symptoms of insanity, was for a short time placed in confinement. On his release he left Aberdeen, and, after spending ten years as a tutor, in 1732 established himself as a bookseller in London. In 1737 appeared his *Complete Concordance of the Holy Scriptures*, a really admirable work. It was dedicated to Queen Caroline, who graciously promised to 'remember him,' but unfortunately died a few days later. Cruden now relapsed into insanity, and for ten weeks was kept in a mad-house, as again for a fortnight in 1753. Earning meanwhile his livelihood as a press-reader, he assumed the title of 'Alexander the Corrector,' and in 1755 began to go through the country, reproving by voice and pen the nation's sins of Sabbath-breaking and profanity. But many a good and kindly action was interwoven with his crack-brained courtships, his dreams of knighthood and a seat in parliament. He was just back from a visit to his native city, when he died at his prayers in his Islington lodgings, 1st November 1770. See the *Life* by A. Chalmers, prefixed since 1824 to many of the numerous editions of the *Concordance*. See CONCORDANCE.

Crucity. See ANIMALS (CRUELTY TO), CHILDREN (CRUELTY TO).

Cruikshank, GEORGE, one of the most gifted of English pictorial satirists, was born in London, September 27, 1792, the son of Isaac Cruikshank, who, as well as his eldest son, Isaac Robert Cruikshank, was also known as a caricaturist. Cruikshank at first thought of the stage as a profession; but some of his sketches having come under the notice of a publisher, he was induced to engage in the illustration of children's books and songs. A publication, *The Scourge* (1811-16), afforded scope for the display of his satiric genius, and from that time forth he continued to pursue with remarkable success this his true vein. His illustrations for Hone's political squibs and pamphlets, and especially those dealing with the Queen Caroline trial, attracted much attention, and sent some of them through no less than fifty editions. But in the exquisite series of coloured etchings contributed to the *Humorist* (1819-21), and in the etchings to the *Points of Humour* (1823-24), did his true artistic power begin to be visible. This second, and in many ways finest, period of his art, represented by these works, culminated in the etchings to *Peter Schlemihl* (1823), and to Grimm's *German Popular Stories* (1824-26), which in the simple directness and effectiveness of their execution, and in their fertile and unencumbered fancy, rank as the artist's masterpieces. The latter series, now extremely scarce, was reproduced in 1868, with a laudatory preface from the pen of Mr Ruskin. Similar in artistic aims and method are the spirited little woodcuts contributed to the *Italian Tales* (1824), *Mornings at Bow Street* (1824-27), and Clark's *Three Courses and a Dessert* (1830); and the plates to Scott's *Demonology and Witchcraft* (1830) may be regarded as the last examples of his earlier and simpler method as an etcher. His numerous plates in *Bentley's Miscellany* mark a third period of his art, in which he aimed at greater elaboration and completeness, introducing more complex effects of chiar-oscuro, and frequently attaining great power of tragic design. The finest of these are the great series to Dickens's *Oliver Twist*, and Ainsworth's *Jack Sheppard* and *The Tower of London* in *Ainsworth's Magazine*, and in the same class are to be ranked the plates to *Windsor Castle*, and *The Miser's Daughter*, of which, as of *Oliver Twist*, he thirty years afterwards claimed the chief authorship. Among the best productions of his later years are the large

and elaborate etchings to Brough's *Life of Sir John Falstaff*, published in 1858. His last illustration was the frontispiece to Mrs Blewitt's *The Rose and the Lily* (1877), 'Designed and etched by George Cruikshank, aged eighty-three, 1875.' As a water-colourist he left work marked by considerable skill and delicacy. In his late years he devoted himself to oil-painting, and in this province showed perhaps more humour, fervour, and inventive ability than artistic power. His most important picture was 'Worship of Bacchus' (1862), which has been engraved partly by his own hand, a vigorous and earnest protest against the evils of drunkenness; and to the cause of temperance he also devoted many of his designs, especially the tragic and powerful series of *The Bottle* (1847), which, reproduced by glyptography, attained an immense circulation. He died 1st February 1878. There are excellent collections of his works in the print-room, British Museum; the Royal Aquarium, Westminster; and the South Kensington Museum. The last named, presented in 1884 by the artist's widow, numbers 3481 items. See G. W. Reid's *Catalogue* (3 vols. 1871), and *Jerrold's Life* (2 vols. 2d ed. 1883).

Cruiser, an armed ship, employed chiefly to cruise about protecting the commerce of the country, or capturing enemies' ships. See PRIVATEER.

Cruithne. See PICTS.

Crusades is the name given to the religious wars carried on during the middle ages between the Christian nations of the West and the Mohammedans. In time, however, the name came to be applied to any military expedition against heretics or enemies of the pope. The first of the regular crusades was undertaken simply to vindicate the right of Christian pilgrims to visit the Holy Sepulchre. On the conquest of Palestine, however, the object of the crusades changed, or at least enlarged, and the efforts of the subsequent crusaders were directed to the recovery of the whole land from the Saracens, who had repossessed themselves of it. From an early period in the history of the church, it was considered a pious act to make a pilgrimage to the Holy Sepulchre, and to visit the various spots which the Saviour had consecrated by his presence. When Palestine was conquered by the Arabs in the 7th century, that fierce but generous people respected the religious spirit of the pilgrims, and allowed them to build a church and a hospital in Jerusalem. Under the Fatimides of Egypt, who conquered Syria about 980 A.D., the position both of the native Christian residents and of the pilgrims became less favourable; but the subjugation of the country in 1065 by brutal hordes of Seljuk Turks from the Caucasus rendered it intolerable. These barbarians, but recently converted to Mohammedanism, were nearly as ignorant of the Koran as of the Scriptures. They hardly knew their fellow-religionists, and are said to have wreaked their vengeance on the Mussulmans of Syria as well as on the Christians. The news of their atrocities produced a deep sensation over the whole of Christendom. The first to take alarm were, naturally enough, the Byzantine monarchs. In 1073 the Greek emperor, Manuel VII., sent to supplicate the assistance of the great Pope Gregory VII. against the Turks, accompanying his petition with many expressions of profound respect for His Holiness and the Latin Church. Gregory—who beheld in the supplication of Manuel a grand opportunity for realising the Catholic unity of Christendom—cordially responded; but circumstances prevented him from ever carrying the vast designs which he entertained into execution, and the idea of a crusade died gradually away. It was, however,

revived by his successor, Urban II., an able and humane man, whose sympathies were kindled by the burning zeal of Peter the Hermit, a native of Amiens, in France, who had made a pilgrimage to the Holy Land, and witnessed the cruelties perpetrated by the Turks. He was now traversing Europe, preaching everywhere to crowds in the open air, and producing the most extraordinary enthusiasm by his impassioned descriptions of how pilgrims were murdered, robbed, or beaten; how shrines and holy places were desecrated; and how nothing but greed restrained the ruffian Turks (who made the Christians pay heavy taxes for their visits to Jerusalem) from destroying the Holy Sepulchre, and extirpating every vestige of Christianity in the land. As soon as the feelings of Europe had been sufficiently heated, Urban openly took up the question. Two councils were held in 1095. At the second, held at Clermont, in France, a crusade was definitely resolved on. The pope himself delivered a stirring address to a vast multitude of clergy and laymen, and as he proceeded, the pent-up emotions of the crowd burst forth, and cries of *Deus vult* ('God wills it') rose simultaneously from the whole audience. 'This tumultuous cry,' says Hallam, 'which broke from the heart and lips of the assembly at Clermont, affords at once the most obvious and most certain explanation of the leading principle of the crusades.' These words, *Deus vult*, by the injunction of Urban, were made the war-cry of the enterprise, and every one that embarked in it wore, as a badge, the sign of the cross; hence the name *Crusade* (Fr. *croisade*, from Lat. *cruz*, 'a cross').

First Crusade.—From all parts of Europe thousands upon thousands hurried at the summons of the pope to engage in the holy war. 'The most distant islands and savage countries,' says William of Malmesbury, 'were inspired with this ardent passion. The Welshman left his hunting, the Scotchman his fellowship with vermin, the Dane his drinking-party, the Norwegian his raw fish.' It is said that in the spring of 1096 not less than 6,000,000 souls were in motion towards Palestine. This, however, must be a huge exaggeration. What we do know positively is, that previous to the setting out of the great hosts of European chivalry, four armies—if disorderly multitudes deserve that name—amounting in all to 275,000 persons, had departed for Palestine. The first consisted of 20,000 foot, and was commanded by a Burgundian gentleman, Walter the Penniless. It marched through Hungary, but was cut to pieces by the natives of Bulgaria, only a few, among whom was Walter himself, escaping to Constantinople. The second, consisting of 40,000 men, women, and children, was led by Peter the Hermit. It followed the same route as its predecessor, and reached Constantinople greatly reduced in numbers. Here the two united, crossed the Bosphorus, and were utterly defeated by the Turks at Nicaea, the capital of Bithynia. A third expedition of a similar kind, composed of 15,000 Germans, led by a priest named Gottschalk, was dispersed with terrible slaughter in Hungary; which also proved the grave of the fourth, a horde consisting of about 200,000 wretches from France, England, Flanders, and Lorraine, who had swept along through Germany, committing horrible ravages, especially against the Jews, whom they murdered without mercy. Now, however, the real crusaders made their appearance: the gentry, the yeomanry, and the serfs of feudal Europe, under chiefs of the first rank and renown. In this, the most successful of the crusades, neither the emperor nor any of the kings of the West participated; and to this circumstance was doubtless due its more fortunate termination. Six armies appeared in the field, marching separately, and at considerable

intervals of time. Their respective leaders were Godfrey of Bouillon, Duke of Lorraine; Hugh the Great, Count of Vermandois, and brother of Philippe, king of France; Robert Curthose, Duke of Normandy, the son of William the Conqueror; Count Robert of Flanders; Bohemond, Prince of Tarentum, son of the famous Guiscard, under whom was Tancred, the favourite hero of all the historians of the crusade; and lastly, Count Raymond of Toulouse. The place of rendezvous was Constantinople. The Greek emperor, Alexius, afraid that so magnificent a host—there were in all not less than 600,000 men, exclusive of women and priests—might be induced to conquer lands for themselves, cajoled all the leaders, excepting Tancred and Count Raymond, into solemnly acknowledging themselves his liegemen as long as they remained in his territory. After some time spent in feasting, the crusaders crossed into Asia Minor accompanied by the unfortunate Peter the Hermit. Here their first step was the siege and capture of Nicaea, the capital of Sultan Soliman, 24th June 1097. This monarch was also defeated by Bohemond, Tancred, and Godfrey, at Dorylaeum. Baldwin, brother of Godfrey, now crossed into Mesopotamia, where he obtained the principality of Edessa. After some time, the crusaders reached Syria, and laid siege to Antioch. For seven months the city held out, and the ranks of the besiegers were fearfully thinned by famine and disease. Many even brave warriors lost heart, and began to desert. Melancholy to relate, among the deserters was the poor enthusiast who had inspired the enterprise. Peter was actually several miles on his way home when he was overtaken by the soldiers of Tancred, and brought back to undergo a public reprimand. At length, on the 3d of June 1098, Antioch was taken, and the inhabitants were massacred by the infuriated crusaders, who were in their turn besieged by an army of 200,000 Mohammedans sent by the Persian sultan. Once more famine and pestilence did their deadly work. Multitudes also deserted, and escaping over the walls, carried the news of the sad condition of the Christians back to Europe. But again victory crowned the efforts of the besieged. On the 28th June 1098 the Mohammedans were utterly routed, and the way to Jerusalem opened. It was on a bright summer morning (1099) that 40,000 crusaders, the miserable remnant of that vast array which two years before had laid siege to Nicaea, obtained their first glimpse of Jerusalem. On the 15th of July, after a siege of rather more than five weeks, the grand object of the expedition was realised. Jerusalem was delivered from the hands of the infidel. As on the occasion of all the triumphs of these first crusaders, a horrible massacre ensued. Religious enthusiasm, evoking the intensest and most strangely mingled passions, naturally led to these excesses on the part of men reared in the fiercest times of feudalism. Eight days after the capture of the city, Godfrey of Bouillon was unanimously elected king of Jerusalem. His kingdom, at first comprising little more than the mere city of Jerusalem, was gradually extended by conquest until it included the whole of Palestine. A language resembling Norman French was established, a code of feudal laws drawn up—Jerusalem was erected into a patriarchate, and Bethlehem into a bishopric. The best part of Asia Minor was restored to the Greek empire, while Bohemond became Prince of Antioch. For nearly fifty years, the three Latin principalities or kingdoms of the East—Edessa, Antioch, and Jerusalem—not only maintained themselves against the attacks of the Mohammedans of Egypt and Syria, but greatly increased in size, power, and wealth. At Jeru-

salem were founded the two famous orders of the Knights Hospitallers of St John and the Knights Templars.

Second Crusade.—In 1144 the principality of Edessa was conquered by the Emir of Mosul, and the Christians slaughtered. His son, Nouredin, advanced to destroy the Latin kingdoms of Syria and Palestine. Europe once more trembled with excitement. A second crusade was preached by the famous St Bernard, abbot of Clairvaux, in Champagne; and early in 1147 two enormous armies, under the command of Louis VII., king of France, and Conrad III., emperor of Germany, marched for the Holy Land. Their united numbers were estimated at 1,200,000 fighting-men. The expedition, nevertheless, proved a total failure. The Greek emperor, Manuel Comnenus, was hostile; and through the treachery of his emissaries, the army of Conrad was all but destroyed by the Turks near Iconium, while that of Louis was wrecked in the defiles of the Pisidian Mountains. After a vain attempt to reduce Damascus, the relics of this mighty host returned to Europe.

Third Crusade.—The death-blow, however, to the kingdom of Jerusalem, and the power of the crusaders, was given, not by Nouredin, but by Salah-Eddin, commonly called Saladin, a young Kurdish chief, who had made himself sultan of Egypt, and who aspired to the suzerainty of the Mohammedan world. He invaded Palestine, took town after town, and finally, in October 1187, compelled Jerusalem itself to capitulate, after a siege of fourteen days. The news of this led to a third crusade, the chiefs of which were Frederick I. (Barbarossa), emperor of Germany; Philippe Auguste, king of France, and Richard Cœur-de-Lion, king of England. Barbarossa took the field first in the spring of 1189, but lost his life by fever caught from bathing in the Orontes. His army, much reduced, joined the forces of the other two monarchs before Acre, which important city was immediately besieged. In vain did Saladin attempt to relieve the defenders; and after a beleaguering of twenty-three months, the place surrendered. But the crusaders were not united among themselves. Philippe soon after returned to France; and Richard, after accomplishing prodigies of valour, which excited the admiration of the Saracens, concluded a treaty with Saladin, by which 'the people of the West were to be at liberty to make pilgrimages to Jerusalem, exempt from the taxes which the Saracen princes had in former times imposed.' This, as has been previously noticed, was all that had been claimed by the first crusaders. On the 25th of October 1192, Richard set sail for Europe.

Fourth Crusade.—Crusading unfortunately now became a constituent of the papal policy; and in 1203 a fourth expedition was determined upon by Pope Innocent III., although the condition of the Christians was by no means such as to call for it. It assembled at Venice; but how entirely secular crusading had become, will be seen from the fact that the army never went to Palestine at all, but preferred to take possession of the Byzantine empire. The leader of this host of *pseudo-crusaders*, Baldwin, Count of Flanders, was seated on the throne of the East in 1204, and thus founded the Latin empire of Constantinople, which lasted for fifty-six years. Nothing was achieved in this crusade for the recovery of Jerusalem, but Innocent had his reward in the temporary supremacy of the papal see over the Eastern Church.

Fifth Crusade.—This was commanded by Frederick II., emperor of Germany. It began in 1228, and terminated in a treaty between that monarch and the sultan of Egypt, by which Jerusalem (with

the exception of the Mosque of Omar), Jaffa, Beth-lehem, and Nazareth were ceded to Frederick, who, after being crowned king of Jerusalem, returned to Europe, leaving his new possessions in a state of tranquillity. Frederick, however, who had been excommunicated by Gregory IX. for his tardiness in embarking in this crusade, was denounced in the most violent language by the same pope for having thus made terms with the infidel.

Sixth Crusade.—In 1244 the Khorasmians, driven from Tartary by Genghis Khan, burst into Syria, and made themselves masters of Jerusalem. This was made, by Pope Innocent IV., the occasion for another crusade; and in 1249 Louis IX. (St Louis) of France headed an expedition against Egypt, which was now regarded as the key of the Holy Land. The expedition was an utter failure. Louis was defeated and taken prisoner by the sultan, and obtained his liberty only on the payment of a heavy ransom.

Seventh Crusade.—This also was primarily undertaken by St Louis, but he having died at Tunis (where he had gone in the hope of baptising its king) in 1270, on his way to Palestine, Prince Edward of England, afterwards Edward I., who had originally intended to place himself under the command of St Louis, marched direct for Palestine, where his rank and reputation in arms gathered round him all who were willing to fight for the cross. Nothing of consequence, however, was accomplished; and Edward soon returned to England, the last of the crusaders. Acre, Antioch, and Tripoli still continued in the possession of the Christians, and were defended for some time by the Templars and other military knights; but in 1291 Acre capitulated, the other towns soon followed its example, and the knights were glad to quit the country, and disperse themselves over Europe in quest of new employment, leaving Palestine in the undisturbed possession of the Saracens.

Besides the great expeditions above enumerated, there were many others on a lesser scale. These, however, from the unimportance of their results, and the limited numbers engaged in them, do not call for special mention. Of the pseudo-crusades, three deserve notice for the important results that followed from them. Firstly, in 1209, there was that against the Albigenses (q.v.). Secondly, on the principle that it was binding on the servants of the church to do battle with all outside its pale, in 1230 the Teutonic knights were called on by Gregory IX. to undertake a crusade against the heathen Prussians on the shores of the Baltic. The result was the complete subjugation of the Prussians, and the establishment in their country of the Teutonic military order till its extinction at the battle of Tannenberg in 1410. Thirdly, in 1262 Urban IV., jealous of the growing power of Manfred, king of Sicily, son of the Emperor Frederick II., offered Manfred's crown to Charles of Anjou, brother of St Louis of France, and gave to this dispossession the name of a crusade. A protracted war ensued, which resulted in the House of Anjou gaining the kingdom of Naples, and the House of Aragon the kingdom of Sicily. The terrible wars of the 16th century between France and Spain for supremacy in Italy were the direct consequence of this pseudo-crusade.

Effects of the Crusades.—While we cannot help deploring the enormous expenditure of human life which the crusades occasioned, it is impossible to overlook the fact that they indirectly exercised a most beneficial influence on modern society. They secured for humanity certain advantages which it is difficult to see could have been otherwise obtained. Guizot, in his *Lectures on European Civilisation*, endeavoured to show their design and function in the destinies of Christendom. 'To the

first chroniclers,' he says, 'and consequently to the first crusaders, of whom they are but the expression. Mohammedans are objects only of hatred: it is evident that those who speak of them do not know them. The historians of the later crusades speak quite differently: it is clear that they look upon them no longer as monsters; that they have to a certain extent entered into their ideas; that they have lived with them; and that relations, and even a sort of sympathy, have been established between them.' Thus the minds of both, but particularly of the crusaders, were partly delivered from those prejudices which are the offspring of ignorance. 'A step was taken towards the enfranchisement of the human mind.' Secondly, the crusaders were brought into contact with two civilisations, richer and more advanced than their own—the Greek and the Saracenic; and it is beyond all question that they were mightily struck with the wealth and comparative refinement of the East. Thirdly, the close relationship between the chief laymen of the West and the church, occasioned by the crusades, enabled the former 'to inspect more narrowly the policy and motives of the papal court.' The result was very disastrous to that spirit of veneration and belief on which the church lives, and in many cases an extraordinary freedom of judgment and hardihood of opinion were induced—such as Europe had never before dreamed of. The immediate results of the crusades, however, went altogether to strengthen the power of the church. Through their means the popes found an easy method of ridding themselves of refractory monarchs; and by the exorbitant taxes levied in the name of the cross they practically rendered all the kingdoms of the West their tributaries. Fourthly, great social changes were brought about. A commerce between the East and West sprang up, and towns—the early homes of liberty in Europe—began to grow great and powerful. The crusades, indeed, 'gave maritime commerce the strongest impulse it had ever received.'

Paris, 1841-86). Reference may also be made to Scott's *Talisman and Count Robert of Paris*.

Crusca, ACCADEMIA DELLA. See ACADEMY, DELLA CRUSCANS.

Crusenstolpe, MAGNUS JAKOB, an eminent Swedish political writer, was born at Jönköping, 11th March 1795. At first a lawyer, he afterwards settled at Stockholm as a publicist and man of letters. He wrote novels, elaborate historical works, pamphlets, and contributed to the newspapers. His *Ställningar och Förhållanden*, carried on from 1838 till 1865, applied vigorous and unsparring criticism to the questions and persons of the day. His bitter opposition to government cost him three years' imprisonment (1838-41). He died 18th January 1865.

Crustacea, a large and important class of Arthropod animals, including crabs, lobsters, shrimps, sand-hoppers, wood-lice, water-fleas, barnacles, acorn-shells, &c. The class contains such variety of structure that general characters are hard to find. They are almost all aquatic, but a few (e.g. wood-lice and land-crabs) are terrestrial. The majority are marine, but great numbers inhabit fresh water. The form of the body is very variable, as may be seen by contrasting crab and barnacle. A head with five pairs of appendages, a limb-bearing thorax more or less united to the former, and a segmented abdomen with or without

limbs, are very generally distinguishable. The segmentation is never developed in the Ostracod water-fleas, and is often lost in degenerate forms. By the development of shields (Apus), bivalve shells (water-fleas), and mantles (Cirripedes); the real form is often obscured. As to appendages, the head usually bears two pairs of antennae; a pair of mandibles, and two pairs of maxillae; the thorax is always limb-bearing except in utter degeneracy; and the abdomen of the majority also carries appendages. The typical form of limb, on which so many changes are rung, consists of a basal piece and two more or less jointed forks. The cuticle varies greatly in degree of firmness, but is always chitinous (see CHITIN) and often much calcified. Glands open on various parts of the surface, and may be of use for preliminary digestion, for egg-attachment, for mooring the animal, &c. The colouring of the body is often very brilliant and beautiful (see PIGMENT). It is sometimes like that of the surroundings, and is occasionally associated with sexuality. The power of colour-change is also not uncommon. Sapphirina is said to rival the humming-bird in its splendour. While the nervous system in general retains the Arthropod characteristics, the ventral ganglia are often concentrated (as in crabs). The majority possess compound eyes, which in one large division are stalked. Eyes are absent in some subterranean forms, and are lost during the development of Cirripedes (q.v.) and many parasites. In the Euphausiidae there are very numerous eye-like structures or luminous organs over the body. Smelling hairs usually occur on the first antennae, and auditory hairs have been frequently observed, usually more or less inclosed in sacs. The alimentary system, which consists of fore, mid, and hind gut, is usually simple, except as regards the hard masticating parts often developed on the cuticle of the anterior portion. In some parasitic forms the entire system degenerates. The body-cavity is usually a good deal filled up by the muscles and viscera; it contains the blood-fluid, which is occasionally faintly coloured with hæmoglobin, tetroneurhythm, and other pigments, and includes amœboid elements. A heart is usually present in the thoracic region, and is often inclosed in a special part of the body-cavity—the pericardium. In higher forms the blood passes by distinct arteries to the bodies, is gathered up in venous spaces and sinuses, is purified in the gills, and returns to the pericardial sac and heart. The respiratory system is typically represented by distinct gills variously attached; in many cases water flows in and out at the anus, and probably effects an anal respiration; in many lower forms the blood is simply purified by being exposed under the skin. The excretory system is never very marked. The green glands of higher forms, the shell-glands of Phyllopods and Copepods, and certain other structures, are excretory. The reproductive system presents many variations. The sexes are usually separate, but most Cirripedes are hermaphrodite. 'In the Cymothoidae (Isopoda) the sexual organ of the young animal is male—of the old, female—in function.' The glands are usually thoracic, and the ducts double. Some of the appendages are often modified for copulation or egg-retaining. The spermatozoa are peculiar in being usually non-motile. The eggs are in most cases carried about by the female, but are occasionally laid on water-plants, &c., or in the water. According to Bates, *Podocerus capillatus* builds a nest of interlaced seaweed. Parthenogenesis (q.v.) has been observed in some of the lower forms. 'Complemental' males occur among the hermaphrodite Barnacles and Acorn-shells (q.v.).

Life-history.—The development of Crustaceans is usually indirect—that is to say, the newly-

hatched young is unlike, often very unlike, its parent. Even when there is no metamorphosis after hatching, traces of transformation, as opposed to continuous development, are sometimes to be detected in the earlier history while the embryo is still within the egg-case. (a) The crayfish (*Astacus*) has a very much abbreviated life-history, for the newly-hatched form is almost quite like the adult. (b) The newly-hatched lobster (*Homarus*), however, begins life a little further back, in what is known as the *Mysis* stage, in which the thorax bears two-branched swimming appendages. (c) Most other higher Crustaceans (e.g. crabs) begin at a still lower level, in what is called the *Zoea* stage, with a short unjointed thorax and a segmented abdomen without limbs. (d) The

Development of a Prawn (*Penaeus*):
a, Nauplius; b, Zoea; c, Mysis; d, adult.

Decapod *Penaeus*, a shrimp-like creature, has its life-history still more drawn out. It quits the egg as a *Nauplius*, an unsegmented larva with three pairs of appendages, the first unforked, the other two pairs double-branched. These correspond to the first three appendages of the adult. The median eye is also a distinctive feature in the *Nauplius* larva. The *Penaeus Nauplius* has with successive moults first to become a *Zoea*, and then a *Mysis*, and then an adult. It is as a *Nauplius* that the majority of lower Crustaceans leave the egg, but then they do not climb so high. To understand the circuitous life-history of a form like *Penaeus*, we have to note that it begins in the *Nauplius* stage, at the level of the lowest Crustaceans, and gradually climbs through a series of higher and higher stages, each of which is represented permanently by some division of Crustaceans which have not risen higher. If the various grades from *Nauplius* up to Decapod adult represent successive historic levels, now exemplified in the classification of Crustaceans by those which were left behind at each lift, what the *Penaeus* does is to recapitulate in its individual life-history the historic evolution of the class. This idea has been beautifully applied to Crustaceans in Fritz Müller's *Facts for Darwin*. The various grades of *Nauplius*, *Zoea*, *Mysis*, and adult *Penaeus* (overlooking intermediate ones) may be compared to stations which mark the gradual extension of the Crustacean line of advance. *Penaeus* has to travel along the rails laid down by the ancestral history, and has to stop for variable periods at the successive stations between the starting-point and the terminus. Crabs skip over the *Nauplius* station, and like most other Decapods

start at the *Zoea* point; lobsters abbreviate still further, and begin as *Mysis* forms; the crayfish has found the shortest cut of all. Some of the lower Crustaceans never get far past the *Nauplius* stage, while others remain practically on the *Zoea* grade. The life-histories of Crustaceans vividly illustrate how the individual life-history is a rehearsal of the historic evolution of the kind, or more technically, how ontogeny recapitulates phylogeny.

Habit of Life.—The acorn-shells fastened to the rocks, wafting in their food by their curled feet; the barnacles moored to floating logs and ship-bottoms; such extremes of parasitism as are illustrated by *Sacculina* on hermit-crabs; the hermit-crabs themselves, stealing the shells of *Gasteropoda*, or entering into partnership with sea-anemones; the thousand minute and active water-fleas; the wood-lice, quite terrestrial; the brine-shrimps in the salt-pools; the fresh-water crayfish; the giant marine lobsters; the land-crabs, habituated to inland life, sufficiently suggest how varied are the habits of Crustaceans. Some Crustaceans form masking shelters for themselves out of Tunicates, or get covered over by a concealing growth of seaweed, sponge, hydroids, &c. A few forms are known to make a stridulating noise. The general intelligence of the class is probably considerable (see *CRAB*). On the whole the members of this class are active animals, but on each side of the medium activity of the majority there are extremes. Thus, not a few active marine forms are phosphorescent, while parasitism (to the extent of some 700 species) occurs in most of the subdivisions. Many of the parasites are very striking in the contrast between the free-swimming young and the *ne plus ultra* of degeneracy in the adults (see *DEGENERATION*, *PARASITISM*). Some of the interesting cases of Commensalism (q.v.) have been referred to under that title; while some of the external parasites show in the castration, &c. which they effect on their hosts, how real in such cases is the direct influence of the animate Environment (q.v.). The diet of Crustaceans is very varied; the majority are carnivorous and aggressive; many feed on dead creatures and organic debris in the water; others depend largely upon plants. They often lose limbs in fighting or otherwise, and have the power of replacing what they have lost.

Classification (after Claus).—(A) *Entomostraca*. Lower forms, small, simple, with variable number of rings and appendages, with not more than three appendages concerned in mastication, usually leaving the egg as a nauplius. (1) *Phyllopoda*: (a) *Branchiopoda*—e.g. Brine-shrimps (q.v.), *Apus*, *Estheria*, &c.; (b) *Cladocera*—the common 'water-flea' *Daphnia*, *Moina*, &c. (2) *Ostracoda*—common *Cypris* (q.v.), *Cypridina*. (3) *Copepoda*—common *Cyclops* (q.v.), *Lernaea*, &c. (4) *Cirripedia*—Acorn-shells, Barnacles (q.v.), *Sacculina*, &c.—(B) *Malacostraca*. Higher, larger forms, with nineteen segments, with more than three appendages concerned in mastication, usually quitting the egg at a higher level than the *Nauplius*: (1) *Leptostraca*, *Nebalia*, a primitive form with bivalve shell; (2) *Arthrostraca*, with free thorax, and no cephalothoracic shield, eyes sessile: (a) *Amphipoda*—Sand-hoppers (q.v.), *Caprella*, &c.; (b) *Isopoda*—Wood-lice (q.v.), *Asellus*, *Tanais*, &c. (3) *Thoracostraca*, with all or part of thorax fused to head, and with a cephalothoracic shield, eyes mostly stalked: (a) *Cumacea*, sessile-eyed—*Cuma*; (b) *Stomatopoda*, with gills on abdominal feet—*Squilla*; (c) *Podophthalmata*, with stalked eyes and large shield: (i) *Schizopoda*, with eight pairs of double thoracic feet—*Mysis*; (ii) *Decapoda*, with thorax fused to head, and last five thoracic feet not double; long-tailed

(Macrura)—e.g. Crayfish (q.v.), Lobster; short-tailed (Brachyura), Crabs.

Distribution in Space and Time.—(a) Deep-sea forms are very abundant, and often remarkable 'for their colossal size, their bizarre forms, and brilliant red colouring.' Blind species are known to occur in the depths, and others are brilliantly phosphorescent. (b) Pelagic surface Crustaceans (especially Schizopods and Entomostraca) are very abundant, and often form a large part of the food of fishes. They are often beautifully transparent, and hardly to be seen in the water. Less frequently they are brilliantly coloured (as in Sapphirina) or phosphorescent. Some of them are remarkable for their large eyes. One Amphipod Crustacean presents a curious mimicry of a Medusoid form. Decapods are most abundant in the warmer waters. (c) Crustaceans form an important part of the relatively sparse and uniform fauna of lakes. They occur both on the surface and at the bottom, the latter being generally more sluggish. The surface forms, at any rate, are usually perfectly transparent, with the exception of the eye. (d) The catalogue of terrestrial Crustaceans, which includes species of Amphipods, Isopods, and Decapods, is relatively a very short one.

The Crustacea date back to Cambrian times, but the highest forms (Decapods) were not firmly established till the Tertiary period. Some 800 fossil species, as against over 5000 living forms, are known. Some of the genera—e.g. *Estheria*—from the Devonian, are marvellously persistent, and survive from ancient epochs as still very successful and widely distributed forms. The Trilobites (q.v.) are not now regarded as true Crustaceans. (For distribution, see Heilprin, *Inter. Sc. Series*, 1887.)

Pedigree.—It is usually believed that Crustacea are descended from a primitive Phyllopod-like ancestor, and this from a segmented worm-type. The very constant occurrence of a Nauplius larva has led zoologists to regard it as representing a remote ancestor. The lines of differentiation chiefly consisted in the development and manifold modification of the fundamentally similar appendages, and in the perfecting of the exoskeleton as a base for muscular attachment. (See Herdman's *Classification of Animals*, Lond. 1885.)

Economic Importance.—Crabs, lobsters, crayfish, shrimps, prawns, &c. form part of our food-supply. Others are indirectly useful as important parts of the food of herrings and other fishes. Many are doubtless useful in purifying the water from organic debris, while others are the hosts of important parasites—e.g. the Cyclops species, which contains *Draunculus medinensis*.

See ACORN-SHELLS, BARNACLE, BRINE-SHRIMP, CIRRIPIEDIA, COPEPOD, CRAB, CRAYFISH, CYPRIS, CYCLOPS, LOBSTER, PRAWN, SHRIMP, WATER-FLEA, &c.; also COMMENSALISM, PARASITISM, PARTHENOGENESIS, &c., and references under above articles. For further details, consult general text-books of Brooks (Boston, 1882), Claus, Gegenbaur, Huxley, Rolleston and Hatcher Jackson; also Baird, *British Entomostraca* (Ray Soc. 1850); Balfour's *Embryology*; Bell, *British Stalk-eyed Crustacea* (Lond. 1856); Challenger Reports (several); Claus, *Genealogy of Crustacea* (1876); Dana, *Crustacea of U.S. Exploring Expedition* (Phila. 1852); Gerstaecker in Bronn's *Thierreich*; Huxley's *Crayfish* (1881); Milne-Edwards, *Histoire Naturelle des Crustacés* (Paris, 1834-40); the Monographs of the Naples Station (several); F. Müller, *Facts for Darwin* (1869); Sara, *Fresh-water Crustacea of Norway* (Christiania, 1867); Spence Bate and Westwood, *British Sessile-eyed Crustacea* (Lond. 1863-68).

Crutched Friars, an order of friars, carrying in their hand a staff, on the top of which was a cross, received the name of *Croisiers* (Fr. *croix*, 'cross'), corrupted into *Crouched* or *Crutched*

Friars. They came to England in the 13th century, and had monasteries in London (which still gives name to a street), Oxford, and Reigate.

Cruveilhier, JEAN, physician, born at Limoges in 1791, became professor of Pathology at Montpellier in 1824, and of Pathological Anatomy in Paris in 1836. Besides his great work, *Anatomie Pathologique du Corps Humain* (2 vols. 1828-42), he published several other works on anatomy, which were for many years the most valuable French contributions to their subject, and also a *Life of Dupuytren* (1840). He died 6th March 1874.

Crwth (pronounce the *w* as French *u*), an old Welsh stringed instrument. Four of its six strings were played with a bow, the other two being twitched by the thumb.

Cryolite, a mineral which exists in great abundance on the coast of Greenland. It consists mainly of a fluoride of aluminium in combination with Fluoride of Sodium, $6\text{NaF} \cdot \text{AlF}_3$. The metal Aluminium (q.v.) was formerly largely obtained from it, but it is now most important as a source of alum and of soda bicarbonate; much of it, also, is melted and made into a kind of glass.

Cryophorus (Gr. *kryos*, 'cold,' and *phero*, 'I carry') is an instrument consisting of a glass tube with a bulb at both ends, used for showing the diminution of temperature in water by evaporation. In constructing it the whole of the air is extracted, leaving practically a vacuum inside. A little water is present in one of the bulbs, and when the second bulb, containing only water-vapour, is placed in a freezing mixture, the vapour condenses, which causes more vapour to rise from the water in the first bulb. The result of this vaporation from the first bulb is the abstraction of much heat, and ultimately the remaining water passes into a frozen state.

Crypt (Gr. *krypto*, 'I hide'). In the early days of persecution the Christians were accustomed for security to worship in the catacombs or crypts where they buried their dead (see CATACOMBS). When persecution ceased, this custom led to the erection of churches over the graves of martyrs and saints; but at a later date the bodies of the saints were transferred to chambers, constructed to resemble the catacombs, under the sanctuary or altar of the new churches, in order to add to their sanctity. These crypts and their sacred shrines were visited by numerous pilgrims, and were frequently constructed for the accommodation of the devotees, of sufficient size to admit a number at a time, who descended by one stair, and ascended by another. In other cases the crypts were so placed that the shrine of the saint could be seen from the aisles of the choir, the floor of which was necessarily raised considerably above the level of the nave. Crypts of these kinds were usual in the early centuries, and many examples of them have been preserved in Italy and France, even where the churches over them have been rebuilt. The crypt of the Circular church of St Bénigne at Dijon was one of the largest. There a great circular aperture in the centre of the floor of the upper church enabled a very large congregation of pilgrims, including those in the crypt, to see the shrine of the saint, and witness any ceremony taking place there.

After the 13th century crypts were not so much in use. The great cathedrals were regarded as much in the light of civil as of ecclesiastical edifices, and the floor of the choir was brought down to the level of the rest of the building. It sometimes happened that owing to the slope of the site considerable underbuilding was required under the choir, in which case an under church was constructed, which was called by the old name of the

crypt, and was generally used for sepulchral purposes. The crypt of Canterbury is one of the finest of this kind. The crypt of Glasgow Cathedral is

Crypt, Canterbury Cathedral.

also a very beautiful example, the vaulting over the shrine of St Mungo being pointed out by Sir Gilbert Scott in his lectures as one of the best specimens of its class.

Cryptogamia. This term was introduced by Linnaeus as the twenty-fourth and last class of his system of classification, and broadly with its present contents. The name, however (Gr. *kryptos*, 'concealed,' and *gamos*, 'marriage'), in opposition to flowering plants (*Phanerogamia*, q.v.), records its donor's well-founded expectation that sexual reproduction would one day be discovered. Jussieu proposed to distinguish them as *Acotyledones* from monocotyledons and dicotyledons; but the term has necessarily lapsed for many reasons. De Candolle distinguished them into two great groups, *Cellulares* and *Vasculares*; while Endlicher's separation of the vegetable kingdom into *Thallophytes* and *Cormophytes* still further recognised their vast morphological range. Armed with the microscope more recent investigators have determined the life-history and mode of reproduction of all the leading types, so not only amply confirming the hypothesis of Linnaeus, or even still further increasing their morphological importance as compared with *Phanerogams*, but entirely revolutionising our interpretation of the flowering plants themselves, since leading us to view them as more profoundly cryptogamic than the cryptogams. The separate groups of cryptogamic plants are outlined in the articles *ALGÆ*, *SEAWEEDS*, *BACTERIA*, *FUNGI*, *LICHENS*, *MOSESSES*, *FERNS*, *RHIZOCARPS*, *EQUISETUM*, *LYCOPodium*, *SELAGINELLA*; while their relation to higher plants is explained under *PHANEROGAMIA*, *FLOWER*, *GYMNOSPERMS*.

Cryptography, the art of secret writing, also called *Writing in Cipher*, *Hieroglyphic Writing*, *Secret Writing*, *Steganography*, *Polygraphy*, has been in use from an early date in correspondence between diplomatists and others engaged in important affairs requiring secrecy. Every government used to employ its staff of decipherers, who availed themselves of extraordinary means for interpreting despatches which (fairly or unfairly) came into their possession. The cipherers and the decipherers waged a constant struggle to outwit each other; the one by constructing new difficulties; the other by conquering the difficulties as soon as constructed. How often we hear of a courier being murdered and his despatches carried off! And without the

key to decipher letters so written, to what purpose would they be intercepted by such a deed? In these modern times, however, there has been so great an improvement in the morals of governments that the custom of killing foreign-office messengers for the sake of their despatch-bags is entirely obsolete in diplomacy, and statesmen have ceased to pillage post-offices or rifle portmanteaus for cryptographic messages.

Most of the odd knacks, contrivances, decoys, blinds, now employed by cryptographers were to some extent known to and employed by the ancients. Substituting points for vowels; arranging threads, knots, or ink-spots at determinate distances; substituting one letter for another; inventing new arbitrary characters for whole words or even sentences—now made use of extensively in telegraph codes; abbreviating words in their prefixes and affixes; writing a long sentence of nonsense, with a clue to find the words which gave the proper sense—all were brought into requisition. Perhaps the most amusing of all cryptography was the one mentioned by Herodotus. Histieus, a Greek at the Persian court, being desirous of sending a secret message to Aristagoras at Miletus, selected a slave who was afflicted with bad eyes, and shaved his head, pretending that it was necessary for his recovery. In performing this, Histieus imprinted his secret intention in legible characters on the man's head, and kept him in close confinement till his hair grew again, when he sent him to Aristagoras for a perfect cure. Aristagoras repeated the shaving, read the writing underneath, and thus obtained the desired information by means of the unconscious messenger.

One of the simplest methods of cryptography is to use instead of each letter of the alphabet a certain other letter at a regular interval in advance. Such was a mode of secret writing adopted by Julius Cæsar. As a variety of this plan, the alphabet is used invertedly, *z* for *a*, *y* for *b*, *x* for *c*, and so on; or, while the first seven letters are represented by the second seven, the next six may be represented by the last six. And many other variations may be adopted. But the decipherment of such messages is naturally not difficult, and with a little consideration of the peculiarities of the English language, all the ups and downs of many an interesting love story related in cipher in the columns of the *Times* can be followed from start to finish with comparative ease. It is known that *e* is the most frequent letter; that *the* is the commonest word; that *ea* and *ou* are the double vowels which most frequently occur; that the consonants most common at the ends of words are *r*, *s*, and *t*, &c. We also know that a word of a single letter must be either the pronoun *I*, or the vowels *a* or *O*; that *an*, *at*, *on*, *to*, *of*, and *in* are the most common words of two letters; that *the* and *and* are the most frequent words in three letters; that the most usual doubled letters are *ce*, *oo*, *ll*, *ss*, *ff*; that double vowels are mostly followed by *l*, *m*, *n*, *r*; that the letter *a* begins three two-letter words in very extensive use—*an*, *as*, *at*; that the letter *o* begins or ends eight two-letter words in very common use—*do*, *go*, *no*, *so*, *to*, *of*, *on*, *or*; that more words in a sentence of average English begin with *t* than with any other letter; that in about three-fourths of all the words in a sentence, either the first or the second letter is a vowel; that among consonants, *d* and *h* are most largely used, after which come *n*, *s*, *r*, *t*; that the letter *q* is always followed by *u*; that no English word of two letters or more ends with *i*. All these considerations will guide us to the solution of any simple cipher, enabling a skilful decipherer to read almost any ordinary piece of cryptographic writing in a very short time.

In British history, cryptography has at no time been in greater requisition than during the Civil War, when Charles I. invented some abstruse ciphers which would have puzzled modern experts in the art. His celebrated letter to the Earl of Glamorgan, in which he made some compromising concessions to the Catholics of Ireland, was composed in an alphabet of twenty-four short strokes variously situated upon a line (see OGHAMS). Other letters by the same monarch are to appearance a mere series of numbers of two or three figures divided by semicolons. In such cases it was necessary that the two parties engaging in the correspondence should have previously concerted what words each number was to represent.

In the reign of William III. the Jacobites invented many curious ciphers to enable them to communicate with their exiled king. All the Jacobite clubs had distinct methods of their own—their great aim being to write in such a manner that the very ciphers themselves should pass through their enemies' hands without suspicion. This they accomplished by means of sympathetic inks. A favourite Jacobite cipher was the use of parables, conveying, by means of ordinary language, a double meaning, which only the person acquainted with the writer's views would think of. The use of cryptography for purposes of state in England ended, it may be said, with the Peace of 1815. During the Peninsular war the government attached a cryptographer to the office of the Minister for Foreign Affairs to read and write the ciphers received and despatched. It is said that on more than one occasion the minister was unable to comprehend his own cipher.

The earliest elaborate treatise on writing in cipher is the *Steganographia* (Frankf. 1606) of the abbot John Trithemius, a MS. copy of which was bought for a thousand crowns at Antwerp by Dr Dee in 1583. Lord Bacon, who esteemed cryptography one of the most useful arts of his time, framed what he believed a not easily penetrable cipher—in which he employed only *a* and *b*, arranging each of these letters in groups of five, in such collocations as to represent all the twenty-four letters. Thus *aabab*, *ababa*, *babba* conveyed the word *fly*. In his *De Augmentis* he styled this an *omnia per omnia* cipher, believing that in this case preconcertment would be necessary; but in reality any clever modern decipherer could have read any letter composed in such a manner if it were of any length.

Mr Donnelly, in his work *The Great Cryptogram*, endeavours to prove that Bacon inserted a cipher in the Shakespearian plays—which he claims is the work of the great philosopher—but the cipher is of so elaborate a kind that nobody but Mr Donnelly has been able to follow its intricacies. The unfortunate Earl of Argyll used a mode of secret writing which consisted in setting down the words at certain intervals, which he afterwards filled up with other words, making of the whole something intelligible, but of no use to any one else reading the message. The Marquis of Worcester invented a cipher composed of dots and lines variously ordered within a geometrical figure; while Dr Blair made one of three dots, placed over, under, or on the line, by which he could represent no fewer than eighty-one letters, figures, or words. The Doctor, in his able article in *Rees's Cyclopaedia*, declares this cipher to be as nearly as possible undecipherable by strangers; but two years afterwards, Mr Gage, of Norwich, published a pamphlet on purpose to solve Dr Blair's riddle. As he devoted fourteen closely printed octavo pages to the explanation, any description of the cipher is beyond the limits of this article. Mr Thicknesse, a well-known expert of the 18th century, also devised a plan of conveying information in the

disguise of music, the notes, rests, expression-marks, &c., standing for letters.

All the methods, however, of cryptography may thus be summarised: (1) By invisible ink; (2) by superfluous words; (3) by misplaced words; (4) by vertical and diagonal reading; (5) by artificial word-grouping; (6) by stencil-plates cut out so as to show certain words beneath; (7) by using two letters (Lord Bacon's cipher); (8) by transposing the letters; (9) by substitution of letters; (10) by counterpart tabulations; (11) by mixed symbols; (12) by a printed key and code-book, used chiefly in telegrams; (13) by the employment of numerals.

The present century has seen the decline of cryptography for all practical purposes, and the art is now only regarded as a curious study, closely connected with the history of all nations.

Cryptomeria, or JAPANESE CEDAR. This lofty and beautiful hardly coniferous tree (*C. japonica*) is widely distributed in mountain districts of Japan and China, as well as cultivated in many varieties. It was introduced by Robert Fortune in 1842, and has since passed into cultivation. Although originally confused with the cypresses, it is nearly allied to *Sequoia* and *Taxodium*. See CONIFERÆ.

Cryptoprocra, a fierce carnivorous animal of Madagascar, forming a genus and species by itself. It is plantigrade, but resembles a weasel, three feet long, and attacks the largest animals with great ferocity.

Crystalline Rocks, a name given to all rocks having a crystalline structure. The crystalline texture may either be original or superinduced. Thus some crystalline rocks, such as certain calcareous masses, owe their origin to chemical precipitation from water, while others again, such as lavas, have consolidated from a state of igneous fusion. There is another large class of crystalline rocks, the crystalline granules of which present a remarkable foliated character—that is, they are arranged in more or less parallel layers (see SCHISTS). This peculiar schistose structure appears to have been superinduced—the original rocks having been either fragmental or crystalline or both—and the result of great heat and pressure. Such highly altered rocks occur in the neighbourhood of masses of granite, and cover wide regions, where there is abundant evidence to show that the strata have been subjected to enormous compression, crushing, and crumpling—having been folded and fractured and pushed violently over each other for distances of sometimes 15 miles and more. It is therefore believed that pressure and the heat engendered by great earth-movements, and the intrusion of plutonic igneous matter, are among the most potent agencies in the production of schistose structure.

Crystallites, minute non-polarising bodies (the result of incipient crystallisation) occurring in the vitreous portions of igneous rocks. See IGNEOUS ROCKS.

Crystallography (from the Greek *krystallos*, 'ice,' an idea among the ancients being that rock-crystal, which may be taken as a type of crystalline minerals, resulted from the subjection of water to intense cold). Minerals, salts, and inorganic bodies generally (examples, rock-crystal, fluor-spar, alum, and sugar) exist in the crystalline state; and when we examine all crystals, whether occurring naturally or obtained artificially, certain laws have been discovered, and phenomena observed, and these laws and phenomena constitute the science of crystallography. The following are the more important laws and principles of the science:

(1) *Law of Constancy of Angles*.—Crystals of the

same substance may differ much in general appearance, but when the angles between their faces are measured these angles are found constant. Thus the crystals A and B (fig. 1), when cut through in

Fig. 1.

Drawings of two crystals differing much in appearance, but with angles at a shown to be constant when similar sections are made.

the direction xy at right angles to the prism, give the sections shown at A' , B' ; and in each section the angles α will be found the same—viz. 120° ; or again, if the angles between the faces ab , bc , or ac , be measured, they will be found identical in both crystals.

(2) *Law of Symmetry*.—Suppose we cut a crystal in two, and then place the two parts with their cut surfaces on a mirror. The mirror will reflect each part, and may or may not produce the appearance of the original crystal. If the mirror will produce the appearance of the original crystal, we have severed the crystal in a plane of symmetry. Thus with a cube, if we cut it in either of the planes

Fig. 2.

Each of the planes represented by dotted lines is a plane of symmetry.

while with other forms varying numbers of planes of symmetry may be found, until with a sphere there are an infinite number of planes of symmetry; for it is obvious that if a sphere be cut anywhere by a plane passing through its centre, and the half thus obtained be laid upon a mirror, the appearance of a complete sphere will be produced. Now examining all (holohedral) crystals, it is found that they fall into one of the following six categories or systems: (1) *Anorthic System*.—No plane of symmetry—examples, copper sulphate and anorthite. (2) *Oblique System*.—One plane of symmetry—gypsum and washing-soda. (3) *Prismatic System*.—Three planes of symmetry at right angles to each other—barytes, saltpetre, and native sulphur. (4) *Rhombohedral System*.—Three planes of symmetry at 120° to each other—calcite, quartz, and ice. (5) *Pyramidal System*.—Five planes of symmetry—cassiterite, zircon, and idocrase. (6)

Cubic System.—Nine planes of symmetry—fluor-spar, galena, and alum.

(3) *Law of Rationality of Indices*.—The various planes of crystals, as explained below, are indicated in the Millerian system by three numbers, which together form the symbol of the plane. Thus we have planes represented by $1\ 2\ 3$, by $1\ 1\ 1$, by $1\ 1\ 0$, &c. Now the law of rationality asserts that the symbol of a plane must be represented by numbers which are rational—i.e. numbers which can be expressed exactly, not those like $\sqrt{2}$, $\sqrt[3]{4}$, &c., which can only be obtained approximately. Thus by the law of rationality, no plane of a crystal can have such a symbol as $1\ \sqrt{3}\ 5$, $1\ \sqrt{2}\ 0$, &c.

Crystallographic Notation.—Several methods of representing planes of crystals by symbols are in use. Two of these only need be mentioned—viz. Miller's notation and Naumann's notation. In both systems the planes are referred to three axes corresponding in direction to three edges of the crystal.

Let abc (fig. 3) represent parts or parameters cut off from three axes xyz , then in Miller's

Fig. 3.

The plane $1\ 1\ 1$ in Miller's notation.

Fig. 4.

The plane $1\ 2\ 3$ in Miller's notation.

system the plane $1\ 1\ 1$ represents a plane which cuts the x axis at one-oneth of a , the y axis at one-oneth of b , and the z axis at one-oneth of c . Such a plane is indicated by pqr . The plane $1\ 2\ 3$ means a plane which cuts the x axis at one-oneth of a , the y axis at one-half of b , and the z axis at one-third of c . Such a plane is represented by stu , fig. 4. The plane $1\ 1\ 0$ means a plane which cuts the x axis at one-oneth of a , the y axis at one-oneth of b , and the z axis at one-nought of c —i.e. does not cut c at all, or is parallel to it. Such a plane is represented by $uvwx$ in fig. 5.

Fig. 5.

The plane $1\ 1\ 0$ in Miller's notation.

In Naumann's system some form is selected as

the fundamental pyramid of the crystal, and his pyramid, which corresponds to Miller's form, $1\ 1\ 1$, is represented by the letter P in all systems but the cubic (in this system it is called O) and the rhombohedral (in this system it is called R). Thus the planes marked P (fig. 6) form the fundamental pyramid, the planes $\frac{1}{2}P$ are those of a pyramid one-half the height, while the basal plane is represented by oP or a pyramid

Fig. 6.

A crystal with the faces marked in Naumann's notation.

of no height, while the planes ∞P represent a pyramid of infinite height.

Drawing and Mapping of Crystals.—Various modes of representing crystals have been adopted. Perspective drawings are made by projecting the axes according to the rules of Projection (q.v.), then the various planes are indicated, and from these their intersections are known, and these intersections form the drawing of the crystal. Fig. 7 represents one octant of the form 2 1 1

Fig. 7.

Mode of drawing a crystal from projection of axes.

drawn by this method. Some writers represent crystal forms by orthographic projections—that is, represent them in plan and front elevation. Of all methods, however, of representing crystals from measurements made with the goniometer, the most elegant and convenient is that of spherical projections. Two kinds of spherical projection are in use—viz. the *gnomic* and the *stereographic*. Imagine a glass sphere placed within a crystal, as in fig. 8, and suppose the faces of the crystal to move parallel to their original positions until they touch the sphere, and where the faces touch let dots be marked on the sphere.

Fig. 8.

Sphere within a crystal. When planes are moved they touch the sphere where dots are marked.

Thus the face a will produce the dot a' , the face b the dot b' , and so on. When the sphere is thus marked with dots corresponding to the several faces, the next thing is to make a map of the dots in their proper position. If the map is to be made on the gnomonic projection, the sphere is supposed to be placed on the paper on which the map is to be made, and the eye is then placed at the centre of the sphere. The various dots when projected on to the paper as seen by the eye placed at the centre of the sphere produce the map. If the map is to be made on the stereographic projection, suppose a piece of glass to pass through the centre of the sphere as in fig. 9, and let the eye be placed touching the sphere at E, then the dots as they appear on the glass to the eye at E form the map. Such a map of the crystal of fig. 8 is given in fig. 10. In the stereographic projection all great circles on a sphere are represented on the map by either straight lines or arcs of circles, whereas in the gnomonic projection they are represented by straight lines. The map (fig. 10) shows not only the position of the dots or poles, but also great circles passing through

the sphere. These great circles correspond to the planes of symmetry of the cube (fig. 2) and other forms of the cubic system. These stereographic maps, as will be seen by reference to treatises on

Fig. 9.

The eye placed at E sees the dots on lower part of sphere projected on the plane $a b c d$.

Fig. 10.

Stereographic map of the crystal of fig. 8 as obtained by method in fig. 9.

the subject, convey a good deal of information respecting the crystals they portray.

Planes of crystals form a *zone* when the intersections of the planes (i.e. the edges) are parallel to each other. Thus, in fig. 6 the faces oP , iP , P , and ∞P form a zone. Now in Miller's notation these forms have the indices 0 0 1, 1 1 2, 1 1 1, 1 1 0, and it will be noticed that all these symbols have a common ratio—thus, the first and second index are equal to each other. It may be shown that this is universally true; hence, knowing the indices of a plane, we can say whether it is on a particular zone, or knowing that a plane lies in two zones, we can determine its indices. Thus, the planes 1 2 3, 1 2 4, 1 2 5, &c., are all in one zone, as the symbols have the common ratio 1 : 2, and the plane 3 4 5 cannot be on this zone, because its symbol does not contain the ratio 1 : 2.

Holohedrism and Hemihedrism.—Crystals which have all faces present as required by the law of symmetry are termed holohedral. Where, as is often the case, only one-half of these faces are present, the crystal is said to be hemihedral; while if only one-fourth of the full number of faces are present, the crystal is said to be tetartohedral.

Physical Crystallography.—The physical properties of crystals have some interesting relations to the symmetry and form of the crystal, and these properties are included generally with crystallography. Thus, if in the regular system a face is striated or has any peculiarity, this striation or peculiarity will be found on each face which is present by the law of symmetry. Again, most crystals cleave (i.e. break easily) in certain directions, and the cleavage planes follow the law of symmetry. Again, when examined by polarised light, other properties of crystals in relation to symmetry are brought out. Thus, crystals of the regular system (except in a few certain cases) do not doubly refract light, no matter in what direction the light is incident. With crystals of the rhombohedral system and the pyramidal system light is not doubly refracted when it falls parallel to the vertical axis, but in other directions it is doubly refracted; while in the remaining systems two directions can be found in which the crystals of these systems do not doubly refract light, though they do so in all other directions. Again, heat is conducted differently in different systems of crystals. Suppose crystals turned in a lathe into spheres, and that the centre is made suddenly hot, then in the regular system the heat spreads equally, and after a time the surface of the sphere is uniformly raised in temperature; with other systems the effect is different; with the pyramidal and rhombohedral systems a similar experiment would result in the surface of the sphere being heated uniformly over belts corresponding to an equator and parallels of latitude, but the tempera-

ture of the different belts would be different, thus showing that heat is propagated in two directions at right angles to each other with different velocities. With other systems more complex results would be obtained owing to heat being propagated in three directions with different velocities.

When soluble crystals are placed in a solvent the faces are eaten out differently, producing figures termed by German writers 'actzfiguren.' These figures will often indicate the symmetry of the crystal, and have been useful in such determination. As physical properties generally are related to elasticity, Groth states that the best way to define a crystal is that it is a solid body, the elasticity of which is the same in all parallel directions, but on the contrary is different in different directions.

See *A Tract on Crystallography*, by W. H. Miller (Deighton, 1863); *A Treatise on Crystallography*, by W. H. Miller (1839); *Introduction to Mineralogy*, by William Phillips (ed. by Brooke and Miller, 1852); *Crystallography*, by H. P. Gurney (S.P.C.K.); *A Guide to the Mineral Gallery of the British Museum*, by L. Fletcher (printed by order of the trustees); N. S. Story Maskeyne, *A Manual of Crystallography* (Oxford, Clarendon Press, 1889). In the majority of treatises on mineralogy a portion of the work is devoted to crystallography.

Crystalloid is a name given by Graham to a class of substances which when in solution pass easily through membranes; as opposed to *colloids*. Metallic salts, sugar, oxalic acid, are crystalloids. See DIFFUSION, OSMOSE.

Crystallomancy, a mode of divination by means of transparent bodies, at one time very popular. A precious stone, crystal globe, or other transparent object was employed, but a Beryl (q.v.) was deemed most effective. In using it, the operator first muttered over it certain formulas of prayer, and then gave it into the hands of a youth or virgin—none others were pure enough to discern its revelations—who beheld in it the information required. Sometimes the wished-for knowledge was conveyed by means of written characters on the crystal; sometimes the spirits invoked appeared in the crystal to answer the questions asked. Dr Dee was a great adept at Crystallomancy, and two of his magic mirrors—cannel coal and smoky quartz, polished—are now in the British Museum. Even in the middle of the 19th century Lady Blessington's 'magic crystal' was in great repute in the upper circles of London; it figured in the libel case of Captain Morrison, R.N. ('Zadkiel'), v. Sir Edward Belcher (1863).

Crystal Palace. See SYDENHAM.

Csaba, a town of Hungary, 7 miles S. of Bakes by rail. It has a trade in grain, flour, wine, hemp, and cattle. Pop. 32,616.

Csanad, a village in Hungary (pop. 3000), on the Maros, 22 miles E. of Szegedin.

Csardas. See CZARDAS.

Csoma de Körös, ALEXANDER, a Hungarian traveller and philologist, born 4th April 1784 in the Transylvanian village of Körös, was educated first at the college of Nagy-Enyed, and subsequently at Göttingen, where Eichhorn the Orientalist inspired him with a passion for philology. In 1819 he studied Slavonic in Croatia with his customary ardour, and next year started on his pilgrimage to Central Asia, finding his way in Asiatic dress with the most indomitable perseverance by Bagdad and Teheran to Bokhara, thence by Kabul and Lahore to Cashmere and Tibet. He soon began to devote himself to a study of the Tibetan language under the patronage of the English government. Early in 1827 he started on his third journey thither, and remained in the country for three years, completely absorbed in study, and indifferent to the extreme

cold of winter and to privation of every kind. Early in 1831 he arrived at Calcutta, where he completed his Tibetan grammar and dictionary. He was appointed librarian to the Asiatic Society, but no comforts could wean him from his love for travel. In January 1836 he started on another journey to Tibet, but died of fever six days after arriving at Darjeeling in Sikkim, 30th March 1836, a veritable martyr to science. His Life was written by Dr Theodore Duka (1885), who disposed of the assertion so often made, that the traveller's zeal, at least after the years of mere boyhood, was due to a devout imagination that somewhere in the heart of Asia it was possible still to discover the original home of the Magyar race.

Csongrad, a town of Hungary, at the confluence of the Theiss and the Körös, 75 miles SE. of Pesth. The inhabitants, 17,837 in number, are chiefly engaged in the rearing of cattle, fishing, making of wine and soap.

Ctenoid Scales (literally, 'comb-like'). See SCALES.

Ctenophora (literally, 'comb-bearers'), a subclass of Coelenterates (q.v.), representing the climax of activity in that series of animals. The Common Berrie and Pleurobrachia are good types. Venus' Girdle (*Cestum veneris*) is a well-known aberrant form, which has been elongated sideways to a yard or more in length. They are beautifully delicate, free-swimming marine organisms, generally globular in form, moving by means of comb-like plates. These are composed of numerous agglutinated cilia, and disposed along eight meridional rows. The mouth is at one pole of the sphere, two excretory or anal apertures lie at the other, which also exhibits a sense organ and a probable steering mechanism usually known as the 'otolith.' There are numerous alimentary vessels regularly disposed in relation to the main central cavity. In most

Ctenophore, with streaming tentacles.

cases there are two retractile tentacles; the stinging cells so characteristic of Coelenterates are usually modified into 'adhesive cells.' The Ctenophores are hermaphrodite, carnivorous in diet, extremely active in habit, and often phosphorescent. They are connected with the veiled (Craspedote) medusoids by the transitional genus Ctenaria, a medusoid which in some ways looks like a Ctenophore in the making. Some would place them along with Hydromedusa; rather than allow them the rank of a distinct sub-class, Lang has suggested the derivation of some of the lower worm-types from Ctenophora, but other authorities do not regard such a connection as at all probable. See BERÖE, COELENTERATES.

Ctesias, a Greek historian of Persia, was private physician of Artaxerxes Mnemon, and accompanied him in the expedition to crush the revolt of his brother Cyrus, 401 B.C. His *Persika* was a history of Persia in twenty-three books, written in the Ionic dialect, but unhappily only a meagre fragment can be recovered in an abridgment in Photius, and in some portions preserved by Diodorus and other writers. The first six books

contained the history of the Assyrian monarchy down to the foundation of the kingdom of Persia; the next seven continued the history of Persia down to the end of the reign of Xerxes; the remaining ten carried it down to 398, the year in which Ctesias left Persia. Ctesias compiled his history from oriental sources, and it is not wonderful that his statements often contradict those of Herodotus. Of his *Indika* also only an abridgment by Photius is extant. See Gilmore's edition of *The Fragments of the Persika of Ctesias* (1888).

Ctesibius, a Greek who flourished under Ptolemy Philadelphus and Euergetes, at Alexandria, about 250 years B.C., and was famous for his inventions in mechanics. We owe to him and his pupil Hero Alexandrinus, the pump, the bent siphon, and also the discovery of the elastic force of air, and its application as a motive power.

Ctesiphon, a city of Babylonia, on the eastern bank of the Tigris and opposite Seleucia, the common winter residence of the Parthian kings, and finally the capital of the Parthian kingdom. It was conquered by the Romans in 115 A.D., and destroyed by the Arabs under Omar in 637. Its ruins still attest its former magnificence.

Cuando, a name of the Chobe, a tributary of the Zambesi (q.v.).

Cuango, or KWANGO. See CONGO.

Cuba, the most westerly and largest island of the West Indies, and the most important colony left to Spain, stretches in the form of a long narrow crescent, convex on the north side, at the entrance of the Gulf of Mexico, which it divides into two channels—the north-west, 124 miles wide, and the south-west, 97½ miles at its narrowest part. Cuba is 759 miles long from Cape Maisí on the east to Cape Antonio on the west, with a breadth varying from 27 miles to 90 miles, a coast-line of 1976 miles, and an area of about 45,000 sq. m., or, including adjacent islands (of which the Isle of Pines is the largest) and bays, 46,419 sq. m. Only about one-third of the coast-line is accessible to vessels, the remainder being beset by reefs and banks. The shores, low and flat, are liable to inundations, but there are numerous excellent havens. A watershed running lengthwise through the island, rises into mountainous heights only in the south-east, where are the Sierra de Maestra shooting up in the Pico de Turquino to 8400 feet, and the Sierra del Cobre (copper). The mountains, composed of granite overlaid with calcareous rocks, and containing minerals, especially copper and iron, are clothed in almost perennial verdure, wooded to the summits. Carboniferous strata appear in the west, schistose rocks on the north coast. The limestone rocks abound in caverns, with magnificent stalactites. Mineral waters are plentiful. The rivers, running north and south, are navigable for only a few miles by small boats, but are very serviceable for irrigation of the plantations, and supply excellent drinking water. The climate, more temperate than in the other West Indian Islands, is salubrious in the elevated interior, but the coasts are the haunt of fever and ague. No month of the year is free from rain, the greatest rainfall being in May, June, and July. Earthquakes are frequent in the east. Hurricanes, less frequent than in Jamaica, sometimes cause widespread desolation. A hurricane in 1846 demolished 1872 houses, and sank 216 vessels.

The soil of Cuba is eminently fertile, a large part still covered with virgin forest containing magnificent mahogany, cedar, ebony, ironwood, dyewoods, and pine. The vegetation of Cuba also includes *lignum-vitæ*, tamarind, palms, ferns, lianas, &c. Among the cultivated products are sugar, tobacco, coffee, cacao, rice, maize, cotton,

esulent roots, and tropical fruits. Among the animals are a species of tail-less rat peculiar to Cuba, great abundance of birds, including the mocking-bird, a species of vulture (valuable as a scavenger), woodpecker, partridge, flamingo, albatross. Of noxious animals there are the crocodile, scorpion, and mosquitoes. The rivers and seas are well stocked with fish, the turtle abounding in the shallows and sandy places of the beach.

Sugar, for which soil and climate are peculiarly favourable, has long been the chief product of Cuba, though it has for some time been suffering from the low prices. The total production of sugar in 1887 was 626,420 tons; in 1888, 647,861 tons. About nine-tenths of the sugar, and nearly all the molasses, is exported to the United States. Of tobacco of excellent quality, the yield is about 300,000 bales annually. In 1886 the export of tobacco was 181,353 bales, besides 187,941,000 cigars. The mining industry of Cuba has as yet received little attention. The 'Jurugua Iron Company,' formed in 1883, exported to the United States in 1884, 22,000 tons of iron ore; and in 1886, 110,000 tons. In 1888, according to a British consular report, this export had risen to 20,000 tons a month. The ore contains 70 per cent. of pure metal. There are some 1600 sugar plantations in Cuba, 8500 tobacco plantations, and 700 coffee plantations. The total imports into Cuba in 1886 are estimated at 57,000,000 pesos or dollars, and the exports at 80,000,000.

According to De las Peñas, author of the large map of the island (Havana, 1881), the population in 1879 amounted to about 1,500,000, of whom 975,000 were Spaniards and Creoles, 9300 foreigners, 40,000 coolies and other Asiatics, while there were 445,000 negroes and mulattoes, of whom 269,000 were free. In Cuba there are about 1000 miles of railway, and 2810 of telegraph wire. The principal towns, Havana (q.v., the capital, with 250,000 inhabitants), Puerto Principe, Santiago, Nuevitas, and Cienfuegos, are united by railway. Havana, with magnificent harbour, has a royal university; and Santiago has a gymnasium and a seminary.

Judicially the island is divided into twenty-six districts, over each of which is an 'alcaldé mayor' or judge, having under him local judges. The superior tribunal at Havana, 'the Real Audiencia,' is also a council of state which the captain-general consults in all difficult matters of administration. The captain-general, holding office for three to five years with a fixed salary of £10,000 per annum, is at once highest military and civil commander. There are thirty-one political districts, each of which has its ayuntamiento or town-council. The established religion is Catholic, and the ecclesiastical government consists of the archbishopric of Cuba and the bishopric of Havana. All state offices, from the highest to the lowest, are held by Spaniards from Spain.

Cuba, spoken of as the 'Queen of the Antilles,' was first discovered by Columbus in 1492, the discoverer calling it 'the most beautiful land that eyes ever beheld.' It was first settled by Spaniards at Baracoa in 1511. Havana, first settled in 1519, was reduced to ashes by the French in 1538, and again in 1554. For about one and a half centuries Cuba was in constant danger from French, English, Dutch, and West Indian filibusters. In 1762 the English under Lord Albemarle (q.v.) took Havana, which, however, was by the Treaty of Paris next year restored to Spain. Hitherto the whole Spanish trade with the colonies had been in the hands of a single privileged company. During the ten months' English occupation, Havana, open to free trade, showed in its port, instead of ten to twelve ships yearly as formerly, more than one thousand, and agriculture made rapid progress. In 1818 Cuba

was opened to the trade and shipping of all the world, and for some years reached a prosperity surpassing that of the palmiest days of any other West Indian colony. In 1848 and subsequently proposals have been made in the United States for the acquisition from Spain of this fertile and happily situated island. The American war destroying for the time the production of sugar in the southern states, Cuba came in for the inheritance of the sugar industry. The Spanish revolution of 1868 called forth a revolutionary movement in Cuba which was not suppressed till 1878, leaving Cuba with its resources in large part destroyed, and saddled with a heavy burden of debt. In 1870 the Madrid ministry passed a law, which, however, remained a dead-letter, freeing every slave at the age of sixty, and all the future offspring of slaves. A law for the gradual abolition of slavery was passed by the Spanish cortes in 1879, and a law passed in 1886 abolished slavery absolutely.

Hazard (Lond. 1873); *Cuba Past and Present*, by M. M. Ballou (Boston, 1885); *The West Indies*, by C. H. Eden (Lond. 1880).

Cubango, a river of central Southern Africa, which rises in the Benguela country, and, under the name of Tonke, falls into Lake Ngami (q.v.).

Cube, a solid bounded by six equal square faces, opposite pairs of which are parallel; the three edges meeting at any point being at right angles to one another. It is a form of frequent occurrence in nature, especially among crystals (see CRYSTALLOGRAPHY). In arithmetic, the cube of a number is the product of its multiplication three times by itself. This use of the term arises from the circumstance that the solid contents of a cube may be expressed by the third power of the number which expresses the length of one of its edges. Thus, if the edge of a cube be a line of 4 inches, its solid content is 64 cubic inches. Conversely, the cube root of a number is that number which, multiplied three times by itself, produces the first number. For the cube root, see INVOLUTION and ROOT. See also DOUBLING THE CUBE.

Cubebs, or CUBE PEPPER, the dried berries of *Piper Cubeba*, a climbing shrub, a native of Sumatra, Java, and Southern Borneo. The berries are about $\frac{1}{16}$ th of an inch in diameter, and are furnished with a thin stalk a little longer than the berry itself. The fruits of other species of *Piper* are sometimes substituted for the true cubebs, such as those of *Piper longum*, &c., but in general the stalks of these substitutes are either wanting or are less than the length of the berry. Although known to the Arabs in the middle ages, and used in medicine as well as in culinary art, cubebs fell gradually into disuse, till at the beginning of this century all reference to it was omitted in medical books, and its importation into Britain ceased entirely. It is again, however, coming into use. As a stomachic and carminative in indigestion it has a certain value, while in piles and in sore throats its administration is attended with benefit.

Cubebs contains a volatile oil, a crystalline substance called *cubebin*, and resinous bodies, one of which is *cubebic acid*. The cubebin is inactive, while the volatile oil is not believed to have the full virtue of the cubebs. It enters, however, into the composition of a well-known voice lozenge, to which it imparts highly stimulating properties. The diuretic properties are held by some to be entirely due to the resinous bodies, but on this point there is difference of opinion. The dose of powdered cubebs is from one to three drachms, that of the volatile oil ten drops, and of the oleoresin five to thirty drops.

Cubic Equations. A cubic equation in a given quantity is an equation in which the highest exponent of that quantity in any term is 3. Every such equation can be reduced to the form $x^3 + px + q = 0$, where x is the variable and p and q are constants. Every equation of this form has three roots, all of which may be real, or one may be real and two imaginary. An equation containing any number of variables in which the greatest sum of the exponents of the variables in any term is 3 is called a cubic equation. Thus $x^2y + 5y^3 + 6 = 0$ and $xyz + z^2 = 0$ are cubic equations in x , y , and x , y , z respectively. See EQUATIONS.

Cubit (Lat. *cubitus*, 'fore-arm'), a Roman measure of length, supposed to equal the length of the fore-arm from the elbow to the tip of the middle finger. It was $1\frac{1}{2}$ Roman feet ($17\frac{1}{2}$ English inches). The English cubit is $1\frac{1}{4}$ English feet. The cubit of Scripture is generally estimated at 22 inches.

Cubitt, SIR WILLIAM, engineer, born at Dillham, in Norfolk, in 1785, was a miller, cabinet-maker, and millwright until 1812, when he became chief-engineer in Messrs Ransome's works at Ipswich, where he was a partner from 1821 to 1826. In 1823 he joined the Institution of Civil Engineers, and removing to London, was afterwards engaged in most of the public undertakings of his day. The improvement of the Severn and of Boulogne port, the Bute docks at Cardiff, and the water-works for Berlin are among his works. He also invented the treadmill, and constructed the South-Eastern Railway; and for his services in connection with the erection of the Great Exhibition buildings he was knighted in 1851. He died 13th October 1861.

Cucking-stool. See DUCKING-STOOL.

Cuckoo (*Cuculus*), a well-known genus of birds in the order Coccothymophaga, or, according to others, Picarie, and type of a large family (Cuculidae). The common cuckoo (*Cuculus canorus*) is a widely distributed bird, breeding in summer in the northern parts of Europe and Asia, and migrating in winter to Africa, as far as the Cape, or to India. It is best known for the 'coo-coo' cry with which it announces its arrival and that of spring, and for its habit of utilising for its own family the nests and the brooding of other birds. The cuckoo is slightly over a foot in length; the bill is as long as the head, slender and slightly curved; the wings are long and pointed; the tail is also long and rounded; the upper part of the shank is feathered.

Cuckoo.

The upper surface is ashen gray, the belly and legs are whitish with undulating transverse brown lines, the tail is spotted with white above, and the root of the bill and the feet are yellow. The young birds

are blackish, and mottled with yellow and gray. A reddish variety occasionally occurs. The bird arrives in North Europe in April or May, and leaves again in August or September. Its cheerful call ceases to be heard about the middle of June. Predominantly an arboreal bird, it is rare in treeless districts. Each cuckoo seems jealously to 'preserve' a certain territory for itself. Like the other species of *Cuculus*, it is a shy, restless, unsocial bird. It is extremely valuable on account of its insatiable appetite for caterpillars. The hairy forms are especially delighted in, and the indigestible hairs form a felt-like coating in the stomach. The female lays its eggs singly (sometimes to the number of eight), each in the nest of some suitable bird, choosing such as feed their own young on insects—in order of preference, hedge-sparrow, water-wagtail, titlark, yellow-hammer, green linnet, and whin-chat. The young cuckoo, unconsciously reared by its foster-parents, manages to secure the bulk of the food-supply, and in the struggle for existence completely monopolises the nest, ousting the rightful brood. Stories of the ungrateful young bird devouring its foster-parent are entirely mythical. Nor has it been shown that the adult ever sucks the eggs of other birds. The males greatly outnumber the females. The latter have somewhat darker feathers, and a somewhat less emphatic note. The males are said to be very passionate in their love-making, but there is no regular pairing or continued attachment. The musical interval between the cuckoo's two notes is not uniform, and varies from a minor to a major third (the latter being that adopted in Beethoven's reproduction). See *Nature*, vol. xxxvi. p. 344.

The genus *Cuculus* includes about a score of other species, restricted to the eastern hemisphere. In the same family as the true cuckoos are several important genera: The Honey-guide (*Indicator*), of Ethiopian distribution, feeding chiefly on wild bees, and directing attention to their nests; the Golden Cuckoo (*Chrysococcyx*); the Jay-cuckoo (*Coccyzus*), utilising the nests of crows and magpies; *Eudynamis*, of similar habit; *Scythrops*, a very large form in Australia, New Guinea, and the Celebes; the swift 'Road-runner' or 'Ground Cuckoo' (*Geococcyx*), of California; the grub-eating Ani-bird (*Crotophaga*, q.v.); the Coucal or Spurred Cuckoo (*Centropus*), with the claw of the inner toe prolonged into a great spur. An East African cuckoo ('Tepe-tepe') is a delightful song-bird. The American Cuckoo (*Coccyzus americanus*) is particularly interesting, since it makes but a very rudimentary nest, has a very irregular way of laying, and exhibits an unnatural indifference to its young. Its egg is occasionally found in the nest of other birds. These facts, according to Burroughs, raise the question whether the American cuckoo 'is slowly relapsing into the habit of the European species, which always foists its egg upon other birds; or whether, on the other hand, it be not mending its manners in this respect.'

The parasitic habit of our common cuckoo demands further attention, as one of the strangest of bird habits. The facts, which are very hard to explain, may be thus summarised: (1) The habit of utilising the nests and brooding patience of other birds is not common to the genus. It is also the practice of an Australian species, and of some related genera, and is occasionally exhibited by the American representative. Professor Newton notes that a few of our common birds, 'whether by mistake or stupidity, not unfrequently lay their eggs in the nests of others.' In the genus *Molothrus*, allied to starlings, and far separated from cuckoos, the various species exhibit a gradual perfecting (if we may use the term in such a connection) of the parasitic habit. (2) The *modus operandi* of the

habit is usually as follows: The cuckoo selects the nest of an insect-eating bird, much smaller than herself, and often with eggs approximately like her own. Into this, say of a hedge-sparrow, she lifts her egg with her bill, having previously laid it upon the ground. After an interval of two or three days, she repeats the process in another nest. The hedge-sparrow or other bird, all unaware apparently of what has happened, sits on the cuckoo-egg along with her own. The young cuckoo is generally hatched first, and is restless and uneasy until it has got rid of the other eggs or young birds. This it does with considerable exertion, and sometimes with a real struggle, by lifting the living burden upon its back and throwing it over the side of the nest. Thereafter it remains sole though wrongful possessor, and is reared in peace. (3) Among the facts which make the habit a success, the following should be noted. The relatively small size of the cuckoo's egg is striking. 'The egg of the cuckoo is not any larger than that of the skylark, although an adult cuckoo is four times the size of an adult skylark.' This makes the duping of the small birds easier, if, indeed, they have any suspicions. The laying of the egg in a small bird's nest makes the ousting work of the young cuckoo an easier task. In many cases, as already noted, the cuckoo's egg is coloured approximately like those of the victimised foster-parent. Till the young cuckoo is about twelve days old, when the disposition for turning out its companions begins, according to Jenner, to decline, its broad back has a curious depression in the middle. The presence of this cavity makes it easier for the restless and still sightless nestling to bear up and toss over the eggs or young birds which interfere with its desire for sole possession. (4) The advantage to the young bird, which earns by its exertions plenty of growing-room and an extra portion of food, is obvious enough. The individual parent is also saved both time and trouble, as well as all the patient sacrifice of brooding. Jenner has pointed out that the advantage to the species is probably this, that by leaving their eggs to other birds to incubate, the cuckoos are able to have a numerous progeny reared in the short period of their stay in northern Europe. Or, to put it in another way, the parasitic habit enables the cuckoos to migrate earlier. Hence Darwin believed the constant parasitic habit of our cuckoo to have been derived from its occasional occurrence (as in the American form) through the action of natural selection. Those cuckoos which fell in with the trick succeeded better than their neighbours, till gradually only those survived in whom the trick had become habitual.

It is interesting in this connection to note the occasional reversion of a cuckoo to parental responsibilities. Mr Romanes has given a detailed discussion of the subject in his work on *Animal Intelligence*, and also comes to the conclusion that 'we are justified in setting down the instinct to the creating influence of natural selection.' It ought not, however, to be overlooked that all the cuckoos are solitary, unsocial birds; that the American genus is said to be immorally uninterested in the fate of the young; that the species of *Molothrus*, which has most completely developed the parasitic habit, is extremely careless about the brood, and often drops its eggs on the bare ground. The habit may be regarded not so much as requiring special explanation, as an expression of a general constitution or habit of life. Brehm describes the cuckoo as a greedy, discontented, ill-conditioned, passionate, in short, decidedly unamiable bird. It seems plausible, therefore, to suggest that one dominant 'physiological tendency' or mood shows itself in the restless selfishness of the nestling, in the

jealous, solitary individualism of the adult, in the preponderance of males, in the very note, in the relatively small size of the egg, and in the parasitic habit as the most striking outcrop.

The folklore of the cuckoo is almost inexhaustible in every country of Europe. It has the gift of prophecy as the herald of spring and of long life, the prelude of storms, of prosperity, and of speedy marriage to maidens. Countless superstitions, and those of the most varied character, are connected with its origin, the cause of its cry, its winter transformation into a hawk, as well as with the first hearing of its call, the hearer's occupation at the moment, and the direction from which it comes; while as many proverbs play upon the monotony of its note, its supposed stupidity, and its obvious connection with cuckoldom, from its habit of depositing its offspring with alien parents. It has only been by a strange transference of meaning that the name *cocu* or *cuckold* has been transferred from the paramour to the unsuspicious husband, unless *cuckold* means, as explained by Littré, one who has been *cuckoo-ed* or treated after the manner of the cuckoo. The earliest English song extant (13th century) is an expression of the joyousness of the first cuckoo-call.

For details of Cuckoo folklore, see Mannhardt in the *Zeitschrift für Deutsche Mythologie*, vol. iii. pp. 209-298; James Hardy's 'Popular History of the Cuckoo,' in Part II. (1879) of *The Folklore Record*; and Swainson's *Folklore of British Birds* (1886).

Cuckoo Spit. See FROTH-FLY.

Cucumber (*Cucumis*), a genus of Cucurbitaceæ. The Common Cucumber (*C. sativus*), distinguished by heart-shaped, acuminate pentangular leaves, which are rough with hairs

Common Cucumber (*Cucumis sativus*):
a, fruit.

approaching to bristles, and oblong fruit, is a native of the middle and south of Asia, and has been cultivated from the earliest times. Its fruit forms an important article of food in its native regions, the south of Europe, &c., and an esteemed delicacy in colder countries, where it is produced by the aid of artificial heat. Many varieties are in cultivation, with fruit from 4 inches to 2 feet long, rough, smooth, &c. Young cucumbers are much used for pickling, and are called *gherkins*; a small fruiting variety is selected for this purpose. The cucumber is cultivated in fields even in the south of England, for the supply of the London

market; but in all parts of Britain the plants required for the purpose of growing either in the open or under glass must be reared in a hotbed in spring. In the northern parts it can only be successfully cultivated in frames during summer. A large trade is now done in winter crops of cucumbers, which are grown in well-heated, specially constructed glass-houses. In many parts of the United States it will, if planted late enough to escape the frosts, grow well with almost no care. But it requires rich soil, much moisture, and heat. To this genus belong other species valued for their edible or ornamental fruit, but all that are popularly named cucumber are not properly *Cucumis*, but merely species or varieties belonging to allied genera. *Dudaim* (*C. Dudaim*) is a highly fragrant, handsome fruit, with insipid flavour and flaccid flesh, often grown in this country by gardeners under the name, *Queen Anne's Pocket Melon*, simply for its attractive appearance, the fruit being about the size of an ordinary orange, and beautifully barred with green and orange or deep orange-red. (*Dudaim* is the Hebrew name rendered *Mandrake* in Scripture.) Connemion is the fruit of *C. conomon*, which is grown everywhere in Japan, and preserved and sold as an article of food. *C. auraria*, a West Indian species, with fruit about the size and shape of a pullet's egg, is esteemed as an ingredient in soups, and is also eaten raw, but considered inferior in that state to the common cucumber. The Snake Cucumber (*C. flexuosus*) has fruit of great length which is eaten either pickled or raw, and has similar qualities to the common cucumber. A number of species of Cucurbitaceæ are natives of the United States, but they are all of small economic importance. For other representatives of the natural order Cucurbitaceæ, see COLOCYNTH, ELATERIUM, MELON, &c. See, too, May's *Cucumber Culture* (1880).

Cucurbitaceæ, an important order of corollifloral dicotyledons, of which the 500 species are mostly herbaceous climbers, inhabiting the warmer regions of the globe; only one, the Common Bryony (q.v.), reaching the south of England. The young shoots and leaves of many species are used as potherbs, and the persistent rhizomes or roots of others are sometimes esteemed on account of their store of starch. Acidity, however, is a common characteristic of the order; and Bryony, Elaterium, and especially Colocynth (q.v.), are of old medicinal repute. But the central importance of the order is due to the characteristic fruit, which is technically known as a *pepo*, but which may be regarded as a large and many-seeded berry, with its more or less succulent pulp protected by a hardened wall. The many specific and varietal forms are known as Cucumbers, Melons, Gourds, Pumpkins, Squashes, Vegetable-marrows, Bottle-gourds, &c., and are described under separate articles. The seeds of some species are medicinal, others edible, while the fibro-vascular skeleton of the fruit of an Egyptian species of *Luffa* (loofah) is a familiar adjunct of the bathroom.

Cúcuta, SAN JOSÉ DE, a town in the Colombian department of Santander, on the Rio Zulia, 35 miles S. of Puerto Villanizar by rail. It is the third commercial town of the republic, a centre of coffee and cacao cultivation. It was destroyed by earthquake in 1875, but has been well rebuilt. Pop. 13,000.—MARSARIO DE CÚCUTA, to the SE., was the seat of the first Colombian congress in 1821, and the birthplace of the patriot General Santander (1792-1840). It has large plantations of coffee and cacao. Pop. 6000.

Cud, the sodden bolus of hastily swallowed fodder which ruminants drive from their paunch and honeycomb stomach back again into the

mouth. There the cud is leisurely chewed, and the semifluid result passes down again into the stomach, usually into the manyplies. One bolus is driven upwards after another until the greater part of the cropped herbage has been chewed. See RUMINANTS.

Cudbear. The lichens from which, and the process by which, this dyestuff is obtained, are described under the head ARCHIL, cudbear being simply archil paste dried and ground. It is very useful to the wool-dyer for producing, in conjunction with indigo, logwood, fustic, and other colouring materials, rich shades of brown and chocolate. The preparation of archil, known as French purple, was used for a short time in calico-printing, and produced fine and delicate shades of purple, but its employment for this purpose ceased soon after the introduction of aniline mauve as a dyestuff. The ancient Cretan purple was probably obtained from the same source as archil. The name cudbear is a corruption of *Cuthbert*, and is derived from that of Dr Cuthbert Gordon; under whose management the manufacture of this dyestuff was begun in Leith about the year 1777, by Mr Macintosh of Glasgow.

Cuddalore (*Kūḍalūr* or *Gudulūr*), the chief town in South Arcot, Madras, on the Coromandel or east coast of Hindustan. It is situated on a backwater formed by the confluent estuaries of two rivers, 16 miles S. of Pondicherry, and 127 S. of Madras by rail. It has a large trade by land with Madras in oils, indigo, and sugar, and exports grain by sea. Though the river itself is silted up, and admits only native craft, yet there is good anchorage off-shore at the distance of a mile and a half. Cuddalore was at one time a place of great strength; and in that respect it was frequently an object of contention in the wars which, during the later half of the 18th century, so long desolated this neighbourhood. In 1758 it was taken by the French from the British, who had held it for 77 years; and was finally ceded to the British in 1785. Pop. (1881) 43,545.

Cuddapah, a town in the province, and 161 miles NW. by rail of the city, of Madras. It stands, at the height of 507 feet above the sea, near the south bank of the northern Pennar, which flows into the Bay of Bengal. Till 1868 it was a military cantonment. Pop. (1881) 18,982.—The district of Cuddapah, partly lowland and partly highland, has an area of 8745 sq. m., and a pop. (1881) of 1,121,038. It has been British since 1800.

Cuddesden, a village of Oxfordshire, 6 miles ESE. of Oxford. Here is the palace of the bishops of Oxford, rebuilt by Bishop Fell in 1679, with a chapel added in 1846 by Bishop Wilberforce, to whom the adjoining theological college (1834) also owes its existence. The church is a fine old cruciform building.

Cuddy was the name first applied in East India trading ships to a cabin under the poop, where the men messed and slept. The same name was afterwards given to the only cabin in very small vessels, and sometimes to the cooking-room.

Cudweed, the popular name of many small inconspicuous species of composite weeds of the genera *Gnaphalium*, *Filago*, and *Antennaria*, the stems and leaves of which are more or less covered with a whitish cottony down. The heads of the flowers consist, in great part, of dry involucre scales, and may be kept for a long time without undergoing much apparent change, so that they may be reckoned among *Everlasting Flowers* (q.v.). *Antennaria dioica* (also called Cat's-foot) is very frequent in dry mountain-pastures. All the three genera are represented in the United States,

where *Gnaphalium polycephalum* has some repute in domestic medicine.

Cudworth, RALPH, the chief figure in the group of 'Cambridge Platonists,' was born in 1617 at Aller, in Somersetshire, and admitted pensioner of Emmanuel College, Cambridge, in 1632. He graduated B.A. in 1635 and M.A. in 1639, and was in the same year elected fellow of his college, where he became a popular tutor. In 1645 he was appointed by parliament Master of Clare Hall, and in the same year regius professor of Hebrew. In 1650 he was presented to the college living of North Cadbury, in Somersetshire, and in 1654 was elected Master of Christ's College, an appointment the confirmation of which at the Restoration his acquiescence with the rule of the Commonwealth did not prevent. In 1662 he was presented by Archbishop Sheldon to the rectory of Ashwell, Hertfordshire; and in 1678 he was installed prebendary of Gloucester. He died at Christ's College, July 26, 1688. His daughter Damaris, who became the second wife of Sir Francis Matcham of Oates, in Essex, was a friend of Locke, and herself wrote a well-reasoned *Discourse concerning the Love of God* (1696).

Cudworth's great work, entitled *The True Intellectual System of the Universe*, was published in 1678. It is a learned, ample, and discursive work, singularly large-minded and sagacious; but its logical consistency as a consecutive argument is somewhat marred by discussions on such subjects as the true meaning of the pagan mythology, and the relation of the Platonic and Christian trinities. Its aim was to establish the reality of a supreme divine Intelligence against the materialism of Democritus and Epicurus, the 'atheism of atomicism;' to vindicate the eternal reality of moral ideas against the old nominalists and their successors; and to prove the reality of moral freedom and responsibility in man as against pantheistic naturism and stoicism. The only basis for a philosophy of religion rests on the conception of man as a free moral subject, capable of choosing good or evil. The portentous erudition of this famous treatise, and the redundant fullness of its endless digressions, with its strange Alexandrian amalgamation of fancy and speculation, have tended to obscure its real merits. Perhaps its most honourable distinction is the marvelously honest and impartial statement of the best arguments of his antagonists, which, indeed, laid him open to the charge of having fallen into the same heresy with Milton and with Clarke, and even into atheism, simply for being just to the arguments of atheistic writers. 'He has raised,' says Dryden, 'such strong objections against the being of a God and Providence that many think he has not answered them'—'the common fate,' adds Shaftesbury, 'of those who dare to appear fair authors.'

Cudworth's admirable sermon, preached before the House of Commons in 1647, shows the best features of that much-abused Latitudinarian school to which he belonged, and, says Mackintosh, 'may be compared even to Taylor (*Liberty of Prophesying*, published the same year) in charity, piety, and the most liberal toleration.' In its insistence upon the co-ordinate relativity of all knowledge, and the connection of religion with life and morality, the author lays down a sound basis for a harmony between philosophy and religion, between reason and faith. Many of Cudworth's MSS. still lie unprinted. His *Treatise concerning Eternal and Immutable Morality* was published by Bishop Chandler in 1731, and is a contribution of real value to ethics. See vol. ii. of Tulloch's *Rational Theology in England in the XVII. Century* (1872), and vol. ii. of Dr Martineau's *Types of Ethical Theory* (1885).

Cuenca, a picturesque decayed city of Spain, 85 miles ESE. of Madrid. It stands on a rocky hill-girt eminence, 2960 feet above the sea-level, at the confluence of the Jucar and Huécar—the latter spanned by the noble bridge of San Pablo (1523), 150 feet high and 350 long. Of Moorish origin, Cuenca has narrow, crooked streets, and a very interesting cathedral (1177–1669). Pop. 7549. —Cuenca gives name to a mountainous, well-watered province, yielding excellent timber, honey, wine, and grain, with good pasture, and various minerals, including iron, coal, copper, and silver. Area, 6726 miles. Pop. (1886) 242,809.

Cuenca, a city of Ecuador, on the Rio Paute, 190 miles SSW. of Quito, stands on a fertile tableland, 8469 feet above the sea, and enjoys a perpetual spring, with a mean temperature of 58° F. Its streets are wide, and several canals intersect the town; the principal buildings are the cathedral and high school. There is some trade in cheese and grain, and manufactures of hats, woollens, earthenware, and candied fruits. Pop. (including the Ejido, or Indian quarter) 30,000.

Cuernavaca, capital of the Mexican state Morelos, lies in a lovely and fruitful valley, about 40 miles S. of Mexico city. It has a church built by Cortes, an agricultural school, and refineries of sugar and brandy. Pop. 17,000. Near by is the famed *teocalli* of Xochicalco, with five terraces.

Cuevas de Vera, a town in the Spanish province of Almería, situated on the Almanzora. It has an old Moorish castle, and a considerable industry in connection with the silver-mines of the neighbouring Sierra Almagrera. Pop. 20,644.

Cufic. See KUFIC.

Cui Bono? ('for whose advantage?'), a Latin phrase not infrequent in Cicero and elsewhere, and very common in modern newspaper English, usually in a somewhat erroneous sense, as if equivalent in meaning to 'what's the good?'

Cuirass. See BREASTPLATE, ARMOUR.

Cuirassiers are heavy cavalry wearing the 'cuirass' and helmet. They represent the troopers of the 16th and 17th centuries, who were similarly protected. In the British army no regiments are officially styled cuirassiers, but the two regiments of Life Guards and the Royal Horse Guards were given steel cuirasses in 1821, which, however, they do not wear on active service. The price of one is £3, 6s. See GUARDS. There are twelve cuirassier regiments in the German army, the cuirass being of white metal with a brass plate. The French have also twelve regiments of cuirassiers, having steel cuirasses with a brass plate. Russia has four regiments of cuirassiers, whose cuirass of iron, with a thin layer of copper, weighs 30 lb. From 13½ to 16 lb. is the weight of those of other armies. Napoleon III. at one time maintained a bodyguard of cuirassiers, called 'Cent-gardes,' who wore cuirasses of aluminium, much lighter than steel ones, but, like them, not proof against a rifle-bullet striking them directly.

Cujacius, properly JACQUES DE CUJAS or CUJAUS, jurist, born in 1522, was the son of a tanner of Toulouse. After studying law, he lectured on the *Institutes* at Cahors, Bourges, and Valence (1554–67); lived at Turin and Grenoble; and after repeated changes, finally settled in 1577 as professor at Bourges, where he resided till his death, October 4, 1590. His great reputation as a jurist was founded on a lucid exposition of Roman law, based on conscientious study of the original authorities. He had in his library 500 MSS. on Roman law, and by his emendations contributed greatly to remove the obscurities of jurisprudence. A complete collection of his works was edited by

Fabrot (10 vols. Paris, 1658), and has since been frequently republished—as at Turin in 1874 (9 vols.). See Spangenberg's *Cujacius* (1822).

Culdees, or KELDEES (Celt. *Ceile De*, 'a companion of God'; Lat. *Colidei*, *Culdei*, *Calidei*, *Keldei*, *Keledei*), the name given to an ancient order of ecclesiastics with monasteries in Scotland and Ireland, those in the former country being best known. In England and Wales only two instances of their occurrence seem to be authenticated—the first, where the canons of St Peter's at York were called Culdees in the reign of Athelstan (924–31), and the second, where Giraldus Cambrensis, writing about 1190, describes the island of Bordsey on the coast of Carnarvon as inhabited by 'most devout monks called celibates or Culdees.'

The origin and early history of these bodies is involved in almost hopeless obscurity. The name is not mentioned in the works of Adamnan, Eddi, or Bede, and makes its first appearance only about the 8th century. The conclusion at which Dr Skene arrives is 'that the Culdees originally sprang from that ascetic order who adopted a solitary service of God in an isolated cell as the highest form of religious life, and who were termed *Deicolæ*; that they then became associated in communities of anchorites or hermits; that they were clerics, and might be called monks, but only in the sense that anchorites were monks; that they made their appearance in the eastern districts of Scotland at the same time as the secular clergy were introduced, and succeeded the Columban monks, who had been driven across the great mountain-range of Drumalban, the western frontier of the Pictish kingdom; and that they were finally brought under the canonical rule along with the secular clergy.'

When the Culdees appear clearly in history in the 12th century each monastery was evidently an independent community, connected with the others by no ties whatever, and owning no control except that of its own abbot, in this and other respects resembling the secular canons or monastic 'families' of England, Ireland, and the Continent in the 11th century. The monasteries seem indeed to have undergone a similar secularising process to that which took place in the Northumbrian Church after the withdrawal of the Columban clergy, when, according to Bede, false monks, under pretext of founding monasteries, purchased for themselves territories, and caused 'these to be assigned to them by royal edicts for an hereditary possession.' There seem to have been at this period two sections in each community, one still performing divine service and other religious duties pertaining properly to the body; while the other had become thoroughly lay, and so free from monastic discipline as to marry. Indeed, if a tradition of the 16th century can be received as authority for what passed in the 12th, the Culdees of Dunkeld were all married; but, like the priests of the Greek Church, lived apart from their wives during their period of service at the altar.

According to the records of the see of St Andrews, the state of the Culdee monastery there (and it may probably be taken as typical of all the rest) was in the middle of the 12th century far from satisfactory. They tell that there were thirteen Culdees holding their office by hereditary tenure, and living rather according to their own pleasure and the traditions of men, than after the rules of the holy fathers; that some few things of little importance they possessed in common; that the rest, including what was of most value, they held as their private property, each enjoying what he got from relatives and kinsmen, or from the benevolence granted on the tenure of pure friendship, or

otherwise; that after they became Culdees they were forbidden to have their wives in their houses, or any other women of whom evil suspicion could arise; that the altar of St Andrew was left without a minister, nor was mass celebrated there except on the rare occasion of a visit from the king or the bishop, for the Culdees said their own office after their own way in a corner of the church. The first attempt to reform this state of matters was made by Queen Margaret, and her efforts were followed up by her sons, Alexander I. and David I.; so that from the time of the appointment of Turgot to the see of St Andrews, when we are told that 'the whole rights of the Keledei over the kingdom of Scotland passed to the bishopric of St Andrews,' the history of the Culdees is simply that of a vain resistance to foes backed by all the weight of the royal power.

If tradition could be trusted, the first appearance of Culdees in Scotland was later than in Ireland, and should be placed about the middle of the 9th century. A leaf of the Register of St Andrews, written about 1130, relates that Brude, the son of Dergad, the last king of the Picts (who ceased to reign about 843), gave the island, since called St Serf's Inch, in Lochleven, to God, St Servan, and the Culdee hermits serving God there. They were governed by an abbot; and about the year 1093, during the rule of Abbot Ronan, they gave up their island to the Bishop of St Andrews on condition that he should find them in food and raiment. On this island they remained in peace, receiving grants of lands or immunities from all the kings of the Scots from the time of Macbeth till that of David I.; but in 1144, Robert, Bishop of St Andrews, gave their island, and all their possessions, including their church vestments and their books (a complete list of which is given in the charter), to the newly-founded Canons Regular of St Andrews, in order that a priory of that rule might supplant the old abbey of Culdees on St Serf's Inch. The bishop's grant was enforced by a charter from King David, in which it was ordered that such of the Culdees as chose to live canonically and peacefully under the new canons should remain in the island. We hear no more of the Culdee hermits of Lochleven.

The Culdees of St Andrews were of more importance than those of Lochleven, and when the Canons Regular were established there, the members of the older body were treated much more considerately than their unfortunate brethren of St Serf's Inch, those who refused to become Canons Regular being allowed to retain a liferent of their revenues. Not only was this so, but they had sufficient influence to manage to remain a distinct community down to the early part of the 14th century, and were even able to assert their right to take part in the election of the bishop till 1273. In that year they were excluded under protest, and in 1332 they were excluded entirely, and thereafter the name seems to have disappeared.

The Culdees of the church of St Mary at Monymusk, in Aberdeenshire, appear to have been settled by the Bishop of St Andrews towards the end of the 11th century. In the beginning of the 13th century they are found making a claim to be regarded as Canons Regular, which was, after an appeal to Rome, settled by a compromise.

Culdees are found at Abernethy, in Strathearn, about 1120. In the end of that century part of their possessions passed to their hereditary lay-abbot (the founder of the noble family of Abernethy), and in 1273 they were transformed into Canons Regular. After a similar division at Brechin, the prior and his Culdees were absorbed into the chapter of the new bishopric, founded by King David I. about 1145, and in less than a hundred years the name of Culdee disappears. The same

silent change of Culdees into secular canons took place during the 13th century at Dunblane, at Dunkeld, at Lismore, at Rosemarky, and at Dornoch. At Dunkeld, as at Brechin and at Abernethy, great part of the Culdee revenues was held by a lay-abbot, whose office was of such mark as to be hereditary in the royal family. The father of 'the gracious Duncan,' and the son of St Margaret, were Culdee abbots. Culdees are found holding land at Monifieth, near Dundee, about 1200; at Muthil, in Strathearn, in the beginning of the 13th century; and at Iona in the middle of the 12th.

The Culdees of Armagh, dissolved at the Reformation in 1541, were resuscitated for a brief space in 1627. Their old possessions—among which were seven town-lands, containing 1423 acres, seven rectories and four vicarages, were in 1634 bestowed upon the vicars-choral of the cathedral. There were at least seven other houses of Culdees in Ireland—viz., at Clonmacnois, Clondalkin, Devenish, Clones, Popull, Monanincha, and Sligo.

Such is a concise recapitulation of all that is certainly known of the Culdees. Before their history was ascertained, opinions were held regarding them which now find few if any supporters among archaeologists. It was believed that they were our first teachers of Christianity; that they came from the East before corruption had yet overspread the church; that they took the Scriptures for their sole rule of faith; that they lived under a form of church-government approaching to Presbyterian parity; that they rejected prelacy, transubstantiation, the invocation of saints, the veneration of relics, image-worship, and the celibacy of the clergy; and that they kept their simple worship and pure doctrines undefiled to the last, and were suppressed only by force and fraud, when the Roman Catholic Church triumphed over their older and better creed. For all this it is now clearly seen that there is no foundation. There is no reason to suppose that the Culdees differed in any material point of faith, discipline, or ritual from the other clergy of the British Islands and Western Christendom.

See Reeves, in the *Proceedings of the Royal Irish Academy* for 1860, and his *Culdees of the British Islands* (1864); and Skene's *Celtic Scotland*, vol. ii., whose views have found acceptance both with Catholics and Presbyterians. The opinions formerly held regarding the Scottish Culdees (controverted by Pinkerton and Chalmers) will be found in Selden's preface to the *Decem Historiæ Anglicanæ Scriptores*, and Jameson's *Historical Account of the Ancient Culdees* (1811).

Culenburg, or KULENBURG, a town of Holland, 11 miles SSE. of Utrecht, on the left bank of the Lek, which is crossed here by a railway viaduct 1420 yards long. Pop. 6798.

Culiacan, an ancient city of Mexico, on the Rio de Culiacan, 30 miles from the W. coast, and 100 SE. of Sinaloa. Pop. 7878.

Cullawan Bark, also called CLOVE BARK, an aromatic bark, the product of the *Cinnamomum Cullawan*, a tree of the same genus with the Cinnamon (q.v.) tree, growing in the Molucca Islands. It has an odour resembling that of nutmeg and cloves, and was formerly employed to some extent for cases of indigestion, diarrhoea, &c.

Cullen, a fishing-town of Banffshire, on the Moray Firth, 67 miles NW. of Aberdeen by railway (1885). Backed by the conical Bin Hill (1050 feet), it has a harbour formed in 1817-34, and a cruciform parish church, which was founded by Robert Bruce, whose second queen died here, and which in 1543 was made collegiate. Cullen House, a seat of the Earl of Seafield, is a Scottish baronial pile, enlarged and remodelled in 1861. Cullen has been a royal burgh since about 1200, and unites with Elgin and five other places to

return one member to parliament. Pop. (1841) 1423; (1881) 2033.

Cullen, PAUL, a great Irish churchman, was born near Ballymore, in County Kildare, April 27, 1803. After a brilliant course in the Collegio Urbano of the Propaganda at Rome, he was ordained priest in 1829, and filled in succession the offices of vice-rector and rector of the Irish College in Rome, and rector of the Propaganda College. During the period of Mazzini's power in Rome in 1848, Cullen astutely saved the property of his college by placing it under American protection. At the close of 1849 the three names sent up to the pope having been passed over, Cullen unexpectedly found himself nominated to the archbishopric of Armagh and primacy of Ireland. He was consecrated early in the following year, and at once commenced a vigorous and uncompromisingly ultramontane reign of eight-and-twenty years, in which he established lasting memorials to his memory in new churches, schools, convents, and hospitals, such as the Mater Misericordiarum. He denounced mixed education in every form, and from the outset opposed all revolutionary and anti-constitutional opposition to the crown. His vigorous denunciations of Fenianism made him many enemies among the more hot-headed Irishmen, but greatly increased the respect of English Protestants for a church that would make no terms with crime, even when committed by its own children. At the Synod of Thurles in 1851, principally by Cullen's persuasion, the establishment of a Catholic university in Ireland was recommended. Translated to Dublin in 1852, he was created a cardinal priest in 1866, the first Irishman who had reached that elevated rank. One of the majority at the Vatican Council, he long enjoyed the familiar friendship of Pope Pius IX. He died at Dublin soon after his return from a journey to Rome, October 24, 1878.

Cullen, WILLIAM, M.D., physician, was born at Hamilton, Lanarkshire, on 15th April 1710, his father being factor to the Duke of Hamilton. After learning his profession, first as apprentice to a surgeon-apothecary in Glasgow, next as surgeon on board a West Indian trading ship, and then as assistant to an apothecary in London, he returned to Scotland in 1731, and commenced practice in his native county. Feeling the necessity of more systematic study, he spent two winters at Edinburgh University under Munro primus, and then removed to Hamilton, where he soon secured a good practice. One of his articulated pupils was William Hunter (q.v.), to whom he became extremely attached; and it was agreed that one of them should be alternately allowed to study during the winter, while the other carried on the practice. Cullen spent the first winter at Edinburgh, and it is at this time that he appears to have taken an important part in founding what is now known as the Royal Medical Society. It being Hunter's turn next year he went to London, and having attracted attention there, did not return, Cullen generously cancelling the articles. In 1740 Cullen graduated M.D. at Glasgow University, gave up surgical work, and soon after established himself in Glasgow as a physician. At that time there was not in Glasgow any regular course of medical study, and Cullen occupied himself much in the foundation of a medical school, himself lecturing on various subjects. One of his pupils was the famous Dr Joseph Black (q.v.). Cullen's labours resulted in his appointment to the chair of Medicine in the university, which he occupied four years. In 1755 he was persuaded to leave Glasgow for Edinburgh, and for the next thirty-five years was one of the mainstays of the Edinburgh medical

school. During this long period he occupied successively the chairs of Chemistry, Institutes of Medicine, and Medicine, besides teaching clinically in the Royal Infirmary all the time.

Living as he did in what might be termed the renaissance period of the history of medicine, Cullen was essentially a man of his time, and did much to advance the science. For many centuries all disease had been referred to disorders of the fluids of the body. Just before Cullen's time, Boerhaave had added to this a pathology of the 'fibres' still strongly tinged with the old fluid or humoral pathology. To Cullen is largely due the recognition of the important part played by the nervous system both in health and disease. He denied the theory supported even by Boerhaave; that the brain was an excretory organ and the nervous influence a fluid. Many of his speculations as to reflex nervous action, the possible presence in a single nerve of both sensory and motor fibres, and the connection of sensory and motor nerves with the anterior and posterior nerve roots, have now been proved to be facts. He had a singularly open and candid mind, and while himself introducing the use of several new drugs, as oxide of antimony and tartar emetic, was careful to distinguish between the action of drugs and the curative operations of nature. It may be said of him in his own words when speaking of Sydenham, 'that he rather sought for theory to connect his facts, than for facts to support his theory.'

In the later years of his life arose the controversy on the Brunonian system (see BROWN, JOHN, M.D.), which system Cullen bitterly opposed. Brown's specious division of diseases into sthenic and asthenic was obviously a deduction from Cullen's theories of nerve influence, and was only one instance out of many where a reputation was built on ideas borrowed from Cullen.

Cullen died on 5th February 1790 at his small estate of Ormiston Hill, having nearly completed his seventy-ninth year, and having been actively engaged in teaching and consulting practice till within a few months of his death. Cullen's most important works are *First Lines of the Practice of Physic* (Edin. 1777), *Synopsis Nosologiae Methodicae* (1785), *Institutions of Medicine* (1777), *A Treatise on the Materia Medica* (1789). See Biography, vol. i. by Dr John Thomson (1832), vol. ii. by Cullen's son and Dr David Craigie (1859), also an article by Sir W. Hamilton in the *Edinburgh Review* (1831).

Cullera, a town and port of Spain, near the mouth of the Júcar, 25 miles SSE. of Valencia. It exports rice, pistachio-nuts, oranges, wine, and oil. Pop. 11,050.

Culloden, or DRUMMOSSIE MUIR, a broad flat sandstone ridge, 300 to 500 feet high, 6 miles ENE. of Inverness. Planting and culture have changed its aspect much since 16th April 1746, when it was the scene of the total rout of 5000 Highlanders under Prince Charles Edward by 12,000 regulars under the Duke of Cumberland. Since 1881, a cairn, 20 feet in height, with an inscription, marks the spot where the battle was fiercest, and where many of the slain lie buried. Within 2 miles stands Culloden House, the seat of Duncan Forbes and his descendants.

Culm, a kind of impure Anthracite (q.v.). In some districts the culm obtained from the pits in a broken and crumbling condition is used as fuel, being made up into balls, with one-third of its bulk of wet viscid clay. It burns without flame, producing a strong and steady heat, well adapted for cooking (see BRIQUETTES). The term *Culm-measures* is applied to the carboniferous strata of Devonshire, on account of the workings for culm near Bideford, and other places.

Culm, the peculiar cylindrical hollow and jointed stem of Grasses (q.v.).

Culmination, an astronomical term, signifying the passage of a star across the meridian. The star is then at the highest point (*culmen*) of its course; hence the name. The sun culminates at mid-day, or twelve o'clock, apparent solar time—which seldom agrees exactly with mean time, as shown by a watch or clock. The full moon culminates at midnight.

Culina. See KALNA.

Culpa simply means fault (generally the omission of some act) which leads to legal liability for the immediate consequences. It may arise under a contract, especially where many of the obligations of the parties are left to implication—e.g. in the contract of carriage of passengers; or from the mere relative position of parties, as where a member of the public, or a neighbour, is injured by the negligent use of property. The distinction between culpa and breach of contract, while theoretically clear, is practically difficult; and accordingly the opinion of a jury is constantly required to ascertain whether fault has been committed in the execution of a contract.

Culpable Homicide. See HOMICIDE, and MURDER.

Culpeper, JOHN. See COLEPEPER.

Culpeper, NICHOLAS, was born in London in 1616, and after studies at Cambridge and elsewhere, started in 1640 to practise astrology and physic in Spitalfields. In 1649 he published an English translation of the College of Physicians' *Pharmacopœia* under the title *A Physical Directory, or a Translation of the London Dispensatory*, renamed in 1654 as *Pharmacopœia Londinensis, or the London Dispensatory*. This infringement upon a close monopoly, together with his sturdy and uncompromising support of Puritanism and the parliament, brought Culpeper many enemies and much obloquy. In 1653 he published *The English Physician Enlarged*. Both books had an enormous sale, and both are included in Dr Gordon's collective edition of his Works (4 vols. 1802). Culpeper wrote numerous other books, many of which were left unprinted, and died worn out before his time, 10th January 1654.

Culpeper, SIR THOMAS, was born of good Kentish family in 1578. He studied at Hart Hall, Oxford, and at one of the Inns of Court, next bought Leeds Castle in Kent, where, or at Greenway Court, near Hollingbourn, he mostly lived till his death, which took place in 1602. He was knighted by James I. in 1619. His *Tract against the high rate of Usury*, published in 1621, contended for the reduction of interest to six per cent.—His third son, SIR THOMAS CULPEPER, born in 1620, made his studies at University College, Oxford, and after making the grand tour, and being knighted soon after the Restoration, retired to his estate of Greenway Court, where he died in 1697. Besides editing and prefacing his father's treatise on exorbitant usury in 1668, he himself published many pamphlets on the same subject, repeating his father's arguments. He wrote also *Essays or Moral Discourses on several Subjects* (1655 and 1671).

Culross, a pretty, old-world village in the detached portion of Perthshire, on the north shore of the Firth of Forth, 7 miles W. by S. of Dunfermline. With memories of St Serf and St Kentigern, James VI., and the Elgin and Dundonald families, it has remains of a Cistercian abbey (1217), but has lost its manufacture of 'girdles,' its salt-works, shipping, and submarine coal-mines. A royal burgh since 1588, it unites with Stirling and three

other towns to return one member to parliament. Pop. 373. See Beveridge's *Culross and Tulliallan* (1885).

Cultivated Plants. That the history of material progress is directly connected with and measured by man's increasing utilisation of the vegetable and animal, no less than of the mineral world, is an idea of common experience, which the researches of archaeologists in all parts of the world have amply confirmed. The whole subject forms, indeed, one of the most fascinating aspects of the history of civilisation. Primitive man, acquiring his acquaintance with useful plants by slow and often bitter individual experience at the very margin of subsistence, offers a striking contrast with the experimental organiser of new and in every sense remotely productive cultures like that of the cinchona-tree in the Himalayas,—a contrast which spans the whole range alike of the practical resources and the scientific culture of the human race.

Without speculation as to the precise steps by which man passed from the hunting or merely pastoral to the agricultural state, we find positive evidence of the existence of agriculture long before written records. Thus, though the 'kitchen-middens' of northern countries contain no trace of cultivated plants, the deposits of Swiss lake-dwellings have yielded remains of fruits, of cereal and other seeds, and of linen fabrics, showing the existence of a considerable agriculture before the use of metals. Ancient traditions and ceremonials of China also bear witness to the remoteness of cultivation there. The earliest Egyptian picture-writings and the greater number of cultivated species have arisen in that central cradle of civilisation which may be broadly marked off by drawing lines from the delta of the Nile to the head of the Persian Gulf, and from the Dardanelles to the Caspian—i.e. between 30° and 40° lat. From this region the majority of European plants are derived. Another great centre of ancient agriculture, however, is China; while the third is intertropical America, where the ancient Mexicans and Peruvians practised the culture of not a few plants, of which some have become almost cosmopolitan since the epoch-making voyage of Columbus.

Since the rise of modern botany (see BOTANY), our knowledge of species at least possibly useful has been greatly extended, yet there seems little risk of displacement of the established cereals, fruit-trees, &c., since these have the advantage of an enormous past of artificial selection, which has in many cases practically transformed them into new species, apparently distinct from their wild congeners, and incapable of continued existence in the uncultivated state—e.g. wheat, barley, maize, pea, sugar-cane, yam, &c., and probably also bean, tobacco, manioc, &c. Moreover, such long cultivated plants usually exhibit greater variability than naturally wild species, and thus in every way new cultures tend to be unremunerative. Hence the majority of species of primary nutritive importance to man at present are among those which have been in cultivation for the past 2000 years; and the progress which is now being made is essentially on lines which merely supplement these; the newer plants, cultivated for less than 2000 years, being, according to De Candolle, chiefly artificial fodders, which the ancients scarcely knew; then bulbs, vegetables, medicinal plants (cinchona); plants with edible fruits or nutritious seeds (buckwheat), or aromatic seeds (coffee). Here, of course, the demand for variations in food and drink, for narcotics and medicines, for textiles and timber, all combine towards progress; in most of these the demand is at bottom more largely æsthetic than utilitarian,

while this becomes exclusive in the newest but extending department of flower gardening.

See the articles AGRICULTURE, HORTICULTURE, FRUIT, PASTURE, MEDICINAL PLANTS, &c.; those on special plants—e.g. BARLEY, COCA, DATE, MAIZE, &c.; also De Candolle, *Origin of Cultivated Plants* (Inter. Sc. Series, 1884); and Hehn's *Wanderings of Plants and Animals* (1886).

Cultivator, a farm implement. See GRUBBER.

Culverin, one of the earlier forms of Cannon (q.v.), of great length, generally an 18-pounder, weighing 50 cwt.; the *demii-culverin* being a 9-pounder, weighing 30 cwt.

Culver's Root, the rhizome of *Veronica virginica*, used medicinally as *radix leptandra* of U.S. Pharmacopœia.

Culvert is the name given to an arched channel of masonry for the conveyance of water underground or beneath an embankment.

Culverwel, NATHANAEL, one of the Cambridge Platonists, was born in Middlesex, and entered Emmanuel College in 1633. He graduated B.A. in 1636, M.A. in 1640, was elected fellow in 1642, and died not later than 1651. In 1652 was published *An Elegant and Learned Discourse of the Light of Nature*, with several other treatises—viz. the Schism, the Act of Oblivion, the Child's Return, the Panting Soul, Mount Ebal, the White Stone; *Spiritual Optics*; and the *Worth of Souls*. An edition of the *Light of Nature* was issued in 1857, edited by Dr John Brown of Edinburgh, with a critical essay by Principal Cairns. It is a treatise of great power and learning, written in a vivid and vigorous style, and is a work not unworthy of the college that produced Cudworth, Whichcote, and John Smith. See Tulloch's *Rational Theology*, vol. ii. (1874), pp. 410-26.

Cumæ, an ancient city on the coast of Campania, founded conjointly by colonists from Chalcis in Eubœa, and from the Æolian town of Cyme in Asia Minor. The date of its foundation is uncertain, but according to Strabo it was the earliest of all the Greek settlements either in Italy or Sicily. It soon attained to wealth and power, built several harbours or port-towns of its own, kept a tolerably large fleet, extended its influence over the native tribes of the neighbouring territories, planted colonies in Italy and Sicily, at Puteoli, Neapolis, and Zancle (Messina). Spite of attacks from the Etruscans and Umbrians without, and dissensions within, for the two hundred years before 500 B.C. it was the most important and civilised city in Southern Italy. In 474 its ally, Hieron, king of Syracuse, defeated the combined fleets of the Etruscans and Carthaginians, who had attacked it by sea. Cumæ at length lost its independence (417 B.C.) when it was conquered by the Samnites, who killed or enslaved most of the citizens. It ultimately became a Roman municipium and colony, but continued to decline. It re-assumed a momentary importance during the wars of Belisarius and Narses. Its strong fortress, garrisoned by the Goths, was the last place in Italy that held out against the Byzantine army. Few remains of the ancient city exist.—Cumæ is famous as the residence of the Sibyl (q.v.), whose cave was identified with one of the many subterranean passages in the rock on which the citadel stood. Most of these are now choked up.

Cumana, a town of the Venezuelan state of Bermudez, on the Manzanares, a mile above its mouth, where the port of Puerto Sucre lies on the Gulf of Cariaco. It has a national college, and some export trade, but is chiefly of interest as the oldest European town on the South American mainland, having been founded by Christopher Columbus's son Diego as New Toledo in 1521. It

has suffered much from earthquakes, and was almost entirely destroyed in 1853. Pop. (1881) 12,051.

Cumania is the name of a region in Central Hungary divided into *Great Cumania*, east of the Theiss, and *Little Cumania*, between the Danube and the Theiss, now incorporated in the adjoining Hungarian provinces. The inhabitants, the Cumans, are the descendants of a race of nomad invaders of the Turkish stock, who forced their way into Hungary from beyond the Volga in the 11th century. They long held their own in alternate alliance and war with the surrounding states. They maintained their heathenism and their barbarous customs, till in 1278 a crusade was proclaimed against them by Pope Nicholas IV., and they were compelled to accept Christianity and adopt the ways of their Magyar neighbours. They are now wholly Magyarised.

Cumberland, a Border county of England, washed on the W. by the Irish Sea and the Solway Firth, and elsewhere bounded by Dumfries and Roxburgh shires, Northumberland, Durham, Westmoreland, and Lancashire. Eleventh in size of the English counties, it has a maximum length of 75 miles, a maximum breadth of 45, a coast-line of 75, and an area of 1564 sq. m. The surface is mountainous in the south-west and east; the middle consists of hills, valleys, and elevated ridges; and the north and north-west districts, including the vale of Carlisle, are low, flat, or gently undulated. The mountains in the south-west are high, rugged, and sterile, with deep and narrow valleys, lakes, rivers, waterfalls, and woodlands. The chief mountains are Scaw Fell Pike (3210 feet), Scaw Fell (3162), Helvellyn (3118), Skiddaw (3058), Bow Fell (2960), and Cross Fell (2892). The largest lakes are Ullswater, Derwentwater, Bassenthwaite, Thirlmere, Buttermere, Wastwater, and Ennerdale. Six of the chief waterfalls are 60 to 156 feet high. The chief rivers are the Eden, the Esk, and the Derwent. The Lancaster and Carlisle railway route from London to Edinburgh crosses the north-east part of Cumberland.

The Lake district, or nearly the south-west half of Cumberland, consists of Silurian slates, with protrusions of granite and trap rocks, and with New Red sandstone along the coast south of St Bees Head. In the north is a semicircular strip of carboniferous limestone; then follow strips of coal strata and Permian rocks; then the new red sandstone plain of Carlisle, with carboniferous limestone on the north-east, including a trap-dike 30 miles long. Cumberland abounds in mineral wealth—silver, copper, lead, iron, plumbago, gypsum, limestone, coal, slates, marbles, marl, and several of the rarer minerals.

In the mountainous parts the climate is wet and variable, especially from July to October; on the coast it is mild. There is an annual rainfall of 50 inches at Whitehaven, and of 59 at Keswick; while at Styhead Pass, at an altitude of 1077 feet, the rainfall has been as much as 243·98 inches. Half of the cultivated soil consists of dry loam. Much of the subsoil is wet clay. The chief crops are wheat, barley, oats, turnips, and potatoes. There are many small dairies. Sheep and cattle are reared in the mountains. The estates are generally small, and farmed by the owners, or held under the lords of the manors by customary tenure. Many of the small proprietors, or 'statesmen,' have had their lands in their families for centuries, and have a high spirit of independence. There are manufactures of woollens—much being domestic—cottons, linens, earthenware, and glass. The chief towns are Carlisle, Cockermouth, Whitehaven, Workington, Maryport, Wigton, Penrith, Keswick,

Egremont. Under the Distribution of Seats Act, 1885, Cumberland returns one member for each of the four divisions, North or Eskdale, Mid or Penrith, Cockermouth, and West or Egremont. Pop. (1801) 117,230; (1841) 178,038; (1871) 220,253; (1881) 250,647. Near Keswick and Karkoswald are two fine stone circles; and many Roman relics have been found, such as altars, coins, and inscriptions. For centuries part of Cumbria or Strathclyde, the present county was finally annexed to England in 1157. For three hundred years prior to the union of the crowns, it was the constant scene of war and devastation, from incursions of the English and Scotch; and it suffered again in both the '15 and the '45. Cumberland had formerly several monasteries and hospitals; and on the Border, many towers or peel-houses; and it has still some fine old churches. See BORDERS, LAKE SCHOOL.

Cumberland, a river, rises in Kentucky, flows into Tennessee, and returning to Kentucky, enters the Ohio at Smithland, after a course of about 650 miles, of which nearly 200 are navigable for steamboats.—For Cumberland Mountain, see APPALACHIANS.

Cumberland, capital of Alleghany county, Maryland, on the Potomac River, 178 miles W. by N. of Baltimore by rail. It is a canal terminus and an important railway centre, and has manufactures of brick, cement, flour, and leather, and an extensive trade in coal. Pop. (1880) 10,693.

Cumberland, DR RICHARD, was born in London, July 15, 1631. Educated at St Paul's School and Magdalene College, Cambridge, he was preferred to the rectory of Brampton, Northamptonshire, in 1658; in 1667 to the living of All Hallows, Stamford; and in 1691 to the bishopric of Peterborough. Cumberland was a man of great acquirements, and of sincere and simple piety; his frequent saying, 'a man had better wear out than rust out,' explains his unusually high idea of episcopal duty. He wrote several works, of which one is still read, his *Inquiry into the Laws of Nature*, written in reply to Hobbes, and remarkable as placing the foundation of morality on a utilitarian basis. His *Essay on Jewish Weights and Measures* was dedicated to his old college friend Pepys, as president of the Royal Society. As an instance of Cumberland's insatiable thirst for knowledge, it is mentioned that he learned Coptic after the age of eighty-three. He died October 9, 1718.

Cumberland, RICHARD, a dramatic writer and essayist, was born on the 19th February 1732, in the lodge of Trinity College, Cambridge. He was the great-grandson of Bishop Cumberland, and grandson, by the mother's side, of Dr Richard Bentley. From Bury St Edmunds and Westminster, where he was contemporary with Cowper, Churchill, and Warren Hastings, he passed to Trinity College, Cambridge, and here was elected to a fellowship at twenty. Becoming private secretary to Lord Halifax, he gave up his intention of entering the church, and, after passing through several subordinate offices, was appointed secretary to the Board of Trade. He held that office after his return from an unfortunate secret mission to Spain (1780), which cost him as much as £5000, a sum that ministers refused to reimburse, when the Board was suppressed. Having obtained a compensation allowance of about half his salary, Cumberland retired to Tunbridge Wells, where he devoted himself to literature, and wrote incessantly farces, tragedies, comedies, pamphlets, essays, and novels, two at least of merit, *Arundel* and *Henry*. Many of his comedies were successful at the time of their appearance, although they have

not kept possession of the stage. Among them may here be named *The West Indian*, *The Brothers*, *The Fashionable Lover*, *The Jew*, and *The Wheel of Fortune*. Cumberland is alluded to in Goldsmith's *Retaliation* with not unkindly satire as 'the Terence of England, the mender of hearts;' in Sheridan's *Critic* he is gibbeted as 'Sir Fretful Plagiary.' Cumberland's essays and translations from the Greek poets are long forgotten. He died at Tunbridge Wells, 7th May 1811. His inaccurate Memoirs of himself were published in 1807.

Cumberland, WILLIAM AUGUSTUS, DUKE OF, second son of George II., was born in 1721. He adopted a military career, was wounded at Dettingen in 1743, and defeated, not ingloriously, at Fontenoy, by Marshal Saxe, in 1745. He was next sent to crush the Young Pretender's rebellion, which he did effectually at Culloden (1746); and by a series of severe measures against the broken and dispirited Highlanders he earned for himself the lasting title of 'the Butcher,' to set off against his reward of £25,000 a year and the thanks of parliament. In 1747 he was defeated by Saxe at Laffeld, and in 1757 had to surrender and disarm his army at Kloster-Zeven, after which he retired into private life, and died in 1765. Those who feel interest in his career may read his *Life* (1776) and *General Orders of 1745-47* (1876).—For other dukes and earls of Cumberland, see HANOVER, and CLIFFORD.

Cumberland Island (so called) is a peninsula of Baffin Land, extending into Davis Strait.

Cumberland Presbyterians, a religious denomination which sprang up in 1810 in the state of Kentucky, in consequence of a dispute between the presbytery of Cumberland in that state, and the Kentucky Synod of the Presbyterian Church in America, concerning the ordination of persons who had not passed through the usual educational curriculum, but whose services the presbytery regarded as demanded for the ministry by the exigencies of the times. In 1887 this church had 26 synods, 1538 ministers, 150,000 members, and several colleges and seminaries. Their form of government is presbyterian, though they have added a system of itinerating like the Methodists. In doctrine they approach Arminianism, denying unconditional election and predestination, and they believe in the universality of the atonement.

Cumbræ, BIG or GREAT, an island of Bute-shire, in the Firth of Clyde, 2½ miles E. of Bute at the narrowest, and 1½ mile WSW. of Largs. With the shape of a shark's tooth, it is 3½ miles long, 2 broad, 10½ in circumference, and 5 sq. m. in area. It rises to a height of 417 feet, and consists of Old Red sandstone, with wall-like trap-dykes intersecting it. The Marquis of Bute is sole proprietor. Millport, on the south shore, 19 miles SSW. of Greenock (*vid* Wemyss Bay), is a crowded resort in summer. Pop. (1801) 506; (1881) 1856, of whom 1740 were in Millport.—LITTLE CUMBRÆ, 1½ mile SSW. of Millport, is barely 1 sq. m. in area. It rises 409 feet, and has a lighthouse (1826). Pop. 23.

Cumbria. See CAMBRIA and STRATHCLYDE.

Cummin, or CUMIN (*Cuminum*), a genus of Umbelliferae, containing only one known species (*C. cyminum*), common in Egypt and the neighbouring countries, sometimes as an annual weed, but more frequently in cultivation, as also in southern Europe and India. It is referred to in Scripture (as in Matt. xxiii. 23). The fruit-lobes separate in the way characteristic of the order, and are thus popularly called seeds; their odour and properties resemble those of Caraway (q.v.),

but are stronger, and therefore to some palates more pleasant. It is employed as a carminative flavouring in many parts of the world; but its strictly medicinal use (as in plasters) is now chiefly confined to veterinary practice. In Germany, it is often put into bread; in Holland, sometimes into cheese. It contains a peculiar volatile oil (*Oil of Cummin*). Cummin-seed is brought to Britain mostly from Sicily and Malta.—The fruit of *Lagocchia cuminoides*, another umbelliferous plant, a native of the Levant, is similar in its qualities and uses to that of cummin. The Black Cummin of the ancients is sometimes identified as a species of *Nigella* (q.v.).

Cumming, CONSTANCE FREDERIKA GORDON, a well-known traveller, was born 24th May 1837, and was the sister of the lion-hunter (see below). She has travelled extensively, having resided for two years in Ceylon, and two in Fiji. She has also visited Tahiti, China, Japan, California, Hawaii, New Zealand, and Australia, and has written various sprightly and entertaining volumes of travel, including *From the Hebrides to the Himalayas* (1876); *At Home in Fiji* (1881); *A Lady's Cruise in a French Man-of-war* (1882); *Fire Fountains—Hawaii* (1883); *Wanderings in China* (1885).

Cumming, JOHN, divine and author, was born in Fintry parish, Aberdeenshire, 10th November 1807. He was educated at King's College, Aberdeen, where he took his degree of M.A. in 1827, and in 1832 was ordained to the Scotch Church, Crown Court, Covent Garden, London, where he preached with great popularity and success till 1879. Edinburgh University gave him the degree of D.D. in 1844. He was active in philanthropic projects, and as a controversialist and lecturer both against the party that formed the Scotch Free Church and in the 'anti-Popery' cause; but his celebrity was chiefly due to his writings on the interpretation of prophecy. His audacity in this perilous enterprise drew upon him much ridicule. In 1868 he asked the pope if he might attend the Ecumenical Council, but his application was declined through Archbishop Manning. After some years of ill-health, Cumming died 5th July 1881. His works number over a hundred various publications. Among them are *Apocalyptic Sketches* (three series, 1848–50), *Prophetic Studies* (1850), *Signs of the Times* (1854), *The Millennial Rest* (1862), *Ritualism the Highway to Rome* (1867), *The Sounding of the Last Trumpet* (1867), and *The Seventh Vial* (1870).

Cumming, ROUALEYN-GEORGE GORDON, the African lion-hunter and the second son of Sir William Gordon Gordon-Cumming, was born 15th March 1820, and was educated at Eton. He became a cornet in the Madras Cavalry in 1838, served for a time in Canada, and joined the Cape Mounted Rifles in 1843; but he soon resigned his commission, and, till his return to England in 1848, engaged in those famous hunting exploits, narrated in his *Five Years of a Hunter's Life* (1850), of which he issued a condensed edition, entitled *The Lion-hunter of South Africa* (1858). He died at his residence, Fort Augustus, 24th March 1866.

Cummins, MARIA SUSANNA, American novelist, born at Salem, Massachusetts, April 9, 1827, began to write in 1850, contributing presently to the *Atlantic Monthly* and other magazines. Her first novel, *The Lamplighter* (1854), had a phenomenal sale, 40,000 copies being sold in two months; its entire sale in America alone has exceeded 120,000 copies. Her other books include *Mabel Vaughan* (1857), *El Fureidis* (1860), and *Haunted Hearts* (1864). She died at Dorchester, October 1, 1866.

Cumnock, OLD, a town of Ayrshire, on Lugar Water, 18 miles by rail E. of Ayr, and 43 NW. of Dumfries. The manufacture of wooden snuff-boxes was many years since transferred to Mauchline, and mining is now the chief industry. The Covenanted 'prophet,' Peden (1626–86), lies in the churchyard. Dumfries House, a seat of the Marquis of Bute, is 2 miles to the west. Pop. 3345.—**NEW CUMNOCK**, on the Nith, 5½ miles SE. of Old Cumnock, has 1265 inhabitants.

Cumulative Voting. See REPRESENTATION.

Cunard, SIR SAMUEL, was born 21st November 1787 at Halifax, Nova Scotia, where his father, a Philadelphia merchant, had settled. Becoming early a successful merchant and shipowner, Cunard came to England in 1838, joined with George Burns, Glasgow, and David M'Iver, Liverpool, in founding (1839) the British and North American Royal Mail Steam Packet Company, and obtained a contract from the British government for the mail service between Liverpool and Halifax, Boston, and Quebec. The first passage was that of the *Britannia* in 1840, the time occupied being fourteen days eight hours. Iron steamers were first used in 1855, and paddle-wheels gave way entirely to the screw after 1862. From its small but successful beginning, Cunard's undertaking soon developed into one of the vastest of private commercial concerns. In 1878 it was made into a joint-stock company. Created a baronet in 1859, Cunard died at London, 28th April 1865.

Cunaxa, in Babylonia, east of the Euphrates, about 60 miles N. of Babylon, noted for the battle (401 B.C.) between Cyrus the younger and his brother Artaxerxes Mnemon, in which the former was killed.

Cundinamarca, a central department of Colombia, extending east to Venezuela. It is the second largest department of the republic, with an area of 8500 sq. m., excluding the territory to the south-east of the Meta, which is about as large as Italy. The population was officially estimated in 1881 at 539,000. The western part is mountainous, with fertile valleys and plateaus; in the east are vast plains. It is well wooded, and rich in minerals. The capital is Bogotá (q.v.), also capital of the republic.

Cuneiform, Cuneatic, Wedge-shaped, Arrow-headed (Fr. *lettre-clou*, Ger. *keilförmig*), are terms for a certain form of writing, of which the component parts resemble a wedge. It was used by the ancient peoples of Akkad, Babylonia, Assyria, Armenia, Elam, and Persia; and was inscribed upon stone, bronze, iron, glass, and clay. Cuneiform inscriptions were chiselled upon stone and iron, but they were impressed upon soft clay with a pointed stylus having three unequal facets; the smallest to make the fine wedge of the cuneiform signs, the middle-sized to make the thicker wedges, and the largest to make the outer and thick wedges of the characters. The first date that can be assigned to the use of cuneiform writing is about 3800 B.C., and its use was continued until after the birth of Christ. The earliest inscription at present known is that inscribed upon the porphyry whorl in the time of Sargon of Agade; the latest is a tablet preserved at Munich, which may have been written about 83 A.D. Cuneiform writing was first used in Mesopotamia, and from thence it spread to Persia and to the districts north of Nineveh. For nearly 1600 years after its extinction its very existence was forgotten. The immense ruins found all over that ancient kingdom, and especially those of ancient Persepolis, had at all times attracted the attention of eastern travellers; still no one seems to have dreamed that those strange wedges which com-

pletely covered some of them could have any meaning. It was Garcia de Sylva Figueroa, ambassador of Philip III. of Spain, who, on a visit to Persepolis in 1618, first became possessed with the firm conviction that these signs must be inscriptions in some lost writing and, perhaps, language, and had a line of them copied. Amongst subsequent travellers whose attention was attracted to the subject, Chardin, after his return to Europe in 1674, published three complete groups of cuneiforms, copied by himself at Persepolis, together with a comparatively long and minute account of the mysterious character. He likewise declared it to be 'writing and no hieroglyphs: the rest, however, will always be unknown.' Michaux, a French botanist, sent, in 1782, a boundary stone, found at Bagdad, to Paris, covered with inscriptions. Ever since, the materials for the investigation of a subject the high importance of which by that time was fully recognised have been rapidly accumulating. Sir H. Jones, Ker Porter, Robert Stewart, Sir W. Ouseley, Bellino, Dr Schultz—up to Rich and Botta, Flandin, Rouet, Layard, Oppert, Smith, Rassam, Budge, and, above all, Rawlinson, each in his turn brought back more or less valuable materials from his eastern travels; and, naturally enough, those explorers were among the foremost to engage in the study of the records they had brought to light.

Now that we are able to explain so much of these inscriptions, it is highly interesting and instructive to notice the opinions first entertained of them by the wise and learned in Europe. In the *Transactions of the Royal Society of June 1693*, they first appeared from a copy made by Flowers, and they are held to be 'the ancient writing of the Gaures or Gebres.' Thomas Hyde, the eminent Orientalist, declared them, in his learned work on the religion of the ancient Persians (1700), to be nothing more or less than idle fancies of the architect, who endeavoured to show how many different characters a certain peculiar stroke in different combinations could furnish. Witte, in Rostock, saw in them the destructive work of generations upon generations of worms. Generally, they were pronounced to be talismanic signs, mysterious formulæ of priests, astrological symbols, charms which, if properly read and used, would open immense vaults full of gold and pearls—an opinion widely diffused among the native savants. The next step was to see in them a species of revealed digital language, such as the Almighty had first used to Adam. Liechtenstein read in some of them certain passages from the *Koran*, written in Kufic, the ancient Arabic character; in others, a record of Tamerlane; and was only surprised that others should not have found this, the easiest and clearest reading, long before him. Kämpfer was not quite sure whether they were Chinese or Hebrew characters. That they were Runes, Oghams, Samaritan, or Greek characters, were some of the soberest explanations.

It was Karsten Niebuhr who first showed the way, to the more sensible portion of the learned, out of this labyrinth of absurdities. Without attempting to read the character itself, he first of all established three distinct cuneiform alphabets instead of one, the letters of which seemed to outnumber those of all other languages together. The threefold inscriptions found at Persepolis he rightly took to be transcripts of the same text in three alphabets, in a hitherto unknown language. Tychsen of Rostock (1798), and Minter of Copenhagen (1800), affirmed and further developed this conjecture. The latter went so far as to divide the characters and inscriptions into alphabetical, syllabic, and monogrammatical, and to assume two different languages—Zend for inscriptions of a religious, Pehlvi for those of a political character.

The real and final discovery, however, is due to Grotefend of Hanover, and dates from 1802. On the 7th of September of that year he laid the first cuneiform alphabet, with its equivalents, before the Academy of Göttingen—strangely enough, in the very same sitting in which Heyne gave an account of the first reading of hieroglyphs. The process by which Grotefend arrived at that wonderful result is so supremely interesting, that we cannot omit to sketch it briefly. He fixed upon a Persepolitan inscription of what was called the first class, and counted in it thirty promiscuously recurring groups or combinations of cuneiforms. These groups he concluded to be letters, and not words, as a syllabary of thirty words could not be thought of in any language. Then, again, a certain oblique wedge, evidently a sign of division, which stood after three, four, five, up to eight or nine such groups or letters, must show the beginning or end, not of a phrase, but of a word. Tychsen and Minter had already pointed out a certain combination of seven characters as signifying the royal title. Grotefend adopted this opinion. The word occurred here and there in the text, and after the first words of most of the inscriptions, twice; the second time with an appendage, which he concluded to be the termination of the genitive plural, and he translated these two words, without regard to their phonetic value, 'King of Kings.' He then, in comparing the words preceding the royal titles in two tablets, found them repeated in what he assumed to be a filial relation; thus: There were three distinct groups, words, or names, which we will call X, D, and H, and this is how they occurred: (1) X, King of Kings, son of D, King of Kings; (2) D, King of Kings, son of H; but the (3) H was *not* followed by the word King. H, therefore, must have been the founder of the dynasty. Now the names themselves had to be found. Grotefend, unlike his predecessors, had recourse not to philology, but to archaeology and history. The inscriptions in question were by that time proved to belong to the Achaemenian dynasty, founded by Hystaspes = group H. He was followed by Darius, 'King of Kings, son of Hystaspes,' or Darius Hystaspes = group D; he, again, by Xerxes, King of Kings, son of Darius, King of Kings = group X—and the problem was solved. It could not have been Cyrus and Cambyses, as the groups did not begin with the same signs (C); nor Cyrus and Artaxerxes, the first being too short for the group, the second too long—it could only be Darius, Xerxes, Hystaspes—of course in the orthography of their, not of our time; and wherever in these names the same letters recurred, they were expressed by the same combinations of signs. A further proof of the correctness of the reading was furnished by a vase in Venice, bearing a cuneiform and a hieroglyphical inscription, which were both read at the same time independently: 'Xerxes.' Innumerable difficulties, however, remained, and remain up to this moment. Grotefend had, after all, only read—and not altogether correctly—three names, which did not contain more than twelve letters—the rest being mere conjecture—and there were many more in this alphabet. The other two alphabets, with an infinite variety of letters, had hardly been properly approached yet. Moreover, the discovery of Grotefend was in itself so startling, so extraordinary and bold, that no one ventured to follow it up for the next twenty years, when H. Martin found the grammatical flexions of the plural and genitive case. We cannot now specify his further discoveries, or those of Rask, Burnouf, Lassen, Westergaard, Beer, Jacquet, and others who followed; we will only say that they mostly secured for themselves fame and name by rectifying or fixing one or two letters. The last and greatest of investigators of this first alphabet

is Rawlinson, who not only first copied, but also read, the gigantic Behistun inscription—containing more than 1000 lines—of which more anon.

Inscriptions in the Persian cuneiform character are mostly found in three parallel columns, and are then translations of each other in different alphabets and languages, called respectively Persian, Median, and Babylonian; the Achæmenian kings being obliged to make their decrees intelligible to the three principal nations under their sway, as in our days the Shah of Persia would use the Persian, Turkish, and Arabic languages, in order that he might be understood in Bagdad and Teheran.

The first of the three, the Persian, consists of thirty-nine to forty-four letters, and is the most recent, the most ancient being the Babylonian. It is distinguished by the oblique stroke which divides its words. Its letters are composed of not more than five strokes or wedges placed side by side horizontally or perpendicularly, or both, but never—with one exception—crossing each other. The language is pronounced by all investigators to be as near Zend (q.v.) as possible, and to be the mother-language of modern Persian. It is only twice found by itself; all the other inscriptions are trilingual. The time of its use is confined to the years 570–370 B.C. The oldest instance of its employment is an inscription of Cyrus the Great at Pasargadæ; the most recent, that of Artaxerxes Ochus at Persepolis. The most important is that of Darius Hystaspes, in the great inscription of Behistun (q.v.), which contains, besides genealogical records, a description of the extent of his power, the leading incidents of his reign, prayers to Ormuzd and the angels, and reference to the building of the palaces. Most of these inscriptions occur at Persepolis, Behistun, Naksh-i-Rustam, and Hamadan.

The second kind is called the Median, because it takes the second place in the trilingual inscriptions, under the conquering Persians, but over the conquered Assyrians, and as the Medes stood somewhat in that relation to these two nations, that name was selected. Another name, 'Scythic,' has been proposed, or, by way of compromise, 'Medo-Scythic,' and the language—supposed to have been spoken by those innumerable Tartaro-Finnic tribes which occupied the centre of Asia—has been pronounced to be a Turanian dialect. But the process of constructing out of such slender elements as Samojed and Ostiak words, a so-called 'Scythic,' is somewhat similar to the attempt of reconstructing Sanskrit from some detached and very doubtful French and English words. These inscriptions never occur by themselves (one instance again excepted), and being translations of the Persian records, about ninety names have been ascertained, and an alphabet of about one hundred characters—combinations of a syllabic nature—has been established. The principal investigators of this character are Westergaard, De Sauley, Hincks, Norris, and Oppert. Gobineau holds the language to be Huzvareh, a mixture of Iranian and Semitic.

The third and most important is the Babylonian portion of the cuneiforms. The trilingual records gave the first clue to the deciphering of this character; but many original documents, more than three thousand years older, have since been found in Babylon, Nineveh, and other places near the Euphrates and Tigris, and even in Egypt. On one occasion, the Asiatic Society submitted a cylinder of Tiglath-pileser to four prominent investigators of the subject, and they independently read it nearly alike, with the exception of the proper names, where they widely differed. As a proof of the enormous importance of this character for history, grammar, law, mythology, archaeology, and antiquities generally, we name some of the

records which Rawlinson began to publish (now in progress): Babylonian Legends, such as the Fight between Marduk and Tiamat, the Descent of Ishtar into Hades (2000–1500 B.C.); Bricks from Kilelishergat of the early Kings of Assyria (1350–1100 B.C.), in a character much complicated; Annals of Tiglath-pileser I. (1120 B.C.); Annals of Assur-nasir-pal, of Shalmaneser I. and II., Sargon, Sennacherib, Assur-bani-pal, son of Esarhaddon; Inscriptions of Nebuchadnezzar I. and II.; Cylinders containing the name of Belshazzar, &c.; besides syllabaries, vocabularies, mathematical and astronomical tablets, calendars, and a selection from the mythological tablets.

In order to give the reader some idea of the appearance of the cuneiform character, we subjoin the name of Darius, written in the Persian, Scythic, and Babylonian characters.

𐎠 𐎡 𐎢 𐎣 𐎤 𐎥 𐎦 𐎧 𐎨 𐎩 𐎪 𐎫 𐎬 𐎭 𐎮 𐎯 𐎰 𐎱 𐎲 𐎳 𐎴 𐎵 𐎶 𐎷 𐎸 𐎹 𐎺 𐎻 𐎼 𐎽 𐎾 𐎿

Babylonian.

The cuneiform signs were originally pictures of objects. It appears that they were first drawn in outline upon some vegetable substance, called in the native documents *likhusi*. Whether the supply of this material failed it is impossible to say, but it is quite certain that at a very early period in the history of Babylonia, clay was adopted as a substance for writing upon. On substances like papyrus and leather it is quite easy to draw in outline a picture of any object; but it became more difficult to do this when clay was used, because the outlines of the object represented had to be pressed into it. The necessary result of this was that the shapes of the objects became altered. Thus a circle (1) represented the sun, but when inscribed upon clay it became 2; and a star (3) became 4: in process of time, as scribes became busier, these signs were represented by 5 and 6 respectively.

The use of clay as a writing material completely modified the shape of nearly every character in the cuneiform syllabary. The signs inscribed upon stones of the early empire are most complex, and in many of them it is difficult to see what object they are intended to represent. As time went on, these complex signs became simplified, and wedge after wedge was discarded, until the character was reduced to its simplest form. Lenormant, Hyde Clark, and others adopting their theory, have tried to prove that the Babylonian and Chinese signs are related. In the time of Esarhaddon and Assur-bani-pal, it became the fashion to write inscriptions in the ancient complex character, and special syllabaries of such signs were drawn up. Fragments of these are now in the British Museum. The cuneiform syllabary contains about two thousand signs of a phonetic, syllabic, and ideographic nature. Each sign originally represented an object, but no attention was paid to its ideographic signification when its

syllabic or phonetic value was employed in a word. Before the name of a king, town, city, or private person, &c., a cuneiform sign, being the ideograph for the word following, was placed; after names of places like *Bablu* (Babylon), a suffix *ki*, meaning 'earth' or 'land', was placed. It is the opinion of some that the cuneiform characters were invented by the primitive Akkadian inhabitants of Chaldaea (who spoke an agglutinative language). See the articles ASSYRIA, BABYLON.

For fuller information on this subject, see Rawlinson, *The Persian Cuneiform Inscription at Behistun* (Journal As. Soc. 1846, &c.); Grotefend, *Die Keilinschriften aus Behistun* (1854); Lassen u. Westergaard, *Ueber die Keilinschriften* (1845); Hincks, *On the First and Second Kinds of Persepolitan Writing* (Transact. Roy. Ir. Soc. 1846); Norris, *Memoir on the Sythic Version of the Behistun Inscription* (Journal As. Soc. 1853); Rawlinson, *A Commentary on the Cuneiform Inscriptions of Babylon and Assyria* (1850); and works by Benfey, Oppert, Renan, Spiegel, Schrader, Delitzsch, and others.

Cune'e, a river of Portuguese South Africa, rises on the heights which bound the interior plateau of South Africa, and after a course of 600 miles southward and westward through the province of Mossamedes, reaches the sea 60 miles north of Cape Frio. It is nearly useless for navigation, being shallow and barred by sand-banks.

Cuneo. See CONI.

Cunningham, ALLAN, poet and industrious man of letters, was born in the parish of Keir, Dumfriesshire, 7th December 1784. His father was factor or land-steward to Miller of Dalswinton, and therefore neighbour to Burns at Ellisland; and Allan, a boy of twelve, followed at the great poet's funeral. At eleven he was apprenticed to a stone-mason, but continued to give all his leisure to poring over native songs and stories. His first publications were his verse and prose contributions to Cromek's sham-antique *Remains of Nithsdale and Galloway Song* (1810). These, while they did not of course deceive the learned, or apparently even Cromek himself, procured the clever young mason the acquaintance of Hogg and Sir Walter Scott. With the latter, 'Honest Allan' was always a great favourite. He now removed to London, and became one of the best-known writers for the *London Magazine*, as well as secretary and manager in Chantrey's studio, a post which he held till Chantrey's death in 1841. Though thus busily employed all day, Cunningham maintained an indefatigable literary activity, writing tales, novels, magazine articles, poems, songs, and biographies. His best works were his *Traditional Tales of the English and Scottish Peasantry* (1822); *The Songs of Scotland, Ancient and Modern* (1825); *Lives of the Most Famous British Painters, Sculptors, and Architects* (6 vols. 1829-33); and his edition of Burns, with Life (8 vols. 1834). His *Life of Sir David Wilkie* appeared posthumously. He died in London, 30th October 1842. Cunningham was a remarkably worthy and kindly man, whose 'stalwart healthy figure and ways' pleased even Carlyle—but then he was from Dumfriesshire. As a Scotch poet, he ranks, perhaps, after James Hogg. His songs, although marred by defects in taste, mannerism, and a superabundance of ornament, have the true lyrical impulse and movement.

Of his sons, Alexander and Joseph rose in the Indian service; the former wrote many books on Indian architecture and statistics, the latter, a good *History of the Sikhs* (1849); Peter (see below) became a well-known antiquary and man of letters; Francis, also an Indian soldier, edited Marlowe, Massinger, and Ben Jonson.

Cunningham, PETER, son of Allan Cunningham the poet, was born in Pimlico, April 1, 1816. He was educated at Christ's Hospital, London,

entered the Audit Office through Peel's influence in 1834, and ultimately became chief clerk. He retired in 1860, and died at St Albans, 18th May 1869. His name is chiefly remembered by his *Handbook of London* (1849), a book stored with out-of-the-way facts, and informed with true literary flavour. He contributed largely to the literary journals, edited books for both the Shakespeare and the Percy Societies, as well as Horace Walpole's *Letters* (1857), Drummond of Hawthornden, Goldsmith, Johnson's *Lives of the Poets*, and Pope. Other books are *Modern London* (1851) and the *Story of Nell Gwynn* (1852).

Cunningham, WILLIAM, a distinguished Scotch theologian, was born at Hamilton in 1805, educated at Duns and Edinburgh, and ordained minister at Greenock in 1830. He was called to Trinity College Church, Edinburgh, in 1834, and soon became one of the foremost leaders, alike on the platform and in the pamphlet, on the 'Non-intrusionist' side in the great controversy that preceded the Disruption of 1843. He was appointed professor of Theology in the Free Church College in 1843, of Church History in 1845, and its principal on Chalmers's death in 1847. His D.D. degree was given him by Princeton in 1842. He was moderator of the Free Assembly in 1859, when he received a testimonial amounting to over £7000. He died at Edinburgh, 14th December 1861. His literary executors published from his MSS. *Historic Theology: a Review of the Principal Doctrinal Discussions in the Christian Church* (1862), *Reformers and Theology of the Reformation* (1862), and *Discussions on Church Principles* (1863). See his Life, by Rainy and Mackenzie (1871).

Cunninghamia, a genus of the Taxodium family of Coniferae (q.v.), of which the only species (*C. sinensis*) is a lofty evergreen tree of southern China and Cochin China, with sessile leathery leaves, somewhat resembling those of an Araucaria. It is too tender for the climate of Britain, save in peculiarly favourable localities.

Cup is a name for a refreshing beverage, made usually of wine, soda-water, ice, and flavouring ingredients. Thus *claret cup* may be made of one quart of claret, one bottle of soda-water, half a pound of pounded ice, four tablespoonfuls of pounded sugar, a little grated nutmeg, a liqueur glass of Maraschino, and a sprig of green borage. *Champagne cup* may be made of one quart of champagne, two bottles of soda-water, one glass of brandy, one pound of pounded sugar, with borage or cucumber rind. *Cider cup* is similarly compounded.

Cup, DIVINATION BY, a mode of foretelling events, practised by the ancient Egyptians, and still surviving, though with but little credit, in some of the rural districts of England and Scotland. One of the eastern methods consisted in throwing in small pieces of gold or silver leaf into a cup of water, in which also were placed precious stones, with certain characters engraved upon them. The infernal powers were then invoked, and returned answer, either in an intelligible voice, or by signs on the surface of the water, or by a representation in the cup of the person inquired about. By the modern method, a person's fortune is foretold by the disposition of the sediment in her teacup after pouring out the last of the liquid.

Cupar, or CUPAR-FIFE, the county town of Fife, on the Eden, 10 miles W. by S. of St Andrews, 30 NNE. of Edinburgh, and 13 S. of Dundee. In the 12th century a castle of the Macduffs, Earls of Fife, crowned the 'School Hill,' whose northern slope was afterwards the show-place of mystery-plays and moralities such as the *Thrie Estaitis*

(1535) of Sir David Lyndsay (q.v.). Cupar has a handsome new Free Church (1877), the Duncan Institute (1870), and a public park (1871-72). Brewing, tanning, &c. are carried on; and there is a large corn-market. Lord Campbell was a native. The place has been a royal burgh since at least 1363, and it unites with St Andrews and five other towns in returning one member to parliament. Pop. (1851) 5605; (1881) 5010. See also COUPAR-ANGUS.

Cupellation. See ASSAYING.

Cupid (Lat. *cupido*, 'desire'), also AMOR, the Latin name for the Greek Eros, the god of love. Eros is not mentioned in Homer, but occurs first in Hesiod, whose conception of him is that of a cosmogonic force uniting, as it were, in harmony and love, the conflicting elements of primal chaos. Thus Plato, in his *Symposium*, speaks of him as the oldest of the gods. Quite different, however, from this venerable and somewhat impersonal deity is the Eros of the epigrammatic and erotic poets, the Cupid of Horace and Ovid. The genealogy of this meddlesome divinity is rather confused. He is variously represented as the son of Aphrodite (Venus) by Ares (Mars), Zeus (Jupiter), or Hermes (Mercury). He appears as a wanton boy, playful and mischievous, with bow, arrows, sometimes a torch, quiver, and wings. The eyes are often covered, so that he shoots blindly. His darts could pierce the fish at the bottom of the sea, the birds in the air, and even the gods in Olympus. The immensity of space was his home, but like his mother, he specially loved the flowery thickets of Cyprus. Later poets make a number of Erotes (Amores and Cupidines), with the same attributes as the prototype. We find also an Anteros ('return love'), whose function it is to punish those who do not return the love of others. Thespiae in Boeotia was the chief seat of the worship of Eros; here was held the Erotidia, a quinquennial festival. Eros or Cupid was a frequent subject for Greek and Roman works of art. The most celebrated statue was that by Praxiteles at Thespiae.

The beautiful fable of Cupid and Psyche, as given by Apuleius, is a literary version of one of the best-known stories in the world. Of course it is merely an ordinary household tale, with nothing but the names to connect it with the recognised Greek mythology. Here Cupid is merely the invisible bridegroom of scores of stories the world over, with the added name and attributes of the winged son of Aphrodite. See a study of the myth by Andrew Lang, in the introduction to his reprint (1887) of Adlington's translation (1566) of the story as told by Apuleius.

Cup-markings on rocks and CUP-MARKED STONES belong to a peculiar class of archaic sculpturings which have recently attracted much attention among archaeologists. Cup-markings on rocks are chiefly of two varieties—circular cavities or 'cups' pure and simple, and cups surrounded by circles. The circles round the cups are shallow indentations, varying in number up to five or six. Both cups and circles often show the marks of a pointed tool, as if they had been formed by picking, but frequently they appear as if weathered or abraded to a perfectly smooth surface. The cups vary in size from about one inch to three inches or more in diameter. Sometimes they are confluent at the edges, but more usually separate, and occasionally two or more are connected by a shallow groove or duct. They usually occur in groups, sometimes to the number of several hundreds. In such groups the majority are plain cups, intermingled with occasional cups and circles. The circles placed concentrically round the cups are occa-

sionally incomplete at one side, and a radial groove or duct passes from the central cup out through the circles. The circles are only approximately circular, sometimes oval, and occasionally even roughly quadrangular. These groups of cups, mingled with cups and circles, and occasionally with imperfect spirals and other rude and irregular sculpturings, are found on the stones of sepulchral structures of the stone and bronze ages, on rock-surfaces and earth-fast boulders, and on loose stones of small size in the neighbourhood of sites of early habitations or strongholds over nearly all Europe. They are still subjects of superstitious regard in Scandinavia, and while they are found in connection with the megalithic monuments of Europe and India, Mr Rivett Carnac has traced a resemblance to them in the conventional symbols of Siva in the modern temples. On the other hand Dr Veckenstedt found recent cup-markings (but without the characteristic circles) on the walls of churches in Prussia. Dr Rau has described a considerable number of examples from various parts of America, but few with circles. Many of the smaller cupped stones he attributes to the Indian custom of cracking hickory nuts, by laying them in such cavities and striking them with another stone. The larger-sized cups and basin-shaped cavities in earth-fast boulders and rocks he classes as mortars. But the more elaborate sculpturings on rock-surfaces present the central cup, the surrounding circles and the radial groove of the European and Indian examples, and the inference is that they belong to the religious or ceremonial symbolism of primeval man. The most remarkable examples of rock-surfaces sculptured with cups and circles in Scotland are those at Achnabreac in Argyllshire, described by Professor Sir J. Y. Simpson, and at High Banks in Kirkcudbrightshire, discovered in 1887 and 1888, and described by Mr George Hamilton in the *Proceedings of the Society of Antiquaries of Scotland*.

See *Archaic Sculpturings of Cups and Circles, &c.*, by Sir J. Y. Simpson (Edinburgh, 1867); *Incised Markings on Stone, &c.*, from drawings made for the Duke of Northumberland (Lond. 1869); *Skandinavien's Hällristningar* at A. E. Holmberg (Stockholm, 1848); and *Observations on Cup-shaped and other Lapidarian Sculptures in the Old World and in America*, by Charles Rau (Washington, 1881).

Cu'pola (Ital., from the root of *cup*), a spherical vault, or concave ceiling, on the top of a building; the internal part of a Dome (q.v.). The term is also sometimes used for a dome which is ogival (not hemispherical or semi-elliptical) in outline, or for a small dome. Cupolas are often wholly or partially of glass. There are cupola-furnaces; see IRON.

Cupping is one of the simplest and most popular methods of producing local depletion, by the application of partially exhausted *cupping-glasses* to the surface of the skin. By this means the blood is diverted from deeper structures to the surface of an affected part, whence it may be removed by scarifying the skin (wet cupping), or where it may be allowed to remain exuded in the subcutaneous tissues like a Bruise (q.v.), until it be removed by absorption (dry cupping).

Cupping has been a part of surgical practice from the earliest times, and instruments for performing it have been found in use among the least civilised nations. Of old, the cups were either small horns, open at both ends, from which the air was withdrawn by suction at the narrow extremity, or glasses of various shapes, with a small hole in the bottom of each. This hole was plugged with wax, the air exhausted by heat, and when the operator wished to remove them, he withdrew the plug, and allowed the air to enter. The modern cupping-glass is a beaker containing 3 to 6 fluid ounces,

with a finely-ground rim, which adheres closely to the surface of the skin.

The principal improvements have been in the methods of incising the skin. This used to be effected with a common lancet or narrow knife, with a short blade and convex edge, set in a long elastic handle, which the operator struck rapidly with his finger, so as to drive the blade 20 or 30 times into the skin. This was so tedious an operation, that a number of similar blades came to be used at once. These are contained in a box, which has slits pierced in it corresponding to the number of blades; the latter can be caused to emerge by setting free a spring, which causes them to revolve suddenly, and in doing so they protrude at the slits more or less, according to the regulation of the instrument by the operator. This apparatus is known as a 'scarificator.' A scarificator, glasses, a torch, some spirits of wine, and a lighted candle are placed ready at hand; the part is sponged with hot water, so as to cause an increased flow of blood into it; then dried with a warm towel; the torch, previously saturated with the spirits of wine and lighted, is held for an instant in one of the glasses. By this means the air in the glass is quickly expanded, and when the glass is then rapidly applied to the smooth damp surface of the skin, the rapid rarefaction of its contained air causes it to adhere tightly, and gives rise to determination of blood to the part to which it is applied. When the skin under the glass has become red and swollen, the cupper removes it, applies the scarificator, and as rapidly as possible again exhausts the air from the glass, which he re-applies. The blood will now flow into it; and when enough has been taken, the glass is removed, and some lint applied to the wounds. The number of glasses applied depends on the quantity of blood it is thought desirable to abstract; each one will probably withdraw from 3 to 5 ounces. This apparently simple proceeding requires considerable skill. The difficulties consist in regulating the depth of the cuts; for should they be either too deep or too shallow, the blood will not flow; in the one case, because the deeper vessels of the true skin are not opened; in the other, because the skin being completely cut through, the fat which lies beneath it is drawn up into the wounds, which it plugs, and stops the flow of blood. If, on the other hand, the glasses be completely exhausted of air, their rims press so firmly on the surface as to prevent the flow of blood to the part from surrounding areas of the skin, and as a result, very little blood flows from the wounds.

There are many modifications of the ordinary cupping apparatus, but all act on the same principle; and it need scarcely be added that extempore cups may be found in tumblers, finger-glasses, or any air-tight vessel with a smooth rim.

Dry Cupping is simply applying the cups as described, but not wounding the skin. A hard mass of extravasated blood is found occupying the skin at the site of this operation. The mass, at first cherry-red, becomes in a few days a dead black colour, then greenish, and finally yellow, following the usual course observed in the healing of a bruise.

Cupule (*Cupula*), in Botany, a shortened axis with a number of more or less cohering bracts, numerous and crowded in the acorn, or three in the beech-nut, which more or less completely inclose the ripening fruit. The husk of the hazel-nut may be regarded as an incipient cupule.

Cupuliferae (i.e. 'cupule-bearing'), an old order of dicotyledonous trees and shrubs, more naturally separated into (1) *Betulaceae* or *Corylaceae*, the beech and hazel family, including (a) the beech and alder,

(b) the hornbeam and hazel; and (2) the *Fagaceae* or *Cupuliferae* proper, including (a) the beeches, (b) the chestnuts and oaks. See the articles on these separate trees.

Cur, a name sometimes applied indiscriminately to small dogs of any kind not highly valued, and in this way often particularly appropriated to dogs of mongrel breed, but also used by naturalists as the common designation of many races, of which the Terriers (q.v.) may be considered as the type. See DOG.

Cura, CIUDAD DE, capital of Guzman Blanco state, in Venezuela, lies 60 miles SW. of Caracas, to the south of Lake Valencia. Pop. (1881) 11,644. —Area of the state, 33,770 sq. m.; pop. (1886) 515,418.

Curacao'o (also spelt *Curacao* and *Curassou*) is the most important of the Dutch West India Islands. It lies about 40 miles from the coast of Venezuela, is 36 miles long by 8 broad, and has a population (1886) of 25,203. The capital of Curacao is Willemstad, a very handsome town situated on the bay of St Anna, with 10,000 inhabitants. The soil of Curacao and its dependent islands is less productive than that of other tropical lands. The chief produce is salt, but careful cultivation produces sugar, tobacco, maize, figs, cocoa, coconuts, lemons, and oranges. The Curacao orange, *Citrus Aurantium curassaviensis*, is a peculiar variety. Willemstad is the headquarters of the colonial government, which has authority not merely over the neighbouring Windward Islands, Aruba, and Bonaire, but also St Eustache, Saba, and the Dutch part of St Martin. Altogether the Dutch West Indies have a population (1886) of 45,121. The trade is mainly with the United States. Curacao was discovered by Spain in 1527, taken by the Dutch in 1634, conquered by the English in 1807, and restored to Holland in 1815.

Curacao is a well-known and esteemed liqueur, usually made in Holland with the dried peel of the Curacao orange, the peel being macerated with water, and then distilled with spirit and water. The result is sweetened with sugar, and a little Jamaica rum is often added. A palatable imitation can be made from the fresh peel of bitter oranges and whisky.

Curari, URARI, WOORALI, or WOORARA, is a celebrated poison used by some tribes of South American Indians for poisoning their arrows. It is by means of this poison that the small arrows shot from the Blowpipe (q.v.) become so deadly. It is brought to Europe as a black, brittle extract, resinous in appearance, and encrusting the sides of little gourds containing it. The source of this deadly poison was for long unknown, owing to the natives jealously guarding the secret. The process of manufacture has now, however, been witnessed and described by several travellers, and in each case some species or other of *Strychnos* has been recognised as the source of the poison. There seem to be four distinct varieties of curari, each characteristic of a different tract of country, and probably varying in their physiological action; but for our purpose we may confine ourselves to that kind which is used in physiological experiments. Curari is one of those poisons which have little action when taken into the stomach, owing to the difficulty with which they are absorbed, but when introduced into a wound it acts with great promptness. The symptoms caused are loss of muscular power, feeble respiration, and death by suffocation. By means of artificial respiration it is possible to sustain life for a lengthened period, although the animal is apparently insensible to pain. In this

way it is employed in vivisection experiments as an anæsthetic.

At first it was supposed that curari contained strychnine, but as its action was so entirely different, this view was soon abandoned. Prolonged research has separated a special alkaloid, *Curarine*, which possesses the leading properties of the poison itself. *Curarine* differs from all other crystallisable alkaloids, save one, in containing no oxygen. It forms salts, and is said to be twenty times as strong as curari. In medicine curari is very little used. It has been proposed to employ it in lockjaw, hydrophobia, and as an antidote in poisoning by strychnia; but although it quiets the spasms, it has no direct curative effect, and it may cause an equally fatal paralysis.

Besides curari proper, there are two other arrow-poisons called Corroval and Vao. These, which are brought from New Granada, have an entirely different action on the body, as they primarily stop the beating of the heart, whereas with curari the heart continues to beat after breathing has ceased.

Curassow, or Hocco (*Crax*), a genus of large game-birds inhabiting the forests of Central and South America. Their most distinctive features concern the head. This is adorned with a crest of feathers, curled forwards, and capable of being raised and depressed; while the often brightly coloured cere is enlarged into a prominence at the root of the high beak. Eight species are found from Mexico to Paraguay, predominantly arboreal, living mostly on fruits, but in general habit like poultry. They are very unsuspicious of danger, especially careless at the love-making season, and are very readily tamed. The best-known species is *C. alector*—the Royal Pheasant of the Mexicans.

Crested Curassow.

It is a very sombre bird, about the size of a turkey. It is occasionally domesticated, and a stock imported into Holland at the end of last century seemed to become acclimatised. It was, however, lost amidst the troubles subsequent to the French Revolution. Though their love-making is keen, the birds are not very productive, and it is probable that the natives have discovered that this apparently very profitable bird will not breed readily under domestication. Closely allied, and of similar distribution and habit, are the fierce Guans and Penélopes (*Penelopina*), and the rare Mountain Curassow (*Oreophaps derbianus*). The Turkeys (q.v.) are also near relatives.

Curate, literally one who has the cure (Lat. *cura*, 'care') of souls, in which sense it is used in the Church of England Prayer-book, 'all bishops and curates'; as the cognate word *curé* is used in French to denote the incumbent of a parish. It is,

however, generally used now to denote the unbefitted parochial clergy in the Church of England, more exactly styled 'assistant curates.' Formerly, such curates were usually the deputies of non-resident incumbents, but now they are mostly helpers of resident pastors. A curate, in this sense, is a minister employed by the incumbent of a church (rector or vicar), either as assistant to him in the same church, or else in a chapel of ease within the parish belonging to the mother-church. He must be licensed and admitted by the bishop of the diocese, or by an ordinary having episcopal jurisdiction, who also usually appoints his salary. Any curate that has no fixed estate in his curacy, not being instituted and inducted, is liable to removal on six months' notice from the incumbent, and to summary withdrawal of his license by the bishop. In the latter case, an appeal to the archbishop of the province is open. But there are *perpetual* curates as well as temporary, who are appointed where tithes are inappropriate and no vicarage was ever endowed: these are incumbents, and not removable, and the impropiators are obliged to maintain them. Their title in new district parishes has been changed to that of vicar.

Curator to a Minor. See GUARDIAN.

Curb. See BRIDLE.—The disease in horses so called consists of strain of the straight ligament which runs down the back of the hock; is most common in animals with straight small hocks and that conformation known as *sickle hams*; whilst like other strains it occurs from sudden and violent exertion, often proceeding in the lighter breeds from leaping or galloping in heavy ground, and in the heavier, from the effort of keeping back a load whilst going down a steep incline. Swelling appears on the outer and back part of the joint, about 5 or 6 inches below the point of the hock, generally causing lameness, which is most apparent in trotting, and, in slight cases, usually decreases after the animal has been out for ten minutes. Fomentations must first be used to allay the irritation and inflammation, and a high-heeled shoe put in; when heat and tenderness disappear, cold applications will be advisable; after which the enlargement still continuing, a blister may be necessary; whilst, from the first, all work must be forbidden.

Curcas. See PHYSIC NUT.

Curculio. See WEEVIL.

Curcuma (Arab. *kurkum*), an Indian genus of Scitamineæ, the ginger and cardamom order. *C. longa* is widely cultivated in Southern Asia, its rhizomes (*radix curcumæ longæ* of pharmacists) being the source of Turmeric (q.v.). Young plants also yield a kind of arrowroot, but this is especially prepared from *C. leucorhiza*, with colourless rhizomes. *C. zedoaria* yields a tonic medicine (*radix zedoariæ officinalis* or *zedoary* of pharmacists), and is also used as food. *C. amadu* is the mango ginger of Bengal.

Curé, the name applied in France to a priest with a cure of souls, properly the priest of a regular parochial as opposed to a succursal church, but commonly applied to any pastor with spiritual functions.

Cures, an ancient town of the Sabines, 25 miles N.E. of Rome, whence the Romans, after the people of Cures united with them, came to be called *Quirites*. See ROME.

Cureton, WILLIAM, Syriac scholar, born at Westbury, Shropshire, in 1808, studied at Oxford, and was ordained in 1831. In 1837 he entered the British Museum as assistant-keeper of manuscripts, and here his labours brought to light a Syriac version of the Epistle of Ignatius (q.v.), remains

of a Syriac recension of the Gospels, and other MSS. of more or less value, which involved their editor in long controversies. In 1849 Cureton was appointed canon of Westminster and rector of St Margaret's. Among other honours, he received the degree of LL.D. from Oxford and of D.D. from Halle, and was a Fellow of the Royal Society and a foreign associate of the Institute of France. He died 17th June 1864.

Curfew (Fr. *couvre-feu*, 'cover fire'). To William the Conqueror is ascribed the introduction of the curfew-bell into England, the object of which was to warn the people to cover up their fires, and retire to rest. The time for ringing these bells was sunset in summer, and about eight o'clock in winter; and certain penalties were imposed upon those who did not attend to the signal. The practice of ringing the curfew-bell, however, appears to have prevailed throughout Europe long before the era of the Norman Conquest, its object being the prevention of fires, which, owing to houses being chiefly composed of wood, were then both frequent and destructive. The custom of ringing the curfew-bell at eight or nine o'clock is still continued in many parts of England, though its original significance is of course lost, and a list of the various places where the custom has been kept up will be found in *Notes and Queries* for 1883 and earlier years. The name has passed into literature as a current synonym for nightfall—it occurs in the opening line of Gray's *Elegy*. The curfew survives in some parts of New England. See BELL.

Curia. See ROME, also AULA REGIS.—The Papal Curia, or Curia Romana, the functionaries forming the court of the pope, including the congregations of cardinals, the secretariat of state, the functionaries through whom the holy see has relations with foreign powers. See POPE.

Curia Muria. See KURIA MURIA.

Curicó, a town of Chili, capital of a province of the same name, lies near the Río Lontué, 140 miles SSE. of Valparaiso. Pop. 10,110.

Curlew (*Numenius*), a genus of birds of the order Grallatores, and of the same family (Scolopacidae) with the snipe, sandpiper, avocet, stilt, &c. The bill is much longer than the head, slender, curved, and compressed; the face and head are feathered; the legs are slender, and part of the tibia is naked as well as the shank; the tail is short, and the folded wings extend about as far as the tail. The plumage is lark-like. The genus is cosmopolitan in its distribution. The Common Curlew (*N. arquatus*), the *Whaup* of the Scotch, frequents the seashores in winter, and elevated moors in summer. Its peculiarly weird and plaintive cry is familiar to every visitor of the

uplands. It feeds on worms, molluscs, and insects, and its long bill enables it to seek its food in marshy or boggy ground. A slight nest of leaves or other dry materials is built in some tuft of rushes or among long grass or heath, and usually contains four eggs. The curlew is good eating.—

Common Curlew (*Numenius arquatus*).

The Whimbrel (*N. phaeopus*) is a smaller species, much resembling the common curlew. Like the latter it is very widely distributed in the Old World, and frequently occurs on the shores of Britain, though apparently breeding only in the most northerly moors. North America has several species of curlew, some of which extend their summer migrations to very northerly regions.

Curling, a sport on the ice common in Scotland, where it is played by all classes of people in winter. Frozen-over lakes and rivers answer for the purpose, but under the auspices of curling clubs, artificial shallow ponds are maintained for the sake of this popular national sport; and the *bonspiels*, or set matches, are contested with great spirit. The sport is regulated by a body of rules issued by a central association called the Royal Caledonian Curling Club, which has grand matches in which hundreds are engaged once, if possible, every winter, and which awards medals to provinces and parishes for competition. The remarkable and pleasing peculiarity of curling is, that it produces for the time a thorough mingling of ranks—peers, peasants, clergymen, farmers, country gentlemen, and tradesmen, all meeting familiarly and hilariously for the

Curling-stone.

The Rink.

occasion. Latterly, curling has migrated to England, Canada, and other countries where Scotchmen can find ice of sufficient strength and keenness, and in Southport Glaciarium (1878) the game is played in summer on artificial ice. Curling is played with flattish round stones, about 9 inches in diameter, prepared by curling-stone

manufacturers, each stone weighing from 30 to 50 lb. Each of the players has a pair. The stones are provided with handles, to enable the player to hurl them on the ice with the proper degree of force. As at bowls, the stones are hurled to an assigned point or mark. The game is as follows: Sides are made up, usually consisting of four

against four, with a director styled *skip* for each; after which a certain length of ice is chosen on which to play. This is called the *rink*. Certain marks are then made at each end of the rink, consisting of several concentric rings, called *brougs*, and a centre, called the *tee*. The game is decided by time, or by one party first attaining a certain number of shots, such as 21 or 31; and the keenness displayed by rival sides in competing for victory is perhaps without a parallel in any other pastime whatever. One on each side plays alternately. The chief object of the player is to hurl his stone along the ice towards the tee, with proper strength and precision; and on the skill displayed by the players in placing their own stones in favourable positions or in driving rival stones out of favourable positions, depends nearly all the interest of the game. At a certain distance from each of the tees, a line—the *hog-score*—is drawn across the ice; and any stone not driven beyond this mark counts nothing, and is laid aside. In country places, a dinner composed of 'beef and greens,' the well-known curler's fare, generally concludes the day's diversion, which, taking place when outdoor labour is suspended, is felt to be no encroachment on rural occupations.

For laws of curling, and general remarks on the game, see *The Channel-stone* (four series, 1883-84), the last series of which contains an ample bibliography; *Descriptive and Historical Sketch of Curling* (1828), reprinted as *The Kilmarnock Treatise* (1883); *Curling, Ye Glorious Pastime* (1882), a reprint of the *Account of the Game of Curling* (1811); *Curling*, by Dr James Taylor (1884). There are, besides, the *Annals of the Royal Caledonian Curling Club*, 1839-88. This club in its jubilee year (1888) undertook the preparation of a volume, at once a history and a handbook of the game.

CURLL, EDMUND (1675-1747), a notorious London bookseller of the first half of the 18th century. His connection with *Court Poems* (1716) led to his first quarrel with Pope, who afterwards made the bookseller figure in the *Dunciad*. He earned an unenviable reputation for the publication of indecent literature, which afterwards received the brand of Curlicism. He was twice (1716 and 1721) at the bar of the House of Lords for publishing matter regarding its members; was tried and convicted for publishing obscene books (1725), fined (1728) for the issue of *Nun in Her Smock* and *De Usu Flagrorum*, and spent an hour in the pillory for his *Memoirs of John Ker of Kersland*. His announcement of *Mr Pope's Literary Correspondence* (1735) led to the seizure of the stock, and furnished Pope (who has been proved to have instigated its publication) with a sufficient excuse for the issue of an authentic edition (1737-41). Curll did not deal solely in garbage, as is shown in a list of his containing 167 standard works, including Swift's *Meditation on a Broomstick* (1710), Dr South's works, &c. His *Curliad* (1720) is styled a 'hypercritic upon the Dunciad Variorum.' It was of Curll's biographies that Arbuthnot wittily said they had added a new terror to death.

Currach. See CORACLE.

Curragh, a large undulating down in the centre of County Kildare in Ireland, 2 miles E. of Kildare town. It is the property of the crown, and in it is a large camp of exercise, established in 1855, with accommodation for 12,000 troops (see CAMP). The Curragh of Kildare is even better known as a famous racecourse.

Curran, JOHN PHILPOT, Irish orator, was born at Newmarket in County Cork, son of the seneschal of the Manor Court there, July 24, 1750. At Trinity College, Dublin, he was as idle and reckless as he had been at school, but spite of his dissipation he contrived to learn something of law, and the boisterous uproar of his life in Dublin

and London shaped him into an orator. After two years at the Middle Temple, London, he was called to the Irish bar in 1775. Here his conviviality, his wit, and his vehement eloquence, soon made him a prominent figure, and led to his being employed in many of the greatest causes of the time. In 1782 he became King's Counsel, and next year was returned to the Irish parliament for Kilbeggan. He became a strong supporter of Grattan, but his eloquence proved less effective on the floor of the House than before an Irish jury. His sarcastic retorts led him into several duels, of which, in the course of his career, he fought no less than five, all fortunately without serious harm. Although a staunch Protestant like so many great Irish patriots, Curran had a warm sympathy with his suffering Catholic countrymen, and was eloquent and constant in his unavailing appeals to the government to change a policy which was driving the Irish into rebellion. With his defence of Archibald Hamilton Rowan in August 1792 commenced the long series of defences in state-trials which have shed such a lustre on his name. The insurrection at length broke out in 1798, but was speedily suppressed, whereupon the prosecutions of its leaders at once began. Curran flung himself into their defence with a heroic energy that rose above the brow-beatings of the bench and insured him an immortality of affection in the hearts of his fellow-countrymen. The last of his defences was that of Napper Tandy in May 1800. Then came the Union, which Curran had always opposed as 'the annihilation of Ireland.' His own health was now shattered, and soon domestic troubles followed to darken his later years. His wife eloped with a clergyman, and his youngest daughter, Sarah, pined away and died in Sicily, a few months after the hapless fate of her bright young lover, Robert Emmett (1803). Her story is immortalised in Moore's well-known lines, 'She is far from the land where her young hero sleeps.' After the death of Pitt (1806) and the accession to power of the Whigs, Curran was appointed Master of the Rolls in Ireland, an office which he held till his retirement in 1814. He died in London, 14th October 1817. His remains were re-interred in Glasnevin Cemetery, Dublin, in 1834. Curran's little figure, ugly face, bright black eyes, and intense vivacity, formed a sufficiently unique personality; but his brilliant wit, his quickness in repartee, his mental acuteness, and the astonishing felicity of his ready language were altogether unparalleled, and made him easily the master of his company. He well deserved O'Connell's epitaph: 'There never was so honest an Irishman.' See *Lives* by his son, W. H. Curran (1819), A. Stephens (1817), and O'Regan (1817); also Ch. Phillips, *Curran and his Contemporaries* (1850). His *Speeches* were edited, with a *Life*, by Thomas Davis, in 1855.

Currant, a name originally belonging to a small kind of grape (see CURRANTS), and transferred, in consequence of the similar size of the fruit, to many species of Ribes (order Saxifragaceae, sub-order Grossulariaceae). The species known as *currants* are destitute of spines, and have the flowers in racemes: the spiny species are known by the name Gooseberry (q.v.). Among the fruit-shrubs most generally cultivated in our gardens is the Red Currant (*R. rubrum*), *Grosseille* of the French, a native of woods and thickets in the south of Europe, found also in some parts of Asia and of North America, perhaps rather a naturalised than a truly native plant in Britain. It has long been cultivated, although it does not appear that it had a place in the gardens of the ancient Greeks or Romans. The berries, besides being used for dessert, and to a much greater extent for pies, and for making jelly (eaten with mutton and hare), are used

also for making an agreeable and refreshing beverage, called in France *Eau de Groseilles* (made of the juice of the fruit, water and sugar, strained and iced), and a well-known fermented liquor called *Currant Wine* (q.v.).—The White Currant is a mere variety of the red, the result of cultivation, with fruit less acid, and more fit for

Red Currant.

dessert, generally also rather larger. There are many sub-varieties, and many intermediate shades of colour. Both the red and the white currants are either trained as standard bushes, or against walls, the latter treatment producing larger and finer fruit, and both are sometimes trained on a north wall, to retard their ripening till after the ordinary season. They grow readily, like the shrubs of this genus in general, from cuttings. Unlike the black currant, the red and the white grow in clustered bunches.—The Black Currant (*R. nigrum*), *Cassis* of the French, grows in moist woods, and on the banks of streams in Europe and the north of Asia. The fruit is much larger than the red currant, and cultivation has lately produced varieties remarkable for size.

There is a variety found in Russia with yellow berries. The jelly and preserve made from it are very useful for sore throats, as is also *black currant vinegar*, made in the same manner as raspberry vinegar. In Russia, the berries are gathered in large quantities in the woods, and dried in ovens, to be used in pies. They are tonic, and also slightly diuretic and sudorific. A liqueur, called *Liqueur de Cassis*, is prepared in France from the black currant, and it has been suggested to introduce this manufacture in the Hebrides and Shetland Islands. Those who are fond of the flavour of green tea in mixture with black, but to whom it is injurious, may effectually gratify their taste by dropping one or two leaves or a bud or two of black currant into the teapot during the process of infusion.—Many other species, some of them probably deserving of cultivation, are found in temperate and cold climates in almost all parts of the world. One with large beautiful red berries, occurs on the Himalaya at an elevation of 13,000 feet.—*R. oxyacanthoides*, a native of North America, is much like the common gooseberry in flavour, and the colour is red or green in different varieties.—*R. lacustre*, also a North American species, produces its fruit in bunches, a fruit like that of the black currant.—The fruit of *R. fragrans* is sweet, but the species is more remarkable for the production of a pleasant balsamic resin which exudes from the under side of the leaves in yellow drops and has the smell of black currants.—The Red-flowered Currant (*R. sanguineum*), now so common as an ornamental bush in shrubberies, and trained on walls, producing in April a profusion of deep-red flowers in large drooping racemes,

is a native of the north-west of America, and was introduced into Britain in 1826. Its bluish-black, mucilaginous, insipid berries are not, as is popularly believed, poisonous.—The Golden Currant (*R. aureum*), also a very ornamental shrub, from the same regions, has a tubular calyx and long golden-yellow flowers. Its fruit, which is either yellow or black, and of fine flavour, is not freely produced in Britain.—The name Native Currant, or Australian Currant, is given in Australia to the berries of different shrubs, particularly the white berries of *Leucopogon Richei* (order Epacridaceæ). Other fruits bearing the same name are produced by species of *Coprosma* (order Cinchonaceæ), but they are very inferior.

Currants, a small kind of raisin, are the dried red or blue berries of a small-fruited seedless variety of the common vine, which is cultivated in the East, and especially the Ionian Islands and in Greece. The name, originally *Raisins de Corinthe*, is derived from the city of Corinth, in the neighbourhood of which they were first cultivated. They are very small, round, with a thin skin, without seeds, and very sweet. Those brought from the island of Zante are most esteemed. The grafting, pruning, trimming, and irrigating of the vine-stocks, which of late have suffered from the phylloxera, involve much labour. As the grapes ripen, the bunches are dusted with sulphur, to keep off the dreaded *Oidium* (q.v.); rain at this period always injures and sometimes ruins the crop. The vintage is in August. The currants when ripe are spread out on drying-grounds in layers half an inch thick, and frequently turned. The currants, now loosened from the grape-stick, are tightly packed in barrels for exportation, and are an important Greek export. In a few districts of Greece, a very sweet wine is made from currants. Formerly there was heavy duty on currants imported into Britain, which fell from 44s. per cwt. before 1834 to 7s. in 1860, at which it has since stood. In 1886 there were 123,951 tons exported from Greece, and 119,565 in 1887.

Currant Wine is made of the juice of red or white currants, to which is added about one pint of water for every four pints of berries employed. About a pound and a half of sugar is afterwards added to each pint of the liquor, a little spirits being generally also added, before it is set aside to ferment. A larger quantity of sugar is sometimes employed, and no water, and a stronger and sweeter currant wine is thus produced. Fermentation requires several weeks, and the wine is not fit for use for at least some months afterwards. Black currant wine is made in the same way from black currants, but the fruit is put on the fire in as small a quantity of water as possible, and heated to the boiling-point before it is bruised.

Currency means originally the capacity of being current, or, as Johnson defines it, 'the power of passing from hand to hand.' It is applied in practice to the thing that is so current, and generally to whatever, by being current among any nation or class of persons, serves as the money with which they buy commodities or pay their debts. It is necessary to be content with a practical explanation, without venturing on a scientific definition of the term, because, among the many disputed points in political economy, there is none productive of more exciting controversy than the proper regulation of the currency; and the advocate of each theory is apt to define the term according to the view he takes of the functions of government regarding currency. Whether correctly or not, it is applied in practice to everything that is received for payment. It differs from the word money, in its popular acceptance, in as far as it includes various

substitutes for the metallic money of a country, especially bank-notes. The leading question among political economists regarding currency is, how far it should be restrained. The most effectual method of restraining it is by confining it to the precious metals. If it were law that none but a gold currency should be used in any country, and if, at the same time, there were no effort to tamper with this gold currency, and give it an artificial value, the currency of that country would always be adjusted to the general level of prices throughout the commercial world, and if it were redundant would be at once exported, and if deficient at once imported in exchange for commodities.

A country which does not produce gold must pay for its gold with commodities, and consequently it is a very expensive currency, and therefore, ever since man's ingenuity was turned to trade, methods have been devised for superseding gold or the other precious metals by something cheaper. Unless, however, law or custom intervenes to give it efficiency, this cheaper material will only be worth its own (so-called) intrinsic value. A five-pound Bank of England note is worth so little in its intrinsic value as a picture upon thin paper, that such a value can hardly be expressed. It derives its power as currency from the obligation it fixes on a great rich corporation to make good its professed amount to the holder. We thus pass from a purely bullion currency to the next step of restraint, which is generally called a mixed currency. Here some maintain that no note should be issued unless the banker or other person issuing it has in his possession as much bullion as will pay it. Others say it is sufficient that he is bound to pay its amount in bullion on demand without his actually possessing the bullion throughout the whole period of the currency of the note. A third party, again, are for a currency entirely free of a metallic basis; they hold that naturally paper money, passing from hand to hand, will represent transactions, and will therefore come in the end to be made good in some shape or other; and they further hold, that if some losses should thus occur, these will be more than compensated by the rapid increase of trade and enterprise, caused by a free trade in currency, as it is termed—that is to say, by every man issuing his own notes or promises to pay to whoever will take them. As a matter of fact, every nation beyond the first stage of civilisation has always regulated its currency, and Adam Smith carefully points out that this is no real infringement of natural liberty and free trade. Through a succession of practical measures, reached with considerable caution, the English have come to a mixed currency, resting on a compromise between the two classes of mixed currency above referred to. In the theory of the measures brought to completion under Sir Robert Peel in 1844, it is admitted that, to a certain extent, a currency can be based on transactions and the property of those concerned in them, but that a limit must be drawn, to prevent the power of creating such a currency from running to excess, by the issue of notes which cannot be immediately made good by those who issue them. Accordingly, the several banks in existence were allowed to continue their note circulation, but they were permitted to increase it only on the condition of having bullion in their coffers to pay the additional notes issued by them.

A currency which is not worth its nominal value in bullion is called a 'depreciated currency.' During the period of the restriction of cash payments (1797-1821), the notes of the Bank of England were at one time (1816) depreciated 16½ per cent. Before the resumption of cash payments, the notes of the Bank of England had sunk to be worth but 16s. in

the pound, as compared with gold. During the civil war in the United States, the paper dollar sank in 1864 to 38 cents; it did not reach par (100 cents) till 1879. A depreciated currency may be created by a government calling notes or any other form of money a legal standard, and issuing a greater quantity of it than the real transactions of the country and the property passing from hand to hand require; or it may be created by private persons acting under laws by which the right of issuing a currency is not duly limited. This faculty which a currency has of becoming depreciated without being repudiated, is the real source of danger in all proposals for an unfettered currency, or a free trade in the issue of money. If the bank-notes for which bullion cannot be immediately obtained were repudiated, there might be a natural check on over-issues; but it is their nature, on account of the difficulty of getting bullion for them, or the chance that it may never be got, that they pass at a discount or reduction of their value. Hence such a currency would be ever shifting; there would be no permanent standard, and the person incurring a debt before a depreciation which he pays afterwards would, in reality, be paying his creditor a dividend only. A 'token' currency, the material of which is avowedly overvalued, and which is issued in limited quantities for use in small payments, must be distinguished from a depreciated currency. In the silver currency of Britain, a pound is worth little more than four-fifths of a sovereign, even at the old valuation of silver, at about 60d. per oz. If a person due £100 could pay it in silver, he would get off with a dividend of from 16s. to 18s. in the pound; but by law, silver is not a legal tender for more than 40s. The copper currency is so far below its real value, that it has not been thought worth while to give it a permanent weight—the pence and halfpence now issued are little more than half the weight of those of former mintages; but they are only used as a medium for small sums, and the royal stamp is sufficient to establish a reliance on them. See BIMETALLISM, BULLION, MONEY.

Currents. OCEANIC, are treated in the articles on the oceans to which they belong—ATLANTIC, PACIFIC, &c. See also GULF STREAM, SEA, and the Map of the Atlantic in Vol. I.

Currie, JAMES, the earliest editor of Burns, was born at Kirkpatrick Fleming manse, in Dumfriesshire, 31st May 1756. He spent five years at Cabin Point, Virginia, in a mercantile situation (1771-76), then studied medicine at Edinburgh and Glasgow; and settling in Liverpool in 1780, soon obtained a good practice. His chief medical work was the able *Reports on the Effects of Water in Febrile Disease* (1797); but he is best remembered by his edition of Burns (1800; 7th ed. 1813), with a Life and criticism of the poet's writings, which he undertook solely for the benefit of Burns's family, and which was long the basis of all subsequent editions. Dr Currie died at Sidmouth, 31st August 1805. See the Life by his son (2 vols. 1831).

Currying. See LEATHER.

Curry Powder, or CURRY PASTE, is a compound of turmeric, coriander, pepper, ginger, and various spices; it is used to a large extent in India and elsewhere as a seasoning for a variety of dishes.

Curse of Scotland, a term popularly applied to the nine of diamonds in a pack of playing-cards. Perhaps the least worthless of the many explanations offered is that it involves a reference to the detestation entertained in Scotland towards John Dalrymple, first Earl of Stair, on account of his activity in promoting the Union, and especially for his share in the Massacre of Glencoe. His heraldic

bearings, 'or, on a saltire azure, nine lozenges of the field,' bore a fanciful resemblance to the nine of diamonds.

Cursing. See SWEARING.

Cursitor, an old name for clerks of the Court of Chancery who made out writs. The *Cursitor Baron* used to administer oaths to sheriffs, bailiffs, &c.

Curtain, in Fortification, is the portion of rampart connecting one Bastion (q.v.) with another.

Curtesy. See COURTESY.

Curtis, GEORGE WILLIAM, American author, born in Providence, Rhode Island, in 1824; in 1850 joined the staff of the *New York Tribune*, and was one of the editors of *Putnam's Monthly* from 1852 to 1869. He commenced the 'Editor's Easy Chair' papers in *Harper's Monthly* in 1853, and became principal leader-writer for *Harper's Weekly* on its establishment in 1857. A novel, *Trumps* (1862), and most of his books appeared first in these journals. Until 1884 he was one of the most prominent and influential members of the Republican party; he afterwards supported Cleveland.

Curtius, ERNST, a distinguished German classical archaeologist and historian, born September 2, 1814, at Lübeck. He studied philology at Bonn, Göttingen, and Berlin, visited Athens with Brandis in 1837, and next accompanied his teacher, Otfried Müller, in his travels through Greece. For some time he taught in two Berlin gymnasia, next became extraordinary professor at the university there, and (1844-49) tutor to the Crown Prince of Prussia. In 1856 he succeeded Hermann as professor at Göttingen, whence he was recalled in 1868 to become ordinary professor at Berlin. Since 1853 a member of the Royal Academy of Sciences, he became in 1871 one of its permanent secretaries. His earlier works were *Klassische Studien* (1840), *Anecdota Delphica* (1843), *Inscriptiones Attice Duodecim* (1843), and *Die Akropolis von Athen* (1844). The fruits of his repeated visits to Greece and Asia Minor—last in the spring of 1874, to make preparations for the intended excavations at Olympia at the instance of the German government—appear partly in the memoirs of the Göttingen Society of Sciences and of the Berlin Academy, and partly in his books, *Naxos* (1846), *Olympia* (1852), *Die Ionier* (1855), *Die Topographie Kleinasiens* (1872), and *Ephesos* (1874). His orations, delivered at Göttingen in the capacity of 'Professor Eloquentie,' were collected in 1864; those at Berlin, under the title, *Altertum und Gegenwart* (2 vols. 1875-82). Besides these and numerous papers in the special archaeological and philological journals, Curtius has published *Peloponnesos* (2 vols. 1851-52), a luminous description of that part of Greece, and *Griechische Geschichte* (Berlin, 3 vols. 1857-61; 5th ed. 1881, *et seq.*), a work of marvellous learning, unequalled for its insight into the artistic growth and development of the Greek race. It has been translated into English by A. W. Ward (1868-76). Besides these, Curtius has published with Kaupert, the *Atlas von Athen* (1878); earlier, with Adler and Hirschfeld, *Die Ausgrabungen zu Olympia* (3 vols. 1877-78).

Curtius, GEORG, a distinguished classical scholar, the brother of the preceding, was born at Lübeck, April 16, 1820, and studied at Bonn and Berlin. After teaching some time at Dresden and Berlin, he became in 1849 extraordinary, in 1851 ordinary, professor of Classical Philology at Prague, and settled as such at Kiel in 1854, at Leipzig in 1862. He died August 12, 1885. One of the soundest Greek scholars in Germany, Curtius was the first philologist of the generation that succeeded the giants Bopp and Benfey. His most important

works were *Griechische Schulgrammatik* (1852; 15th ed. 1882), translated into many languages (into English in Dr Smith's series in 1863); next the *Erläuterungen* to the foregoing (1863; 3d ed. 1875), translated into English by Abbott in 1870; *Grundzüge der Griechischen Etymologie* (1858; 5th ed., with the collaboration of A. Windisch, 1879), translated into English by A. S. Wilkins and E. B. England, 1875-76; and *Das Verbum der Griechischen Sprache* (1873-76; 2d ed. 1877-80), translated by Wilkins and England, 1880. Other works were *De Nominum Græcorum Formatione* (1842), *Die Sprachvergleichung in ihrem Verhältniss zur Klassischen Philologie* (1845), *Sprachvergleichende Beiträge zur Griechischen und Lateinischen Grammatik* (1846), *Philologie und Sprachwissenschaft* (1862), *Zur Chronologie der Indogermanischen Sprachforschung* (1867; 2d ed. 1873), and *Zur Kritik der neuesten Sprachforschung* (1885), his last work, in which he vigorously assails the theories of the 'new grammarians,' and to explain the word-changes in a language maintains the necessity of a third principle of varying or sporadic change, in addition to invariable phonetic law and the operation of analogy. In the famous *Studien zur Griech. und Lat. Grammatik* (10 vols. Leip. 1868-77) Curtius united his own papers with those of his pupils and others, including Brugmann, Fick, G. Meyer, and Windisch. The ninth volume contained Brugmann's famous paper on the 'nasalis sonans,' which first marked the revolt of the 'neogrammatici' against the master and traditional philology. Curtius founded in 1878, with L. Lange, O. Ribbeck, and H. Lipsius, the *Leipziger Studien zur Klassischen Philologie*.

Curtius, METTUS or METTIUS, a noble Roman youth who heroically sacrificed his life for the welfare of his country, 362 B.C. A yawning chasm had opened in the forum, and the soothsayers declared it could only be filled by throwing into it the most precious treasure of Rome; whereupon Curtius appeared on horseback in full armour, and exclaiming: 'Rome has no greater riches than courage and arms,' leaped into the abyss, which at once closed over him.

Curtius, RUFUS QUINTUS, a Roman historian, author of the work *De Rebus Gestis Alexandri Magni*, in ten books, of which the first two have been lost, and the text of the remainder has come down to us in an imperfect condition. Some critics have placed him in the reign of Augustus against the evidence of his style, which is moulded on that of Seneca, and would naturally suggest a writer contemporary with Claudius and Nero; others, as Niebuhr, under Severus; and others again much later. Curtius was poorly equipped as a historian, and his book has but little value as history; but its style, if mannered and declamatory, is elegant and pleasing. The *editio princeps* was published at Venice about 1471. Modern editions are those of Müttzell (1841), Zumpt (1849), and Vogel (1875-80).

Curule Chair (*sella curulis*), the chair of honour of the old Roman kings, and later of consuls, prætors, 'curule ædiles,' and some of the other higher magistrates of the republic having senatorial rank. It was a folding-stool originally of ivory, then of metal, with curved legs crossing.

Curvature. For Curvature of Strata, see ANTICLINE, GEOLOGY, MOUNTAINS; for Curvature of Spine, see SPINE.

Curve, a line described by a point moving so that the direction changes at every instant; and in mathematics the term curvature is restricted to lines that follow some law in their change of direction. Thus, the law of the circle is, that all points of it are equally distant from a fixed point, called the centre. The law of a plane curve is generally

expressed by an equation between the co-ordinates of any point in it referred to a fixed point; and thus the doctrine of curves becomes matter of algebra (see CO-ORDINATES). When the equation of a curve contains only powers of x and y , the curve is algebraic; when the equation contains other functions, logarithms, for instance, of x and y , the curve is called transcendental. The cycloid, e.g., is a transcendental curve.

There are also curves, like some spirals, that do not continue in one plane; these are called curves of double curvature, and require, in analysis, three co-ordinates and two equations. Curves are said to be of the first, second, third, &c. order, according as their equations involve the first, second, third powers of x or y . The circle, ellipse, parabola, and hyperbola are of the second order of curves. There is only one line of the first order—viz. the straight line, which is also reckoned among the curves.—The higher geometry investigates the amount of curvature of curves, their length, the surface they inclose, their tangents, normals, asymptotes, evolutes and involutes, &c.

The number of curves that might be drawn is of course infinite. A large number have received names, and are objects of great interest to the mathematician—in some cases, for their beauty, in others, for their geometrical properties. Among the most interesting are the following: (1) Circle; (2) ellipse; (3) hyperbola; (4) parabola; (5) cissoid of Diocles; (6) conchoid of Nicomedes; (7) lemniscata; (8) cycloid; (9) harmonic curve; (10) trochoid; (11) the witch; (12) cardioid; (13) curves of circular functions—e.g. curve of sines; (14) the logarithmic curve and other plane spirals, such as that of Archimedes, the lituus, the reciprocal or hyperbolic, and the involute (q.v.) of the circle; (15) the catenary; (16) the tractrix; (17) the tractrix; (18) the ovals of Cassini.

Curwen, JOHN, the apostle of the Tonic Solfa-system of teaching music, was the son of an Independent minister, and was born at Heckmond-wike, Yorkshire, 14th November 1816. He was trained for the ministry, and after having served as assistant in various charges, was settled as minister of the Independent chapel at Plaistow. In 1841 he began to advocate the sol-fa system; in 1843 his *Grammar of Vocal Music* appeared; and thenceforward he was indefatigable by lectures, books, and magazines in promoting musical knowledge and musical training. In 1864 he resigned his ministry and gave himself wholly to the cause. He died 6th May 1880. See SOL-FA SYSTEM; and *Memorials of John Curwen* (1882).

Curzola (ancient *Corcyra*), an island of the Adriatic, forming a part of Dalmatia; it is 30 miles long, by 5 broad. Pop. (1880) 12,388, 1995 of whom were in the town of Curzola, at the north-east extremity of the island.

Cush, in Genesis, the eldest son of Ham and father of Nimrod. The name is also used in Scripture for Ethiopia (q.v.), south of Egypt. But the Cush of Gen. ii. 13, watered by the river Gihon, could hardly have been in Africa, and many writers hold that the terms Cush and Cushites are also used of several Asiatic peoples in southern Arabia, on the Persian Gulf, in Babylonia (Akkadians), and near Ararat, who were all non-Aryan and non-Semitic.

Cushat. See PIGEON.

Cushing, CALEB, American statesman, born in Salisbury, Massachusetts, in 1800, was admitted to the bar in 1821, sat in the state legislature and senate, and was elected to congress in 1835-43. He arranged the first treaty between China and the United States in 1844; raised and commanded a regiment in the war with Mexico; and was United

States attorney-general in 1853-57, counsel for the United States at the Geneva Conference in 1872, and minister to Spain in 1874-77. He died in 1879.

Cushman, CHARLOTTE SAUNDERS, a distinguished American actress, born in Boston in 1816, appeared first in opera in 1834, and as Lady Macbeth in 1835. Miss Cushman played sometimes in high comedy, but her name is identified with tragic parts. In 1844 she accompanied Macready on a tour through the northern states, and afterwards appeared in London, where she was well received in a range of characters that included Lady Macbeth, Rosalind, Meg Merrilees, and Romeo—her sister Susan (1822-59) playing Juliet. Miss Cushman retired from the stage in 1875, and died in Boston, 18th February 1876.

Cusk. See TORSK.

Cusp (Lat. *cuspis*, 'a lance-point'). If we conceive a curve to be generated by a moving point, then a cusp is where the point suddenly stops and

Fig. 1.

Fig. 2.

returns for a time in the same general direction as that in which it was moving when it reached the cusp point. A later name is 'spinode.' When two branches (as BA, CA) meet a common tangent without extending further, the point of contact is a cusp. Fig. 1 is an example of the first species, and 2 of the second.

Cusparia. See ANGOSTURA BARK.

Cusps, curved projections or featherings in Gothic tracery, arches, panels, &c. They began in the Early English period, when they projected from the flat soffit of the arch; but they were soon comprised in the mouldings, and generally spring from the inner splay or cavetto. In Decorated and Perpendicular work the points were lengthened, and were frequently ornamented with flowers, heads, &c.

Cusp.

Cusset, a small town in the French department of Allier, 2 miles N.E. of Vichy, with two mineral springs. Pop. 5356.

Cusso, KUSSO, or CABOTZ (*Brayera anthelmintica*), a small Abyssinian tree of the order Rosaceae, sub-order Spiraeaceae, the dried flowers of which have been long infused in Abyssinia as an anthelmintic, and have been found so efficacious in the removal of tapeworm, that they were in 1874 introduced into European pharmacy as *Flores Kusso*.

Cust, ROBERT NEEDHAM, was born in 1821, at Cockayne-Hatley, Bedfordshire, studied at Eton, and entered the Indian civil service. He held various important administrative and judicial posts in North India, in 1864-65 was a member of the legislative council, and returned to England in 1866. He is a member of many learned societies at home and abroad, has contributed extensively to their Transactions, and has published works on the

modern languages of the East Indies (1878), of Africa (1882), and of Oceania, as well as *Linguistic and Oriental Essays and Sketches of Anglo-Indian Life*.

Custard, a composition of milk or cream, eggs, &c., sweetened with sugar, and flavoured according to taste. Custards are of various kinds, such as plain, baked, lemon, orange, almond, coffee custards, &c. For a plain custard, take four eggs and beat them well with two tablespoonfuls of flour and a little cold milk. Season this with sugar, ground cinnamon, grated lemon-peel, and pour on a pint of boiling milk, stirring all the time. It may be either baked or boiled. If more eggs are used, the flour may be omitted. Flavouring ingredients may be added according to taste.

Custard Apple, the name commonly given in the West Indies and other tropical countries to the fruits of certain species of *Anona* (order Anonaceæ, allied to Ranunculaceæ). Some of the fruits of this genus are among the most delicious produced in tropical countries, as the Cherimoya (*A. cherimolia*), and even the Common Custard Apple (*A. squamosa* or *reticulata*), which is a native of America, but is now very common throughout the East Indies. It is a large, greenish, or dark-brown, roundish fruit, sometimes from its size and appearance called Bullock's Heart in the West Indies; the tree is of considerable size. Some other American species and varieties are sometimes called custard apples, and two or three which are natives of Western Africa. *A. muricata*, the soursop, *A. (Asimina) triloba*, the pappaw-tree of the warmer parts of North America, and *A. palustris*, the dog or alligator apple of the West Indies, may also be mentioned. *A. laurifolia* grows in Florida and the West Indies; its large fruit is hardly eatable.

Custer, GEORGE ARMSTRONG, American soldier, born in Ohio in 1839, graduated at West Point in 1861, and served with distinction through the civil war, retiring with the rank of major-general. He afterwards held various cavalry commands in the west, and several times defeated the hostile Indians. On 15th May 1876, with a force of 1100 men, he attacked a body of Sioux, afterwards found to number some 9000, encamped on the Little Big Horn, in Montana, and he and his entire command were destroyed. See his *Life* by Whittaker (New York, 1878).

Custom, in English Law. This is either general or particular. For the principal doctrines relating to general customs, see COMMON LAW. In order to establish particular customs as law, they must be proved by verdict of a jury, except the custom of the city of London, which is proved by certificate by the lord mayor, aldermen, and recorder. A particular custom must, like a general custom, be established as in force for a time whereof the memory of man runneth not to the contrary. A custom must have been uninterrupted and peaceable, reasonable, and certain; compulsory—i.e. not in the option of every person whether he will use it or not—and consistent with other customs.

The customs and usages of England were adopted by the United States government at its foundation as far as applicable to the condition of the country, and have the effect of positive law. They cannot be set aside by implication, but only by statutes. Customs and usages are frequently invoked in the interpretation of positive law, particularly when a conservative interpretation is required. A marked instance of this is found in the interpretation of generic words used in the federal and state constitutions and laws, so as to deprive women citizens of the right to the elective franchise in a government founded upon equality of citizenship, and to

restrict their industrial sphere. See CUSTOMS DUTIES.

Customs Duties, the portion of the revenue derived from a tax on imports. In some countries, customs duties are imposed on certain exports also. The origin of the term is connected with the long conflict between the crown and parliament as to the right of taxation, although the practice it signifies is as old as the Roman empire, and is even to be traced among the ancient Greeks. To meet the claims made by the House of Commons to the exclusive right to vote all supplies, it used to be maintained that there were certain duties on exportation and on importation to which the crown had acquired a right by *custom* (although it is certain that customs duties existed in England prior to the Norman Conquest), and after the power of parliament over this branch of taxation had been fully established it retained its old name. This tax, which originally was a sort of premium of insurance for protection from robbery, after the excise came in force was always applicable distinctively to goods changing place. There were customs not only upon things leaving and things coming to the British dominions, but also upon commodities transferred from one part to another. In Scotland the duty on commodities imported into any town from a foreign country was called the great custom; and the duty charged by a burghal corporation on commodities coming within its walls from the country districts was called the small or petty customs. After 1707 the Scotch customs duties became the same as those of England. At present the term customs duties applies in the United Kingdom solely to the tax levied on commodities imported from abroad.

The tax on imports was of old a simple percentage, familiarly known to the readers of English history as 'tunnage and poundage,' from the method in which it was levied on the tun of wine, or the pound *ad valorem* of other merchandise. These were subsidies granted first to the crown, and then for the maintenance of the authority and dignity of the state. That is to say, they were forms of public revenue; and many complications arose by the additions and alterations of successive governments. Out of this confusion, no doubt, arose the belief that customs duties might be utilised for fostering domestic industries and discouraging foreign competition. When it came to be held as an established principle, with regard to any trade, that the customs should be adjusted in such a manner as either to aid or to impede it, the regulations regarding that trade alone would have complexity enough for a whole code of customs laws, the original object of which was mere revenue. The more complex the arrangements, the more open were they to the operations of the smuggler or defrauder, and, consequently, regulation had to be added to regulation, till the whole became a chaos. Frequently the duties were such as to act as a prohibition to importation, and they always added a heavy increase to the price. Sometimes there would be relaxations in favour of the produce of British colonies, and sometimes of some favoured country with which Britain had a treaty of reciprocity. Then, to encourage trade and manufactures, it was considered politic to allow goods to be imported for re-exportation abroad, or to be imported for the purpose of being worked up into a manufacture, and there would be a difference between the extent of encouragement granted to that manufacture if it were for home consumption or for exportation. The method in which such relaxation was accomplished was at first by charging the duty on the importation, and afterwards repaying it by what was called a 'drawback;' and this was subse-

quently accomplished in an easier method for the importer, by allowing him to 'bond' the goods in the government warehouses until the duty was paid, or the conditions which dispensed with it fulfilled. An ordinary importer was also allowed to 'bond' his goods, instead of being compelled, as in the old times, to pay duty on arrival of the vessel whether he had sold his cargo or not. See **BONDED WAREHOUSES**.

In the year 1825 the laws of the British customs were consolidated into some half-dozen statutes. It will give a conception of the confused and cumbersome condition into which the system had merged, to note that the number of acts repealed on the occasion of the consolidation was 443, and it was afterwards discovered that several had been omitted. There was still a long list of customs duties; but the free-trade legislation of 1846 cleared away a great mass of this burden on the commerce of the country, and there has been steady abbreviation of the list of duties or Tariff (q.v.). One by one, articles of food have been exempted; and nearly the whole customs revenue is now derived from spirits, wine, tobacco, tea, coffee, and dried fruits. The tendency has for some time been to concentrate the customs duties on a few articles, and yet they supply an enormous amount of revenue. The British revenue for the year ending 31st March 1889 is estimated at £89,287,000, and to this amount the customs contribute £19,800,000. Down to 1845 the tariff included some 1200 articles.

The defects which, according to the doctrines now prevalent in Great Britain, are to be avoided in a code of customs, are—1. The prohibition or discouragement of the importation of useful commodities; 2. Encouragement to the smuggler; and 3. Loss of revenue by raising the duty to the height which discourages importation. Under the first head, see **CORN LAWS**, and **FREE TRADE**. The second is connected with the view that on stimulants the duty cannot be too high, even though it should greatly impede their importation; but on the other hand, if the smuggling trade be encouraged, the stimulant is not only obtained without any contribution to the revenue, but the people become demoralised and trained to crime. Under the third head a memorable example was furnished by the old sugar-duties of France, which were so high that the native agriculturists could make sugar from beet-root cheaper than the duty-paid foreign sugar.

The collection and general management of British customs duties is under one great central department of the government in London. The office of receiver-general was in 1871 united with that of the comptroller-general, and there is a fourfold division into the paymaster's, examiner's, accountant's, and auditor's branches. The annual cost of collecting the customs dues and managing the necessary establishments is about £952,000, although the tariff contains now only twenty dutiable imports.

In the United States, the number of dutiable articles is large. Of the total imports the dutiable have nearly double the value of the free goods. Thus in 1887 the total imports had a value of \$692,320,000, of which \$234,220,000 were free of duty, and \$458,100,000 were dutiable goods. In that year the percentage paid on dutiable articles was 47·43. The increasing surplus derivable from this source has led to keen debate, and proposals for reduction of tariff. See also **DUTIES**, **TAXES**.

CUSTOM HOUSE (Fr. *douane*, Ger. *Zollamt*), the office at a seaport or frontier where the customs duties are paid, vessels entered and cleared, &c. In England the custom-house officer has the right of personal search only when he has good cause to suspect that contraband goods are concealed about the person. See **SMUGGLING**.

Custos Rotulorum (Lat., 'keeper of the *rotuli* or rolls') is the person appointed by the crown to keep the records of the county sessions. The office is an ancient one, and can only be held by a justice of peace. In fact it is usually held by the lord-lieutenant. In practice the rolls are kept by the clerk of the peace, an officer appointed by the *Custos Rotulorum*.

Custoza, a village 10 miles SW. of Verona, where the Italians have twice been utterly defeated by the Austrians. On 23rd—25th July 1848 Charles Albert was routed after severe fighting by Radetzky with a smaller force, and forced to retreat behind the Mincio; and on 24th June 1866, Victor Emmanuel with 130,000 men was defeated by the Archduke Albert with 75,000 men.

Cüstrin. See **KÜSTRIN**.

Cutch (*Kachchh*), a protected principality under the government of Bombay, stretches along the Gulf of Cutch and the Indian Ocean between Gujarat and Sind. Excluding the Rann of Cutch, it is 160 miles long from E. to W., and 30 to 70 broad from N. to S. The state, exclusive of the Rann, consists of 6500 sq. m., is the belt on the seashore, touching Sind, of which it may be regarded as a physical continuation, on the north-west, and being separated by a detached portion of the Rann from Gujarat on the south-east. While the southern edge of this belt is merely a sandy desert, the northern section, traversed lengthwise by two parallel ranges of hills, presents, amid much sterility, many fertile tracts, which yield cotton, rice, &c., and feed a large stock of horses, kine, buffaloes, and camels. The grand defect of the country is the scarcity of water. The mineral productions are coal, iron, and alum. The traces of volcanic action are numerous, and earthquakes also have recently occurred, as in 1819, 1844, 1845, 1864; that of 1819, besides shaking every fortified city to its foundations, and destroying many hundred lives, changed the level of part of the Rann. The population of the state, according to the census of 1881, was 512,084, being about 78 individuals to a square mile. The ruler is styled the Rao; and the feudatory chieftains under him are about 200. The capital is Bhuj.

The *Rann of Cutch*—subdivided into two parts, the smaller, of nearly 2000 sq. m., on the east, and the larger, of 7000 sq. m., on the north—is a desert, being mainly caked, hard ground during the dry season, and then in turn a sort of shallow lake formed by the heavy rains and pent-up tides of the south-west monsoon. It is supposed to have been originally a permanent inlet of the ocean, and to have had its level raised by some such convulsion of nature as that which marked the year 1819. The periodical disappearance of the waters leaves behind it one continuous crust of salt. This dreary waste has a few elevated spots on which a little vegetation grows. Herds of wild asses and clouds of flies are its only inhabitants. The sea is at present advancing into the little Rann year by year. For the substance called Cutch, see **CATECHU**.

Cuthbert, St., of **DURHAM**, was one of the three great saints of England in the middle ages, the other two being St Edmund of Edmundsbury, and St Thomas-a-Becket of Canterbury. St Cuthbert was born about 635. A legend, which was long generally believed, tells that he was born in Ireland, and drew his lineage from one of the petty kings of that country; but another tradition fixes his birth in what is now Berwickshire. When the light of record first falls upon him, he was a shepherd boy in the kingdom of Northumbria, which then stretched northwards to the Forth. In 651, while watching his flock by night on the heights of Lauderdale, he believed that he saw the heavens

open, and a company of angels descend upon the earth, and again ascend to heaven, carrying with them the soul of St Aidan, the pious Bishop of Lindisfarne, or Holy Island. The vision determined him to become a monk, and in the same year he entered the monastery of Old Melrose, of which St Boisil was then provost or prior, and St Eata abbot. When the latter removed to the newly-founded monastery of Ripon, Cuthbert accompanied him, and was appointed to the office of superintendent of the guests. In consequence of the dispute as to the keeping of Easter, which was then raging, Eata returned to Melrose, and Cuthbert, having accompanied him, was on the death of St Boisil in 661 elected prior of the monastery. While in this office, he distinguished himself by his assiduity in visiting the surrounding country, and especially the remoter mountain hamlets, sometimes on horseback, but oftener on foot, and labouring by his teaching and example to reclaim the people from the superstitious or pagan rites into which they had fallen. After a few years spent in this way, he left Melrose for the island monastery of Lindisfarne, of which he became prior, his old master, St Eata, being abbot. Longing for an austere life even than the monastic, he quitted Lindisfarne in 676, to become an anchorite, or solitary recluse, in a hut which he built with his own hands on House Island, one of the Farne group. Here, in 684, he was visited by Egfrid, king of Northumbria, Trumwine, ex-bishop of the Picts, and other great men of the north, who came at the request of the synod of Twyford to entreat that he would accept the bishopric of Hexham. He reluctantly complied with their wishes, but shortly after exchanged the see of Hexham for that of Lindisfarne. Still thirsting after solitude, at the end of two years he resigned his bishopric, and returned to his hut, where he died on the 20th of March 687. The anniversary of his death was a great festival in the early English Church, which commemorated also the 4th of September, as the anniversary of the day on which his body was translated to Durham. The influence which St Cuthbert exercised upon his age seems to have been due chiefly to his fervent piety and extraordinary asceticism. The gift of a persuasive tongue is ascribed to him, and he would seem to have had skill and prudence in the management of affairs, but nowhere is there any trace of his learning.

The fame of St Cuthbert had been great during his life; it became far greater after his death. Churches were dedicated to him throughout all the wide country between the Trent and Mersey on the south, and the Forth and Clyde on the north. It is stated that when his tomb was opened at the end of eleven years, his body was found incorrupt, and so, for more than 800 years, it was believed still to continue. It remained at Lindisfarne till 875, when the monks, bearing it on their shoulders, fled inland from the fury of the Danes. After many wanderings it found a resting-place at Chester-le-Street in 883. It was transferred to Ripon in 995, and in the same year it was removed to Durham. Here, inclosed in a costly shrine, and believed to work daily miracles, it remained till the Reformation. The grave was opened in 1826, when a coffin was found to inclose another, which there was reason to suppose had been made in 1104; and this again inclosed a third, which answered the description of one made in 698, when the saint was raised from his first grave. This innermost case contained, not, indeed, the incorruptible body of St Cuthbert, but his skeleton, still entire, wrapped in five robes of embroidered silk. Fragments of these, and of the episcopal vestments, together with a comb and other relics, found beside the bones, are to be seen in the cathedral library.

The asceticism which distinguished St Cuthbert in life, long lingered round his tomb. Until the Reformation, no woman was suffered to approach his shrine. His wrath, it was believed, was equally prompt to avenge every injury to the honour or possessions of his church. A cloth said to have been used by St Cuthbert in celebrating mass was fashioned into a standard, which was believed to insure victory to the army in whose ranks it was carried. Flodden was only one of many fields in which the defeat of the Scots was ascribed to the banner of St Cuthbert.

The Life of St Cuthbert was twice written by the Venerable Bede. Other ancient authorities are Symeon of Durham, and Reginald of Durham. See Raine's *St Cuthbert* (1828), Archbishop Eyre's *History of St Cuthbert* (1849; 3d ed. 1887), and Fryer's *Cuthbert of Lindisfarne* (1880).

The name *St Cuthbert's Beads* has been popularly given to single joints of the stems of fossil Crinoidea (q.v.), which being hollow could be strung on thread, and so made into a rosary.

Cuticle, a sheath formed outside a layer of cells, either by their secretory activity or by a modification of their external portions. In the strict sense, a cuticle is not in itself cellular, but consists of the products or of the modified portions of underlying cells. The thin envelope which may be readily stripped off a leech or earthworm when killed in spirit supplies a convenient example. A cuticle is usually formed outside relatively passive cells, but even ciliated Epithelium (q.v.) may have its cuticular outer layer through the pores of which the cilia emerge. By continuous modifications of the cells considerable thickness of cuticle may be developed—as e.g. the hard lining of the gizzard in many birds. By chemical modification of a well-developed cuticular formation very varied protective and offensive skin-structures often result. Thus the peculiar gelatinous, cellulose-containing tunic of Ascidians is for the most part a cuticle; the shells of molluscs are cuticular formations plus lime; the rasps of snails are formed from cuticle; the hard armour of Arthropods is a cuticle associated with the formation of Chitin (q.v.); the bristles, jaws, and firm sheaths of many worms are also cuticular, and so on. For the use of the term in special connections—e.g. the cuticle of the hair or of the teeth, see special articles. The term must not be confused with *cutis*, one of the names for the under skin or *dermis*; nor should it ever be used as equivalent to skin. See CELL, EPITHELIUM, SKIN.

Cutlass, a sword nearly 3 feet long, broad and nearly straight, mostly used by seamen of the royal navy. Those of the converted pattern of 1871 were pronounced utterly inefficient and unfit for service by a commission in 1887. See SWORD.

Cutlery, the general name given to such cutting instruments as knives, forks, scissors, razors, &c. The making of larger objects of this nature, such as axes, chisels, and saws, is rather the business of the tool-maker than of the cutler. Shells, flints, and other sharp-edged stones formed the rudest and most ancient cutting instruments, and the earliest traces of human existence in Britain and elsewhere are associated with stone 'celts' and other weapons and cutting implements. These were followed by bronze weapons and other articles, including reaping-hooks. In the museum of Bologna there are ancient Etruscan bronze knives carved in form somewhat like modern reaping-hooks, and in the great Naples collection of objects from Pompeii and Herculaneum, there are sickles, bill-hooks, knives, lancets, and spring-shears, some of which are made of iron or steel, as well as of bronze. These are of course ancient Roman.

Bronze, like steel, can be hardened, but by opposite means, since it is softened by sudden and hardened by slow cooling. The ancients appear to have been great experts in the tempering of bronze.

The Anglo-Saxons had knives somewhat resembling a razor-blade. They had forks also; but it would appear that these were employed for serving, not for use in feeding. The custom of using forks for eating with came from Italy, and was not known in England till the reign of James I. Before that, people fed themselves with their fingers, as is still the practice in the East. The Persians so much prefer this custom that they contemptuously call a fork a claw. Up to the end of the 15th century knives do not appear to have been much used at table, but as in those days everybody carried a knife in his girdle, it probably served to cut meat with as one of its applications. Spring-shears of the ancient Roman form were the only kind known up to Norman times, and probably even till the 15th or 16th century.

The London cutlers obtained a charter of incorporation in 1417 from Henry V.; but long before that knives were made at Sheffield, as the 'whittle' of that town, or village, as it would then be, is incidentally mentioned by Chaucer. Knives, sickles, shears, and scissors are named as being made in Sheffield, when the Hallamshire cutlers were incorporated in 1624. Cutlery was not then however an English specialty; and England still imported iron and steel goods largely from the Continent; and in England, Birmingham was in the 17th century regarded as the home of smiths and cutlers. The vast increase in the size of Sheffield since 1800 shows that it is chiefly during this century that its cutlery wares have expanded from being a mere inland into that of a world-wide commerce.

Table-knives.—Of these the best kinds are made by hand, and have the blade of steel, while the shoulder and tang, to which the haft is fitted, is of malleable iron. From the end of a thin bar of steel, which has been carefully brought to a proper heat, the blade is roughly forged, cut off, and welded to a piece of iron for the tang and shoulder. The latter, usually called the 'bolster,' is formed by crushing the hot iron between a pair of dies, and the tang drawn out by some strokes of the hammer. After reheating, the blade is again hammered and the maker's name stamped upon it. The next stage, that of hardening and tempering, is all-important in every kind of steel cutting instrument. Raising the blade to a dull red heat and then plunging it in cold water hardens it, but at the same time makes it brittle. The brittleness is removed and the steel made flexible by the process of tempering, which consists in again heating the blade till it acquires a bluish colour, and at this moment putting it back into the water. After tempering, the knife passes to the grinder, who smooths the bolster and works the blade a little on the grindstone. But the blade still requires to be made quite straight in the smithy, and again ground. The finishing processes of lapping, glazing, and polishing follow, in which different wheels are used along with emery and polishing-powder. The lap is covered with an alloy of tin and lead, and the glazing and polishing wheels with leather. Bone, ivory, horn, and other materials are employed for the hafts, but these are prepared by a different set of workmen.

Machinery is now used for the manufacture of blades of common table-knives, in which case blade, bolster, and tang are made of one piece of steel. A few strokes of a steam-hammer shape the blade, and without reheating the shoulder is formed, but it requires to be heated again for drawing out the tang. The blade is next reheated and hammered

thin, and then the whole of the metal portion of the knife is pressed into dies to give it the exact shape and size. Grinding and the finishing processes now follow.

Very cheap knives are made by simply 'flying' (i.e. pressing into dies) the blade and tang out of a cold sheet of steel at one operation, and dispensing with a shoulder.

Forks.—These are made from a bar of steel three-eighths of an inch square. The forger begins by forming the tang, shoulder, and shank. He then beats out flat a square piece left at the end for the prongs. In the next stage the whole is heated till it is soft, and pressed with some force between two halves of a die, which roughly form the prongs. The fork is afterwards filed, ground, brightened, and hafted. Forks of an inferior kind are cast.

Spring-knives.—Pocket-knives are of much more modern date than those used at the table. The earliest piece of cutlery made at Sheffield, or perhaps in England, was called a *thrytel* or *whittle*, and served for a weapon as well as for other purposes. At a later time the jack-knife appeared, which was made to shut into a groove in the handle, but had no spring. Some spring-knives are believed to have been made as far back as the beginning of the 17th century; but it was not till about 1820 that a spring-knife of the type now so much in use was invented by the first Lord Wharncliffe, or at least was named after him. The process of making the blade of a spring-knife does not differ much from that already described for a table-knife. Sometimes the springs are forged, but others are 'fied'—i.e. formed at a single blow out of a piece of steel. The inner scales of the haft are made of brass or iron, and sometimes of a more expensive metal; while a still greater variety of material, such as hard wood, horn of various kinds, ivory, bone, and tortoise-shell, is used for the outer scales.

Razors.—The use of the razor goes back to a very remote period. It is referred to in the book of Numbers, and was used by the ancient Egyptians as well as by the Greeks and Romans. The blade of a razor is forged from a piece of steel of the thickness of its back, and half an inch wide, the concave sides being formed on the rounded edge of the anvil. In the smithing process which follows, the workman hammers it to make it compact, and at the same time shapes it into proper form. It is next ground, hardened, and tempered; after which it is once more ground, and then lapped, glazed, and polished. The best qualities of razors are made of the finest cast steel, and are manipulated with great care in every stage of their manufacture. But there is always some uncertainty about the quality of a razor even when made with the utmost skill and care and from the best material. Perhaps this explains why high-priced razors are not in great demand, at least in Great Britain.

Scissors.—A blade is forged from a flat bar of steel, and this, including a bit for the shank and bow, is then cut off. Next a hole is punched for the bow to admit of its receiving the point of a small anvil upon which it is roughly shaped. After reheating, the bow is further shaped, the shank formed, and both filed. The joint is now squared, and the hole bored for the rivet or screw. Grinding and smoothing of the blade follow, and then the two are screwed together. If they work smoothly, they are ready for hardening and tempering, but the screw is first removed and the two halves wired together. Afterwards the scissors are ground and passed through the finishing processes already described.

In describing briefly the manufacture of the several articles of cutlery noticed above, only the

more important processes have been mentioned. The subdivision of labour is very fully carried out in the cutlery trade, so much so, that the man who forges the pen-blades does not forge the larger blades for the same knife. It is the same with those who grind the blades. Including those of a comparatively trivial nature, an ordinary three-bladed pocket-knife goes through more than a hundred processes.

The grinders in former years suffered so much from the fine particles of stone and metal which pervaded the atmosphere of the workshops that their average age did not exceed twenty-nine. This was especially the case with those engaged in dry-grinding, which, for example, was that used for forks. The evil has been lessened in recent years by the adoption in some establishments of wet-grinding, the water on the stone preventing the escape of particles of matter through the room. Another plan has been a good many years in use—namely, the application of a fan with a properly constructed flue, which withdraws by suction the grit and steel dust as it is produced.

A few of the leading manufacturers at Sheffield prepare hafting material such as ivory, wood, and horn on their own premises; but the manufacture of 'scales,' as these hafts are called, is to a large extent a separate trade. Ivory was long so popular a material for knife-handles that Sheffield has in some years consumed the tusks of 20,000 elephants; but owing to its increasing scarcity and price, various substitutes are now employed. In trading with savage people it is curious how they will sometimes unexpectedly reject a useful article on account of its colour. For example, the Fiji Islanders a few years ago, if not now, would on no account accept in barter a white-handled knife, but would readily take one with a black handle.

In cutlery France and Germany are now competing with England in many foreign markets; but the trade has again shown a tendency to increase in Sheffield. The manufacture is now also extensively carried on in the United States. In France the headquarters of cutlery are at Thiers, Langres, Nogent, Châtellerauld, and Paris, where the finest surgical instruments are made. Solingen is called 'the German Sheffield,' but Remscheid, Suhl, Schmalkalden, and many other towns produce knives and the like. Swedish razors are famous. See also SWORD.

Cuttack (*Kataka*, 'the fort'), the capital of a district in Orissa, Bengal, stands immediately below the bifurcation of the Mahanadi, thus occupying the apex of the delta of that river, a position advantageous both in military and commercial respects. The city, which is 220 miles SW. of Calcutta, is chiefly notable for its filigree-work in gold and silver. Pop. (1881) 42,650, of whom 7687 were Mohammedans.—The district is the central one of the Orissa division, and has an area of 3517 sq. m., and a pop. (1881) of 1,738,165.

Cutter is a name given to two kinds of small vessels. The cutters used by yachtsmen and revenue cruisers, and which are built with especial reference to speed, have a single mast, and a straight running bowsprit that can be run in on board occasionally. They are much like sloops in rig, but have larger sails. Such small vessels occasionally venture on long voyages. In 1857 the *Charter Oak*, a cutter of 23 tons, crossed the Atlantic from New York to Liverpool. In 1865 the *Alert*, a cutter of 56 tons yacht measurement, made the voyage from England to Sydney (Australia) in 108 days, including 5 days' detention at the Cape of Good Hope. From that time to this, long voyages with vessels of this class, especially across the Atlantic, have been matters of common

occurrence. See YACHT; for the other kind of

Gutter.

cutters, see BOAT.—In the United States, very long sleds, for coasting, are called *cutters*.

Cuttings are branches or portions of branches of trees or shrubs, employed to produce new plants, by burying the lower end in the earth so that new roots may arise from the nodes. Nothing is more easy than to propagate willows, fuchsias, pinks, geraniums, currants, gooseberries, &c. in this way; but many other plants, commonly propagated by cuttings, require greater attention on the part of the gardener, warmth, a uniform damp atmosphere, and shade. The term cutting is, however, usefully extended by most horticultural writers to any part of a plant which can be separated to become an individual similar to its parent; thus some plants may be propagated most readily from simple leaves or portions of leaves, others from a segment of stem bearing a single leaf with a bud at its base, others from offshoots at the base of the parent plant, some again from the younger shoots, and others from partially ripened wood, and so on. Hence there is room for considerable experience and skill, and detailed instructions should be sought by the amateur florist in works on horticulture (e.g. Johnson's *Dictionary of Gardening*). The most convenient general method, however, is to strike cuttings in well-drained shallow pots or boxes of silver sand overlying a little sandy peat or loam; shade and water being applied with discretion, and bottom heat only in special cases, which of course include the majority of stove plants. Hardy fruit-trees may be best propagated by cuttings taken after the fall of the leaf, and planted on the north side of a wall, but not so close as to be constantly in shade.

Cuttle-fish (*A.S. cudele*), strictly speaking, a member of the genus *Sepia*, more generally applied to any Cephalopod (q.v.). A brief account is here given of the structure, life-history, and habits of the common British species (*Sepia officinalis*, Linn.), with a tabular indication of its relationships.

The *Sepia* (fig. 1) measures from six to ten inches in length, and its colour varies from pale gray to dark brown or neutral tint. The body is oval, flattened from above downwards, and contained in a tough muscular sac (mantle), which expands along the whole of either margin into a narrow fin. The integument consists of a single layer of cells, lying upon connective tissue, in which are imbedded 'chromatophores,' or cells charged with variously coloured pigment-granules. By expansion of the cell the pigment is diffused, and by its contraction concentrated, hence the rapid flashes of changing

colour for which the cephalopoda as a whole are so remarkable.

The *head* is broad, and contains a cartilage of complex shape which protects the central nervous system, and forms a socket on either side for the large eye; this has a bright green lustre during life, the black pupil is shaped like the Greek letter ω , and there are two eyelids, the upper coloured, the lower white. The front of the head is occupied entirely by the bases of the arms and the mouth. The former are ten in number, eight of

1, *Sepia officinalis* from the dorsal aspect; 2, view of the Mouth, showing its Lip and the bases of the Arms and Tentacles; 3, the Shell seen from the ventral surface; 4, the same in lateral view; 5, the Animal with the Mantle divided in the middle line to expose the Branchial Cavity:

s, siphon; *t*, its valve; *c*, pit in the base of the siphon; *c'*, prominence on the mantle which fits into it; *m*, muscle passing backwards from the siphon to the mantle; *a*, termination of the intestine; *Br*, gill; *r*, renal opening; *g*, genital opening; *i. s.*, ink sac. At the base of the right gill a portion of the membrane has been removed to show the branchial heart.

them being alike, oblong in transverse section and tapering off to slender extremities; they have the surface which is turned towards the mouth covered with suckers in four longitudinal rows. The suckers consist of a muscular periphery, strengthened by a horny ring; a fleshy pad acts like a piston in the base of this latter. Each sucker is mounted on a short flexible stalk. The two remaining arms, known as 'tentacles,' occupy the interspaces between the ventral arms and those next to them. They are twice as long as the others, and have a cylindrical stem, slightly expanded at the extremity into a club furnished with larger and smaller suckers. They can be withdrawn into pockets situated beneath the eyes, and are carried in this position when not in use. The mouth (fig. 2), situated in the centre of the roots of the arms, is surrounded by a lip with seven prominent angles, which bear small suckers in some species, and have been compared to rudimentary arms. Projecting from it may be seen the two black horny mandibles, shaped like those of a parrot, but with the lower overlapping the upper.

On the lower aspect of the animal, between the muscular sac and the body proper which contains the viscera, is a hollow space, the 'branchial' or

'mantle-cavity.' When this is opened by a longitudinal incision it is seen to contain the following structures (fig. 5). Anteriorly is the base of the 'siphon,' or 'funnel,' *s*, a conical tube containing a valve, *t*, through which water can be forcibly expelled by the contraction of the mantle. At its posterior margin on either side is an almond-shaped depression, lined with cartilage, *c*, into which fits a prominence on the inner surface of the mantle, *c'*, an arrangement which largely contributes to the solidarity of the body as a whole. Lying along the middle line is the terminal portion of the intestine, *a*, furnished with two small flap-like appendages of uncertain function, and on either side, a little farther back, is a small papilla, *r*, upon which the kidney opens, and on the left side only, the genital orifice, *g*. Two large gills, *Br*, are situated in the lateral recesses of the mantle-cavity, each consisting of an arterial stem running up the attached side, and a venous stem passing down the other aspect, the bulk of the organ being made up of a series of folds passing transversely from one to the other, and richly supplied with vessels containing the blood to be aerated. Respiration is carried on by rhythmic contractions of the mantle, in consequence of which water enters at either side, passes over the gills, and is expelled by the siphon; this takes place about seventy times in a minute.

On the dorsal side of the animal, immediately beneath the integument, is a closed sac which contains the internal shell (cuttle-bone, sepiostere, figs. 3, 4). Speaking generally, this may be said to be of an elongated spoon or boat shape; it consists of a horny lamina, which gives it its characteristic outline, extending also into the small cone at the back, which in many species is much larger than in the one now under consideration, and has been compared with the guard of the Belemnite (q.v.). On the dorsal surface is a granular calcareous deposit; while the concave ventral aspect of the spoon is occupied by a series of layers of calcareous matter, which are deposited in succession and do not entirely cover each other, so that the hinder portion of this surface presents a striated appearance due to their parallel margins. This part of the shell is porous and extremely light, the interstices being filled with air. These shells are imported into Liverpool in some quantity, and ground into fine powder to form a dentifrice.

The Digestive Organs.—Within the beak above alluded to is a solid muscular mass (buccal cone), part of which is devoted to its movements. Through its centre passes the gullet, the lower wall of which bears a most remarkable organ, the tooth-strap or 'radula'; this consists of seven longitudinal rows of horny teeth, which are secreted by certain special cells of the epithelium, and whose apices are directed backwards. They can be moved to and fro by appropriate muscles. Behind the buccal cone the oesophagus bears the salivary glands, and still farther back it opens into a round saccular stomach with muscular walls. A large bilobed gland, commonly called 'liver,' but having the functions of a pancreas, is situated on the oesophagus. Lying parallel to the terminal portion of the intestine is the 'ink-bag,' *i. s.*, a hollow gland opening near the anus, and furnishing a deep-brown fluid, which is ejected by the animal when alarmed in order to conceal its retreat. When genuine, the pigment known as 'sepia' is prepared from it.

The Circulatory Organs.—The heart is situated posteriorly, and consists of a pear-shaped sac which receives on either side a vein from the gills, dilated just before its termination into a muscular con-

tractile antechamber or auricle. It gives off an artery anteriorly to supply the head and arms, and another posteriorly to the abdominal organs. The

blood, after being distributed throughout the body, is collected in veins which traverse the walls of the kidneys and pericardium, and eventually pass to the gills, at the base of which a muscular dilatation (branchial heart) is situated, serving to effect the circulation of the blood through the gills.

The *Nervous System* consists of the three pairs of ganglia common to the Mollusca concentrated round the œsophagus. One pair (pedal) supplies the arms and siphon; a second (pleuro-visceral) the gills, viscera, and mantle; a third (cerebral) the head and eyes. In the mantle on either side is a large nervous mass (ganglion stellatum) situated on the pleural nerve, and supplying the mantle. In addition to these parts, and connected with them, there is a system of so-called 'enteric' nerves, springing from the buccal ganglia, which lie on the œsophagus just in front of the cerebral ganglia.

Of the *Organs of Sense* the eyes are the most conspicuous. They occupy depressions in the head cartilage, the hinder part of which is occupied by the optic ganglia, ocular muscles, and a white glandular substance of unknown function. The retina consists of an inner layer of rods with swollen bases, and an outer layer of nucleated cells with a limiting membrane between them. The retinal chamber is closed in front by a spheroidal lens, made up of an inner and outer portion, which are secreted separately by an epithelial structure occupying a groove round its equator. In front of the lens is the iris, supported by a cartilage and containing a sphincter muscle; the outer surface of the whole organ is formed by the transparent cornea, which, though continuous in the Sepia, is perforated in the members of a large group of Cephalopoda (Egopsida).

The *ears* are a pair of small closed vesicles, imbedded in the head-cartilage, and supplied by nerves which, though apparently springing from the pedal ganglia, really have their origin in the cerebral. A ciliated pit, usually considered to be *olfactory* in function, lies behind each eye.

Generative Organs.—The sexes are separate. The testis and ovary are both single and situated in the hinder part of the body; the latter lies in the visceral sac or pericardium above described, the former in an almost closed diverticulum of it. The eggs have a tough capsule, with a projection at one end and a kind of handle at the other by which they are attached in bunches to a twig of seaweed or other similar substance. As in the hen's egg, the proportion of nutritive to formative yolk is very large, and the embryo, as it develops, comes to stand head downwards on the former.

Habits.—The animals are found in littoral regions or in moderately deep water; ordinarily they rest horizontally on or near the bottom, the fins gently undulating, the tentacles retracted, and the arms depressed (see cut at CEPHALOPODA). Progression may take place by means of the fins with considerable rapidity in either direction, the funnel being turned so that the stream of water issuing from it assists in propulsion; rapid darts backwards when the animal is alarmed are brought about either by the sudden ejection of water through the siphon, or by spreading out and reuniting the arms. When feeding, the Sepia remains motionless till its prey is within striking distance; then the dorsal arms are raised, the others open out sideways, the tentacles are shot forth with the rapidity of lightning, and the victim seized between their terminal clubs (see cut at CEPHALOPODA).

Distribution.—Fifty-eight recent species of Sepia have been described, of which some forty or fifty may be regarded as valid. By far the greatest number belong to the Indo-Malayan region, whilst, with one doubtful exception, none occur on the

shores of the New World. About a dozen fossil forms have been recorded from Tertiary deposits. For large and fabulous Cephalopods, see OCTOPUS, SEA-SERPENT.

Cutty Stool. See STOOL OF REPENTANCE.

Cutworm, a term used loosely of worms or grubs destructive to cabbage, beans, &c.

Cuvier, the chief of modern comparative anatomists, the first to unite the paleontology of extinct forms with the anatomy of the extant, important also as an educationist. Leopold Christian Frédéric Dagobert Cuvier, better known by his adopted literary title Georges Cuvier, was born on the 24th August 1769, in the town of Montbéliard, at that time belonging to Würtemberg. His ancestors were Protestant refugees from the Jura. He was destined by his parents for the church, but early exhibited a predisposition for natural history. In his education at Stuttgart, he came under the happy influence of the botanist Kerner and the zoologist Kiemeyer. At the age of eighteen he became tutor in a family living near Caen, in Normandy. There the abundant fossil Terebratulæ of the shore, the cuttle-fish and other molluscs landed by the waves, excited his eager interest, and became subjects of close study. There too he was introduced to Geoffroy St-Hilaire and other Parisian savants. Geoffroy at once recognised his abilities, and invited him to Paris. Cuvier accepted the invitation, became first assistant, and then professor of Comparative Anatomy in the Jardin des Plantes. Elected a member of the French Institute in 1795, he became in 1803 permanent secretary of the Academy of Sciences. In 1808 he undertook the reorganisation of public instruction, and shortly before the fall of Napoleon was admitted into the Council of State. After the Restoration he was made Chancellor of the University of Paris. After a visit to England in 1818, where he was received with great honour, he was, in 1819, admitted into the cabinet by Louis XVIII., and in 1826 was made grand-officer of the Legion of Honour. His decided opposition to the royal measures for restricting the freedom of the press lost him the favour of Charles X. Under Louis-Philippe he was made a peer of France (Baron Cuvier) in 1831, and in the following year he was nominated Minister of the Interior. Then his career was terminated suddenly from an attack of paralysis of which he died, May 13, 1832.

Cuvier's life was characterised by extraordinary activity. In his plans for the extension and improvement of national education, in his efforts for the welfare of the French Protestant Church, and in his scientific work, he was alike zealous and indefatigable. On every hand he gave evidence of gigantic intellect, and of honest, resolute character. He was conspicuous for an unsurpassed grasp of concrete facts, rather than for originality of suggestion or power of generalisation, and remained a vigorous and formidable opponent of the Theory of Descent.

In several departments of zoology, Cuvier's indefatigable industry and giant intelligence achieved great progress. (1) By marvellous energy in collecting, examining, and dissecting, he vastly increased the circle of accurately known forms, both living and extinct. (2) This was done, however, in a way which combined depth of insight with increasing breadth of view. He penetrated below external form to the internal structure, and not content with empirical dissection, rationalised his results in the first systematic comparative anatomy. His profound anatomical studies led him further to appreciate more clearly than heretofore the unity of the organism and the mutual dependence of its parts. In clearly defining the principle of the

correlation of organs, he recognised, to quote his memorable words, that 'the organism forms a connected unity, in which the single parts cannot change without bringing about modifications in the other parts.' (3) In his hands classification became more natural, being more thoroughly based on real similarities of structure, and less on superficial resemblances. He recognised the existence of four great types—Vertebrate, Mollusc, Articulate, and Radiate, a classification independently confirmed by the embryological researches of Von Baer. Although his four types are now known to give a false simplicity to nature, the establishing of structural classification, followed out in his subdivisions, introduced a new order in the animal kingdom. (4) Before his work, fossil forms had been very scantily known, and still less understood. His researches, however, especially among vertebrate remains, not only revealed an undreamt-of wealth of entombed forms, but disclosed to some extent the relation between the living and the dead. For the first time paleontology was linked to comparative anatomy, and the new contact brought fresh light. Yet it must be remembered that to him the Linnean dogma of the constancy of species seemed unassailable. Clear as he was in regard to the existence of fundamental and recurrent types, he was as determinedly opposed to the suggestion of Buffon, Lamarck, and others, that animals were connected by common descent.

Among Cuvier's more important works are the following: *Leçons d'Anatomie Comparée* (1801-5); *L'Anatomie des Mollusques* (1816); *Recherches sur les Ossements Fossils des Quadrupèdes* (1821-24); *Discours sur les Révolutions de la Surface du Globe* (introduction to the last); *Histoire naturelle des Poissons* (1828-49), written in concert with Valenciennes. Better known perhaps than any of these is the work which has passed through so many editors' hands—*Le Règne Animal distribué d'après son Organisation* (1817), more familiar in the enlarged and elaborated form which it received under the editorship of Cuvier's school. Important too for the history of zoology are numerous eulogies and historic reports delivered on various occasions throughout Cuvier's life.

See Mrs R. Lee's *Memoirs of Baron Cuvier* (Lond. 1833); Pasquier's *Eloge de Cuvier* (Paris, 1833); Carus's *Geschichte der Zoologie* (Munich, 1872); Haeckel's *History of Creation* (Lond. 1876).

Cuxhaven, a pleasant little German watering-place, on the southern bank of the Elbe, at its mouth in the German Ocean, 72 miles NW. of Hamburg by rail. The port whence the Hamburg steamers ply when in winter the Elbe is frozen over, Cuxhaven has an old castle and a safe harbour. Pop. (1885) 4490—in summer doubled by visitors.

Cuyabá, the capital of the Brazilian province of Matto Grosso, occupies pretty nearly the centre of South America. It stands on the left bank of the Cuyabá River, 980 miles NW. of Rio de Janeiro. Founded by gold-diggers in 1719, and wrecked by an earthquake in 1746, it is now a well-built place, with a cathedral and 8000 inhabitants. It can be reached by the rivers Paraná and Paraguay, a voyage of 2500 miles from Buenos Ayres.

Cuyp, or KUYF, JACOB GERITSE, commonly called the Old Cuyp, was born at Dordrecht in 1575. Jacob Cuyp's representation of cows and sheep, battles and encampments, are clever, but his fame rests principally upon his excellent portraits. His colouring is warm and transparent; his manner, free, and spirited. Cuyp was one of the four founders of the Guild of St Luke at Dordrecht, and died after 1649.—ALBERT CUYF, Jacob's son, was also born at Dordrecht, in 1605.

He excelled in the painting of cattle grazing or reposing, moonlights, wintry landscapes, still waters with ships, horse-markets, hunts, camps, and cavalry-fights; and in rendering effects of warm golden sunlight he is without a rival. During his lifetime and long after, Albert's pictures, although in many respects equal to those of Claude, were held in little estimation. Opinion, however, has now changed regarding them, and a fine example of his art has realised over £5000. England is particularly rich in his works, the National Gallery possessing eight of his subjects. He died at Dordrecht, 1691.—BENJAMIN CUYF, a nephew of Albert, was born at Dordrecht in 1608, and became a member of the guild there in 1631. He painted biblical pieces in Rembrandt's style, and familiar scenes of country life. His best works are in the manner of Teniers. His seashores have less repute.

Cuzco, a city of Peru, stands 11,440 feet above sea-level, in a valley of the Andes, 345 miles ESE. of Lima. It was the ancient capital of the Incas (in whose language, says Garcilaso, Cuzco signifies 'navel'), and at the time of its conquest by Pizarro (1533) had 200,000 inhabitants. Now it has only some 18,000, but it is one of the finest cities in the republic, with a cathedral (1572-1654), a so-called university (1598), and some remnants of Cyclopean architecture.—Cuzco gives name to a department, with 238,445 inhabitants. See PERU.

Cyanite, Kyanite (Gr. *kyanos*, 'blue'), DISTHENE, or SAPPHIRE, a mineral composed of alumina and silica. It often occurs crystallised, and generally in broad prisms. It is sometimes colourless, red, yellow, &c., but more frequently of a fine sky-blue, slightly tinged with violet; it is transparent, and sometimes beautifully opalescent.

Cyanogen, CN or Cy, although intrinsically of little importance, is one of the most interesting compounds of carbon. It was the first known compound body which was proved to be able to unite with elements in the same way as these substances unite with each other. Thus hydrogen, H, unites with chlorine, Cl, to form hydrochloric acid, and sodium, Na, unites with chlorine to form chloride of sodium, NaCl. Like these elements, H, Cl, or Na, each a single substance, the group CN, consisting of 12 parts of carbon and 14 of nitrogen, enters into combination, acting as if it also were for the time being an element; thus it forms cyanide of sodium, NaCN, or NaCy, and hydrocyanic acid, HCN, or HCy. There are now many thousands of such *radicles* known, of which the groups methyl, CH₃, ethyl, C₂H₅, &c. may be taken as other examples.

Cyanogen is a colourless, poisonous gas, which burns with a purplish flame. It is soluble in water, and can be condensed to a liquid, under a pressure of about four atmospheres (60 lb. per sq. inch). It may be obtained by heating the cyanide of mercury, HgCy₂, when the cyanogen passes off in the gaseous state.

Cyanogen forms poisonous compounds with metals called *cyanides*, of which the best known is the *cyanide of potassium*, a salt of much importance in photography. With hydrogen it forms the deadly prussic or hydrocyanic acid, while it is united with oxygen in cyanic acid. For the properties of *cyanides*, see HYDROCYANIC ACID.

Cyanic Acid is a compound of cyanogen which can hardly be prepared in the free state, owing to its great tendency to decompose. It forms a class of salts called *cyanates*, of which the chief is the cyanate of potash. This salt is produced when cyanogen gas is passed into solution of potash. The formula of cyanic acid is HCyO, that of the potash salt being KCyO.

Cyano'sis (Gr. *kyanos*, 'blue'), lividity of complexion, with fullness of the capillaries and minute veins, especially of the face and lips. A name characteristically applied to the colour in certain cases of congenital disease or malformation of the heart. See HEART.

Cyanotype is a photograph obtained by the use of a cyanide. See PHOTOGRAPHY.

Cyathæa. See TREE-FERNS.

Cybele (called also *Agdistis* and *Dindymene*), an ancient goddess whose worship was universal in Phrygia, and widely spread in Western Asia as that of 'the great mother' or 'the mother of the gods.' She seems to have been a nature divinity, whose worship was attended with wild orgiastic rites, many of which were adopted by the Greeks from the eastern nations. The Greeks, moreover, identified the oriental Cybele with their ancient earth goddess Rhea, whose worship seems to have originated in Crete, where she is associated with the Curetes. Among the Romans she was considered as identical with Ops, the wife of Saturn, and mother of Jupiter. In Phrygia her priests were the Corybantes, who worshipped her noisily with drums, cymbals, and horns, dressed in full armour. The Roman priests of Cybele were often called Galli. In art Cybele is usually represented seated on a throne, adorned with a mural crown, with lions crouching to the right and left, or sitting in a car drawn by lions. See RHEA.

Cycads, or CYCADACEÆ, an order allied to Conifera (see GYMNOSPERMS), but in vegetative appearance rather resembling ferns and palms. The stem, which is externally covered with leaf-scars, may be so short that the crown of leaves arises little above the surface of the ground; more frequently, however, it rises to a height of a few feet, then resembling a tree-fern; and in exceptional cases (e.g. *Cycas media* of Australia) may attain a height of 50 or 60 feet. The foliage-leaves, which develop under the protection of reduced bud-leaves, are usually pinnate, and mostly parallel-veined; but in Cycas we have a middle vein only, and in the curiously fern-like *Stangeria* a mid-vein with lateral branches. The leaves are always of more or less leathery consistence, and sometimes become very hard and spiny at the tips and on the edge. In Cycas

Fig. 1.

a, *Cycas Normanbyana*; b, c, *Cycas media*.

the pinnæ are circinate in bud as in ferns, although the midrib is straight; conversely in *Zamia*, the leaf itself is inrolled, although the pinnæ are straight; in others, however, where both are straight, the pinnæ overlap each other from above downwards, as in the moon-wort fern (*Botrychium*). The stem is of complex internal structure, but is thickened by permanent cambium. It may bear lateral buds on the axils of old leaves, especially in unhealthy plants; and these may fall

off and propagate the plant. In some cases, however, we have an apparent dichotomy, although probably due to branching. Dichotomy of the roots has also been described; this, however, not as a normal development, but due simply to irritation by a fungus-mycelium or a nostoc-like alga, which commonly invests the root, and even penetrates the tissue (see SYMBIOSIS). Yet among those who admit the pathological nature of this, some still regard it as an atavistic reappearance, the last surviving trace of the dichotomy so common among the ancestral cryptogams (see FERNS, LYCOPODIACEÆ).

The exceedingly primitive flowers are found on separate plants, and are respectively composed simply of staminate or pistillate leaves, in both cases usually spirally aggregated as cones. The stamens are reduced and undivided leaves bearing on their dorsal surfaces a usually indefinite number of pollen-sacs, so furnishing a perfectly intermediate form between the sporangium-bearing frond of a fern and the stamens of higher plants. The pollen-grains show a very distinct remnant of the male prothallium.

Passing to the female flowers, we find those at least of *Cycas* to be terminal on the axis, which

Fig. 2.

a, Stamen of *Cycas circinalis*, under surface; b, group of pollen-sacs (Microsporangia); c, pollen-grain of *Ceratozamia*; d, the same germinating; e, carpellary leaf of *Cycas revoluta*, with lower pinnule reduced and bearing ovules; f, stamen of *Zamia integrifolia*.

after flowering resumes vegetative growth, a condition which occurs only as an anomaly or reversion in higher plants (e.g. proliferous roses). The separate carpellary leaves retain more or less distinct traces of vegetative character; thus in *Cycas* the ovules (microsporangia) represent the reduced lower pinnæ; more frequently, however, only two are developed (*Zamia*, fig. 2); but the carpellary leaf is always open, and shows no trace of that still more precocious development of its ovules and arrest of its opening altogether, which would give us the ovary of the higher flowering-plants (see OVARY). On ripening, the cone may fall to pieces, liberating the ovules; in the simpler *Cycas* the separate naked seeds become modified and enlarged into large fruit-like bodies, with an outer fleshy and an inner stony wall. The nucellus is crushed into little space by the growth of the endosperm, which contains the straight embryo with its one (*Ceratozamia*) or two, often unequal (*Cycas*, *Zamia*), cotyledons.

The more vegetative character, both of the flowering axis and of the carpellary leaves, which distinguish *Cycas* from all the other genera, explains the separation of the order by systematists into Cycadeæ and *Zamia*. Among the latter, *Stangeria* of Port Natal is at once distinguished by its pinnate venation; and *Bovenia* of Queensland by its bipinnate

leaves. *Dioon* (Mexico) is characterised by the origin of its ovules on cushion-like modifications of the two parent pinnæ, instead of being simply sessile as in the remaining genera, which are merely distinguished by slight differences in the shape of their cone-leaves. The thirty species of *Zamia* range from Mexico into the Antilles and far into South America. *Ceratozamia* is Mexican, and *Microcycas* Cuban, while *Macrozamia* is distributed over Eastern Australia, and *Encephalartos* is characteristically South-east African. But the widest distribution is that of *Cycas* itself. The best-known species, *C. revoluta* of Japan, is not only widely found both wild and in cultivation in many parts of the Old and New World, but *C. circinalis* of the East Indies, *C. media* and *Normanbyana* of Australia, *C. Seemani* of the Fijis, may also be mentioned as of importance.

Schimper enumerates no less than thirty-four fossil genera, with 278 species. The group appears to have attained its maximum in Triassic and Jurassic times. They are familiar to English palæontologists in the Lias and Oolite especially.

The stem of many cycads contains an abundant starchy deposit, which is used as food in many countries. It resembles sago, and so has frequently led to the confusion of cycads with the true Sago-palms (q.v.). *C. revoluta* yields a coarse sago in Japan and elsewhere; from *Dioon edule* a kind of arrowroot is prepared in Mexico, and from *Zamia pumila*, &c. in the Antilles and Florida; while *Encephalartos* is often called Kafir Bread.

Cyclades. See ARCHIPELAGO.

Cyclamen, a genus of Primulaceæ, including about eight highly variable species, mostly natives of southern Europe. Their thickened and compressed perennial stem half immersed in the ground, their heart-shaped leaves, peculiarly twisted and reflexed corolla-lobes, and spirally reverted fruit-stalks give the genus a peculiar and highly characteristic appearance. They are commonly cultivated on account of the beauty of their flowers; which mostly appear in spring. *C. persicum* is the

Cyclamen persicum.

one chiefly grown in our conservatories; *C. europeum*, not uncommon in gardens, flowers in autumn. The turnip-like stem, despite an extreme acidity which long gave it medicinal repute, is largely eaten by swine in southern Europe, especially Sicily; hence the English name of *Sowbread*.

Cycle (Gr., 'a circle'), in Astronomy and Mathematical Chronology, a period or interval of time in which certain phenomena always recur in the same order. There are two great natural cycles, that of the sun and that of the moon. The solar cycle is a period of twenty-eight Julian years, after which the same days of the week recur on the same days of the year. The lunar or Metonic cycle consists of nineteen years or 235 lunations (see CHRONOLOGY), after which the successive new moons happen on

the same days of the year as during the previous cycle. The number of the year in the cycle of the moon is called the Golden Number (q.v.). The cycle of Indictions (q.v.) is purely arbitrary, its years being fifteen, a conventional number; and the Julian Period, which combines and harmonises all the three others, might be termed the cycle of cycles. The term 'cycle of eclipses' is an instance of the more general use of the word, meaning the period of 223 lunations, within which seventy eclipses recur in the same order and magnitude—viz. twenty-nine of the moon and forty-one of the sun.

Cycling. The early history of cycling—in which generic term the use of all classes of manu- and pedo-motive carriages is now by general consent included—is, like that of ancient Britain, involved in obscurity. As long since as 1818 something in the nature of a bicycle was introduced into England by Baron von Drais, a Frenchman resident at Mannheim, and was known as the Draisene or Célérifère; while velocipedes or manu-motive machines with three or more wheels were in occasional use in England even before that date, one of the earliest being an invention of Richard Lovell Edgeworth (circa 1767). The Draisene consisted of two wheels, about 30 inches in diameter, running one in the wake of the other, and connected by a beam of wood, upon which, midway from each end, was placed a saddle or perch. At the fore-end of the beam an arm-rest was secured, and this, roughly, completed the apparatus. The mode of propulsion was singularly simple: the rider placed his leg over the beam, got into the saddle, and, resting his arms upon the support referred to, pushed the 'dandy-horse' ahead by kicking the ground with his right and left foot alternately; when a certain impetus was attained, he could, were he a skilful rider, cease the kicking process, and allow the machine to proceed until the momentum was exhausted, when he had to commence *de novo*. It is hardly needful to say that the undignified attitude the rider performed assumed was the subject of much ridicule; and it is not to be wondered at that the satire of Cruikshank and his contemporaries effectually killed the hobby-horse of 1818.

The 'Dandy-horse.'

The fashioning of the first practical bicycle (circa 1846) is currently credited to one Gavin Dalzell, a Scotch cooper, who lived at Lesmahagow, in Lanarkshire. It went by the name of the 'wooden horse,' being constructed chiefly of wood; the saddle was low, and the pedal movements or 'stirrups,' which moved backwards and forwards alternately, were connected by iron rods with the cranked axle of the driving-wheel.

The next revival of cycling may be said to date from 1867. A few years previous to this it occurred to an inventive genius, one M. Michaux, to fit to the hobby-horse a pair of pedals by which the front wheel might be revolved with the feet. This, of course, meant that the rider must depend for his balance upon some means

whereby the relative positions of the two wheels might be varied at will; in other words, some method whereby the base of the machine might be changed at pleasure. To this end, a transverse handle was affixed to the front wheel, which admitted of its being turned even to a right angle. This new-comer was known as the bicycle, but is now irreverently alluded to in all quarters as the 'boneshaker'—probably because it was made of wood, and shod with iron tyres instead of rubber, while springs were often conspicuous by their absence.

The boneshaker craze was a serious one; it affected all classes of society, but chiefly—in consequence of the cost of the article—the middle and upper ranks; in witness whereof, the illustrated papers of 1867-69 contained more than one woodcut showing the Prince Imperial upon his boneshaker in the Tuileries. One of the earliest of Michaux's bicycles found its way to Mr Charles Spencer's gymnasium in London in 1868. So little was to be gained, and so much was to be lost—particularly in the way of appearances—by 'boneshakerism,' that in a few years it promised to become a lost art, when, happily, the inventive genius of an Englishman, whose identity is open to question, supplied the missing link—the rubber tyre—which, with the suspension wheels and steel framing introduced at a later period, made the modern bicycle. From the bicycle the tricycle was early evolved, chiefly through the instrumentality of James Starley, of Coventry, until the types of machines at present obtainable are practically endless.

The utility of the cycle is proved beyond all question. It is asserted on the best authority that a person of average capabilities can upon it travel at least three, and frequently six, times as far as he can walk in a day, and this with even less fatigue; while the possibilities of the machine in able hands will be admitted, when it is pointed out that a mile has been ridden upon a bicycle in less than two minutes and a half, and that 21 miles have been traversed well inside the hour, 50 miles in a little over two hours and a half, and 100 miles in considerably under six hours. The figures for longer distances are just as startling, for 300 miles have been covered in a day, and the road from Land's End to John o' Groat's—roughly, 900 miles—has been accomplished in five days one and a half hour!

But the utility of the cycle is further proved by facts other than those given; it has become the poor man's carriage, and the rich man's hobby in more senses than one. Royalty disports itself, at anyrate in quasi-publicity, upon it, and the nobility and gentry make no secret of their love of the wheel. Clergymen visit their parishioners; medical men their patients; and tens of thousands of the middle classes transact their business or follow their pleasures by its means; while it is next to impossible to pass through any of the streets of our chief towns without seeing that the cycle, in some one of its numerous shapes, is ably ministering to the wants of the community. It was estimated that in 1888 not less than 500,000 machines were in use, a fact that will justify the assertion that cycle-making has become a very important industry.

So general has cycling become, that there are in existence in Great Britain alone at least twenty cycling publications, varying from weeklies to annuals, while roadbooks and handbooks innumerable have already been put upon the market.

As with most other sports or pastimes, cycling is strong in a clubdom of its own. Hundreds of local clubs exist in different parts of the country, while acting in concert with them is the largest of all, the Cyclists' Touring Club, whose headquarters are

at 139 and 140 Fleet Street, London. The C. T. C., as it is familiarly called, was not the forerunner of the local clubs to which reference has been made, for some of these existed three or four years before it, but it was called into existence in 1878 for the purpose of encouraging and promoting touring, as its name implies. To this end it has appointed at one fixed tariff some hotel—often the leading one—in every town as headquarters. It has also appointed a member in nearly every town to act as consul—in other words, to be a guide to visiting clubmen; in addition to which it has nominated the most competent mechanic the place possesses to repair machines at moderate prices in case of breakage. By the introduction of a specially suitable and durable uniform; by the compilation of roadbooks and maps for the Continent, as well as for Great Britain; by agitating for better roads, for finger-posts and milestones; and in countless other ways it has benefited cyclists and cycling; and that its programme is a popular one, will be apparent when it is explained that it already possesses over 22,000 members. It publishes an official *Gazette*, which, consisting of some forty to fifty pages, is sent gratis to every member once a month, as well as an official handbook with full details of the arrangements made in the different parts of the country for the convenience of its members. The benefits of membership are all obtainable for a nominal sum annually. The C. T. C. is international in its character, nearly a dozen prosperous divisions having already been established in the United States, in Canada, and upon the Continent.

Cycling possesses also a National Cyclists' Union that looks after the legislative side of the sport; that frames and endeavours to uphold the amateur definition; that pledges itself to oppose the introduction of prohibitive restrictions; that holds the amateur championships; and that in many other ways does a large amount of good for wheeldom. The headquarters of this body are at 57 Basinghall Street, London, E.C., and the subscription for members not belonging to a local club affiliated *en masse* is five shillings. There are branches of the N. C. U. in Scotland, and Ireland has its Cyclists' Association.

For many years cycling was practised in England in the face of much ridicule from the general public, and hostility from other sections of the road-using community; while ingress to the parks was denied its votaries. These prejudices have, however, happily been overcome; by the instrumentality of the C. T. C. and the N. C. U. before referred to, nearly all these restrictions have been removed, and, speaking broadly, a cycle is at liberty to enter and use the inclosures to which other public vehicles are given access. Similarly, through the exertions of the C. T. C., the powers hitherto possessed by courts of quarter session and corporations under the Highways Amendment Act of 1878, and the Municipal Corporations Act of 1882, have by the Local Government (England and Wales) Act, 1888, been taken from them. Cycles have been declared to be carriages within the meaning of the Highways Acts, entitled to all the benefits, and subject to all the penalties (tax-paying excepted) applicable to other carriages, while the anomalous and conflicting bylaws hitherto in force were, on 1st April 1889, superseded by a statute law which runs as follows:

Local Government (England and Wales) Act, 1888, sect. 85.—(1) The provisions of sect. 26, sub-sect. 5, of the Highways and Locomotives (Amendment) Act, 1878, and sect. 23, sub-sect. 1, of the Municipal Corporations Act, 1882, in so far as it gives power to the council to make bylaws regulating the use of carriages herein referred to, and all other provisions of any other public or private acts,

in so far as they give power to any local authority to make bylaws for regulating the use of bicycles, tricycles, velocipedes, and other similar machines, are hereby repealed; and bicycles, tricycles, velocipedes, and other similar machines are hereby declared to be carriages within the meaning of the Highway Acts; and the following additional regulations shall be observed by any person or persons riding or being upon such carriage: (a) During the period between one hour after sunset and one hour before sunrise, every person riding or being upon such carriage, shall carry attached to the carriage, a lamp, which shall be so constructed and placed as to exhibit a light in the direction in which he is proceeding, and so lighted and kept lighted, as to afford adequate means of signalling the approach or position of the carriage. (b) Upon overtaking any cart or carriage, or any horse, mule, or other beast of burden, or any foot-passenger, being on or proceeding along the carriage-way, every such person shall, within a reasonable distance from and before passing such cart or carriage, horse, mule, or other beast of burden, or such foot-passenger, by sounding a bell or whistle, or otherwise, give audible and sufficient warning of the approach of the carriage. (2) Any person summarily convicted of offending against the regulations made by this section, shall, for each and for every such offence, forfeit and pay any sum not exceeding forty shillings.

Cycle-racing, by both amateurs and professionals, has developed into a fine art, and bids fair to rival in popularity all but horseracing. Cinder-paths specially constructed for the purpose exist in nearly all the more important centres, and amateur race meetings are of frequent occurrence during the summer season; but Leicester, Wolverhampton, North Shields, and Coventry are the places chiefly noted for contests among the professional fraternity.

The practice of camping out under canvas is one which seems to have commended itself to cyclists in a marked degree. The habit originated at the North of England Cyclists' Meet, held annually at Harrogate; and it has been perpetuated not only by Northerners, but by Southerners as well, the latter usually selecting Mid-Surrey as their camping ground.

Apart from the marvellous modern records to which previous reference has been made, some notable distances were covered even upon the earlier and more imperfect forms of machines. Among them should be mentioned the one from London to Bath by David Stanton, who was credited with covering the 106 miles in 8 hours 28 minutes on the 17th August 1874, as also the year's record of Mr E. Tegetmeyer of the Belsize Bicycle Club, London, who claimed to have ridden over 10,000 miles in a single season.

From time to time the cycling world has been startled by announcements to the effect that electric and steam tricycles are about to be put into the market to revolutionise the pastime and sport. These predictions have, however, never been fulfilled, nor is it very probable or desirable that they should be. The inseparable difficulty that attaches to the construction of an electric tricycle is the excessive weight which must of necessity be carried, until accumulators have been established upon all the roads likely to be frequented by cyclists; while apart from the weight and dirt that would attach to the use of a steam-engine, the condition of the law at the present time is such that a steam-velocipede is held to come within the category of road locomotives, the rules governing which include one to the effect that no greater speed than four miles an hour may be maintained, and that any such locomotive must be under the control of

at least three persons, and preceded by a man on foot carrying a red flag at least 20 yards ahead! See *Parkyn v. Priest*, Law Reports of Queen's Bench Division, 317.

Cycling is not only extremely popular among the sterner sex, but ladies innumerable have taken to the pastime. The Cyclists' Touring Club before referred to possesses nearly 1000 lady members. In England the tricycle is their favourite machine.

Many devices for reducing the labour required to propel a machine over heavy roads and up steep gradients have from time to time been devised. Probably the best of these is the crypto-dynamic gear manufactured by the Crypto Cycle Company, 64 City Road, London, E.C. This invention has marvellously lightened the labour in connection with cycling in the case of elderly persons and invalids, but as a rule a muscular rider is content with one speed affixed to a light machine, upon which he is able to make even better progress than upon the necessarily heavy crypto-gear article. A simple method of ascertaining how a machine is geared is to multiply the diameter of the driving-wheels by the number of teeth in the lower cog-wheel, and then divide by the number of teeth in the cog upon the main axle—e.g. a 40-inch wheel has twenty teeth upon its lower cog-wheel, and fifteen upon the upper; this gives a gearing of 53½ inches.

'Trick riding' is an art which American riders assiduously practise, and in which they naturally excel; so much so, that many 'professors' thereof have from time to time visited Great Britain and continental Europe to exhibit their prowess to the multitude. Trick riding aside, however, it is generally conceded that the typical Englishman makes the most enthusiastic cyclist; partly because the bicycle was first systematically made and ridden here, and partly because he possesses an inbred love of athletics. Coventry, Birmingham, Nottingham, Wolverhampton, London, and to a smaller extent other important places, are interested in the manufacture of machines, while the first named has happily been enabled to substitute for the fast-decaying or depressed industries of ribbon-weaving and watchmaking, for which she was long celebrated, the designing and manufacturing of cycles, which find employment for thousands of hands. It is estimated that the capital invested in the cycle trade is considerably over a million sterling.

The types of machines in current use are the ordinary bicycle, the dwarf rear-driven safety bicycle or some modification thereof, the front-steered tricycle, the carrier or tradesman's tricycle, tandem bicycles, both ordinary and dwarf, tandem front-steered bicycles, and invalid pedo- or manu-motive cycles; but numerous machines coming within none of these categories are met with from time to time. The fashion in this respect has necessarily changed with great rapidity, seeing that it is only within the last few years that really skilled and competent engineers and mechanics have turned their attention to the perfecting of the cycle. The numerous improvements, together with the impracticable ideas of the ever-present visionary, are generally shown annually at the Stanley exhibition, a fixture which takes its name from the London club bearing this title.

Among recent developments in connection with the cycle have been its adoption by some of the leading London dailies to convey special editions to the various railway termini, and the use of the cycle by the postal authorities; while pregnant with much greater import to all concerned is the official adoption of the two-wheeled machine by the military authorities. With this object in view, the various volunteer corps at present in existence

were in 1887 authorised by the War Office to form cycle contingents within their ranks, while a special cyclist corps, known as the 26th Middlesex, has been called into existence. These various formations can hardly be considered to have as yet won the place they seem destined to occupy, but they have sufficiently demonstrated their capabilities to cause the highest military authorities to entertain a very hopeful opinion of their value in the near future.

In America, where cycling is becoming increasingly popular, there are a large number of flourishing cyclist clubs in the large cities, such as New York, Brooklyn, Philadelphia, Chicago, and Washington; and the club-houses there are more complete and better equipped than in Great Britain. The League of American Wheelmen had in 1888 about 12,000 members, while it was estimated that there were more than 60,000 cyclists in the United States. Washington, with its miles of asphalted streets as smooth and level as a floor, in 1888 claimed to have 4000 wheelmen and 300 lady tricyclists. One American cyclist is credited with having ridden 8000 miles in 1887, and another 7000 miles. More conspicuous is the tour round the world, undertaken by Mr Thomas Stevens, who, starting from San Francisco on the 22d of April 1884, travelled to Boston, then shipped to England, again embarked for the Continent, and passed through Germany, Austria-Hungary, the Balkan Peninsula, Asia Minor, Armenia, Persia, Afghanistan, India, and China, whence he sailed for his starting-point. This was a ride occupying three years, and involving an enormous amount of endurance, pluck, and energy. As might be expected, manufacturing enterprise has kept pace with the demand; and America is also well supplied with cycling literature.

Utilitarian to a high degree, health-giving to a measure that causes many of the leading medical men to recommend its adoption to both sexes in nearly all cases where organic disease is absent, cycling, if rationally pursued, may unquestionably be regarded as one of the boons and blessings of the 19th century.

See *Cycling*, by Viscount Bury and G. L. Hillier (Badminton Library series, 1888); Spencer's *Bicycles and Tricycles, Past and Present* (1883); and *Cycle Directory* (1884); Dr Benjamin Ward Richardson's *Tricycle in Relation to Health and Recreation* (1885); Stables's *Health upon Wheels* (1885); *Pleasures and Advantages of Cycling* (1887); *Art and Pastime of Cycling*; Stevens's *Around the World on a Bicycle* (1887).

Cycloid (Gr., 'circle-like'). If a circle roll along a straight line in its own plane, any point on the circumference describes a curve which is called a cycloid. This is the most interesting of what are called the transcendental curves, both from its geometrical properties and its numerous applications in mechanics. In dynamics, for example, we find that a heavy particle descends from rest from any point in the arc of an inverted cycloid to the lowest point in the same time exactly, from whatever point of the curve it starts. This is sometimes expressed by saying that the cycloid is the *isochronous* (Gr., 'equal-time') curve. The body having

The Cycloid.

reached the lowest point, will, through the impetus received in the fall, ascend the opposite branch of the curve to a height equal to that from which it fell, and it will employ precisely the same time in ascending as it did in descending. It is clear that if a surface could be procured that would be perfectly smooth and hard, the cycloid would thus present a

solution of the perpetual motion. The line AB, which is called the base of the cycloid, is equal to the circumference of the generating circle; the length of the curve ADB is four times CD, the diameter; the evolute of any cycloid is a similar curve of equal length; and the surface between the curve and its base is three times the area of the circle CD. In any position EPF of the generating circle, AE is equal to the arc EP; PE is the normal at P and = half the radius of curvature; PF is the tangent to the curve at P.

Cycloid-scales, fish-scales with a round un-toothed posterior margin and concentric lines parallel to the latter. See SCALES, FISHES.

Cyclone (Gr. *kyklos*, 'a circle'), a circular storm of great force, which, extending over an area of perhaps 500 miles, and revolving round a calm centre, advances at the rate of from 20 to 30 miles an hour. See STORMS.

Cyclopædia. See ENCYCLOPÆDIA.

Cyclopes (Gr. *kuklōpes*, 'the round-eyed'), in the incoherent traditions of a gradually developing mythology, fall into three groups. (1) The Homeric Cyclopes, a wild, lawless, and impious race of giants, inhabiting the sea-coasts of Sicily, the most prominent of whom is Polyphemus (q.v.). Although Homer does not directly call them one-eyed, yet he expressly terms Polyphemus such, and the later poets attribute his peculiarity to the rest. (2) The three Cyclopes mentioned by Hesiod: Brontes, Steropes, and Arges, each having one eye in the middle of his forehead; these were sons of Uranus and Gaea, belonged to the race of Titans, and forged thunderbolts for Zeus. Hurlled into Tartarus by their father, but delivered by their mother, they helped Kronos to usurp the government of heaven. Kronos, however, in his turn, threw them back to Tartarus, from which they were again released by Zeus, whose servants they now became. Finally, they were slain by Apollo, because they forged the thunderbolt with which Zeus killed Æsculapius. Later tradition placed their workshop in Mount Etna, or in the volcanoes of Lemnos and Lipari, and made them the slaves of Hephestus. (3) The Cyclopes mentioned by Strabo as a people who had come from Thrace or Lycia to Argolis, and were distinguished for their skill as builders.

CYCLOPEAN WALLS is a name given to masonry built of large, irregular stones, closely fitting, but unhewn and uncemented. They were attributed to Strabo's Cyclopes, who were probably mythical, and many of them still exist in Greece (as at Mycenæ and Tiryns), Italy, and elsewhere. More probably the so-called Cyclopean walls were built by some ancient race, perhaps the Pelasgians (q.v.), at a period long anterior to the historical civilisations of Greece and Rome.

Cyclops, a genus of small fresh-water crustaceans, type of a family (Cyclopidae) in the order Copepoda. They are popularly included under the wide title of 'water-fleas.' Various species are common as active swimmers in fresh-water pools or slow-flowing brooks, and a few forms have been recorded from the sea. Like other copepods, cyclops has an elongated body, without a shell, with four forked thoracic feet and a five-jointed abdomen. The head-region is not distinct from the first ring of the thorax; there is a pear-shaped segmented body and a long abdomen; both pairs of antennæ are long, and in the male the anterior pair form claspers; the mandibular and maxillary palps are degenerate; and a heart is said to be absent. The average length of the commonest species is from 2 to 3 millimetres; the males are generally smaller than the females. A very marked feature, to which the name refers, is the single median eye, usually bright crimson and sparkling like a gem;

and not less noticeable are the two large egg-bags carried by the females. They eat both animal and vegetable matter, and are very prolific. See CRUSTACEA, WATER-FLEA.

Cyclopteris, a genus of fossil ferns met with in Devonian and Carboniferous strata. The leaflets are somewhat rounded or wedge-shaped, and have no midrib, the nerves spreading from the point of attachment.

Cyclorama. See PANORAMA.

Cyclosis (Gr., 'circulation'), the name employed to designate certain movements of the contents of cells in plants. See VEGETABLE PHYSIOLOGY.

Cyclostomata (literally, 'round mouths'), a class of vertebrates often included along with fishes, but separated from them by some fundamental divergences. Hag-fish (Myxine) and Lamprey (Petromyzon) are the two most familiar examples, and are types of the two orders into which the Cyclostomata (or Marsipobranchii) are divided.

Cydnus, a river of Cilicia, rising on the south side of the Taurus range, and flowing through a rich and level country, past the city of Tarsus, and a broad lagoon, now choked up with sand, into the sea. Its water was famous for its clearness and coldness, and was supposed to be efficacious against gout and nervous diseases. Alexander nearly lost his life through an illness brought on by bathing in it when overheated.

Cydonia. See QUINCE.

Cygnets, a young Swan (q.v.).

Cylinder (Gr., 'a roller'), a well-known solid whose cross-section at any point of its length gives always the same circle; or, mathematically, a solid

generated by the revolution of a rectangle about one of its sides, which line is called the axis of the cylinder. That, the typical cylinder, is frequently called *right*, and if cut by two parallel planes not perpendicular to the axis, the result is an *oblique* cylinder, with elliptical ends or sections. The term has also been generalised to include a solid generated by a line moving parallel to a fixed direction while tracing any fixed closed curve. In all cases the content of the cylinder is found by multiplying the number of square units in the base by the number of linear units in the altitude, which is

the perpendicular distance between the two ends. The area of the convex surface is equal to the product of the circumference of the end, and the length of the generating line. To this must be added the areas of the two ends, to get the whole surface of the cylinder.

Cyma. See MOULDING.

Cymbals are a pair of thin round metal plates, with a hollow part in the centre, in which a leather strap is fastened for holding in the hand. They are instruments of percussion, which, when struck one against the other, produce a loud harsh sound of no fixed pitch. They are of very ancient origin, and were used by the Greeks in the worship of Cybele. The best cymbals are those made in Turkey and in China. Attempts to discover and imitate the composition of the metal have all failed, the nearest approach to it hitherto discovered being an alloy of 80 parts of copper to 20 of tin. The cymbals generally play the same part as the bass drum, and in orchestras they are played on by the same performer, one cymbal being fixed on the drum, the other held in one hand, while the other hand wields a drumstick. Cymbals are, however, essentially military instruments.

Cymbeline, an ancient king of Britain in a well-known play of Shakespeare called by his name. By his first wife he had a daughter, Imogen, who married Posthumus Leonatus. His second wife had, by a former husband, a son named Cloten. Shakespeare borrowed the name from the half-historical Cunobelinus in Holinshed's *Chronicle*, of whom several coins are extant.

Cyme, a term employed in Botany to designate those forms of inflorescence which are *definite* or *centrifugal*—i.e. in which the main axis ends in a flower, but bears one or more lateral branches which again terminate in flowers, but not before producing secondary branches which continue the same process as far as growth permits. The various forms and varieties of cyme, which are not only of great morphological interest, but frequently also of systematic importance—e.g. Caryophyllaceæ, Labiatae, &c., are described under Inflorescence (q.v.).

Cymry. See CELTS and WALES.

Cynanchum, a genus of Asclepiadaceæ, of which some species have been used medicinally—e.g. *C. monspeliacum* as a violent purgative, the so-called Montpellier Scammony, and *C. vincetori-cum*, formerly in repute as an antidote to other poisons. The Indian *C. extensum* yields fibre, and *C. oratifolium* of Penang, caoutchouc.

Cynewulf, an Anglo-Saxon poet of whom almost nothing is known. He has handed down his name wrapped up in runes in his poems *Christ*, *Juliana*, and *Elene*. It seems most probable that he was a Northumbrian, but Wülcker holds that there is no sufficient evidence for this belief. Dietrich identifies him with Cynewulf, the Bishop of Lindisfarne (737–80), but Ten Brink refuses to admit the identity between the two. Cynewulf's principal works may be referred with some degree of confidence to the second half of the 8th century. He belonged to the guild of wandering glee-men, possessed some learning, and was popular with his contemporaries. His poems are aglow with fervid Christian feeling, and show rich imagination and power of language. The influence of Aldhelm is distinctly traceable both in the themes and in their treatment. The chief works are a collection of poetical riddles; the *Christ*, a subject borrowed from the old Latin homilies, in which his birth, his ascension, and the judgment are described, the last being particularly effective; *Andreas* and *Elene*, two religious epics; *Guthlac* and *Juliana*, versified lives of those saints.

Cynics, the name applied to a school of Greek philosophers, who were distinguished mainly for their morose and snarling ethics, and their ostentatious contempt of the ordinary pleasures of life. The name is due either to *Cynosarges*, the place where Antisthenes, the founder, taught; or to their dog-like (*kynikos*) contempt for conventional manners. For their peculiar opinions, see articles ANTISTHENES, DIOGENES, MENIPPUS, &c.

Cynips. See GALL-FLY.

Cynodon, a genus of grasses of which one species, *C. dactylon*, is of peculiarly wide distribution, not only ranging from its British habitat on the sandy shores of Cornwall to fringe those of North America and the West Indies, where it is known as Bermuda grass, but also forming (on account of its great power of resisting drought) the most important fodder and pasture grass of India, where it is known as *Dhob*, *Doorba*, &c. Its creeping roots, and those of its congener, *C. lineare*, have medicinal virtues, and are sometimes used as a substitute for sarsaparilla.

Cynomorium, a genus of the curious parasitic order Balanophoraceæ (see PARASITISM, VEGE-

TABLE). *C. coccineum*, a plant of a strange fungus-like appearance, is found in the islands of Malta and Gozo. It was long known as *Fungus Melitensis*, and enjoyed the highest reputation as a styptic, besides being used as an astringent in dysentery and other maladies. These uses, however, depended on the doctrine of signatures alone, its scarlet colour and blood-like juice being interpreted as providential indications of its curative destination for all injuries or diseases accompanied by bleeding. So high a value was set upon this plant, that the knights of Malta took it under their particular care as one of their choicest possessions; it was carefully gathered and deposited in a government office, from which the grand-master sent it to friendly sovereigns, and to the hospitals of the island. Up to a recent date a keeper of the rock which most abundantly produces the plant was still appointed by the British government.

Cynomorium coccineum, growing upon the roots of (a) its phanerogamous host; b, c, d, different stages of development.

plant was still appointed by the British government.

Cynomorpha (literally, 'dog-shaped'), the lower division of Old-World or Catarrhine monkeys. Baboon (*Cynocephalus*) and Magot (*Macacus*) are good examples. See **MONKEYS**.

Cynoscephalæ ('dog's heads'), two hills near Scotussa, in Thessaly, where Flaminius defeated Philip of Macedon, 197 B.C.

Cynosure (Gr. *kynosoura*, literally, 'the tail of the dog'), the Greek name for the constellation of the Little Bear, which contains the pole star, by which the Phœnician mariners steered their course, while the Greeks steered by the Great Bear. The name is metaphorically applied to anything that attracts attention, or to which all eyes are turned. Its use, with this meaning in reference to a lady, in Milton's classic poems *L'Allegro* and *Comus*, will be remembered. In the Greek mythology, Callisto, daughter of Lycaon, king of Arcadia, was changed into the Greater Bear (called also *Helice*), and her son, Arcas, into the Lesser (called also *Cynosura*). —The Dog's-tail Grass is called *Cynosurus*.

Cyperaceæ, the order of reeds and sedges, are nearly akin to grasses, but easily distinguished by their solid, unjointed, generally triangular stems, undivided leaf-sheaths, and absence of paleæ. There are about 2000 species, widely distributed throughout all climates, but more especially in temperate and cold regions, and in marshy soils, of which they often take almost entire possession. Dry and rough in texture, they furnish only the very poorest constituent of fodder or hay, nor with few exceptions (see **BULRUSH**, **CYPERUS**, **PAPYRUS**, **CAREX**, **REED**) have they any other economic uses.

Cyperus, a large genus of Cyperaceæ, chiefly tropical. The tubers or root-stocks of some species are edible, notably *C. esculentus*, which is cultivated in southern Europe. Others have long been used in medicine and in perfumery—e.g. *C. longus*. *C. textilis* of South Africa yields fibre. In America,

C. hydra, a tuberous species, is an exceedingly troublesome weed in cultivated lands, such as cotton-fields.

Cy-près, which, roughly translated, means 'as near as possible,' is applied to a well-known doctrine in the law of charitable trusts in England. This doctrine is to the effect that where a trust mentions a general purpose to which money is to be applied—e.g. higher education, and also some particular method—e.g. payment to an institution which ceases to exist, the court will direct the application of the money in some other particular method, as near as possible to the one mentioned, and consistent with the general purpose. The doctrine is closely connected with another—viz. that where only a general charitable intention is expressed—e.g. relief of the poor, the court will devise some particular scheme, and will not hold the trust void for uncertainty. These doctrines also exist in Scots law, though not under the name of cy-près. The expression is also applied to a principle on which the court acts, so as to avoid illegality in settlements of property. In the United States it is held that the equity courts cannot make valid charities which are uncertain, but where charitable trusts have once been set agoing, they will prevent the trust from being defeated by change of circumstances.

Cypress (*Cupressus*), a genus of evergreen coniferous trees or shrubs, with small generally appressed and imbricated leaves, and with almost globular cones, the peltate woody scales of which bear numerous hard winged seeds. The best-known species is the Common Cypress (*C. sempervirens*), a native of the Mediterranean countries, Asia Minor, and Persia, whence it has been introduced into mild localities in Britain. It has two main varieties, one (var. *horizontalis*) with spreading or drooping branches, forming a flat-topped tree, the other (var. *fastigiata*) with closely appressed branches like a Lombardy poplar, and capable of attaining a height of 100 feet. On account of its sombre colour yet upward aspect, this variety has been planted since classic times around temples and

Branch of Cypress.

tombs; in this latter aspect, the drooping variety often took a marked place. The Greeks and Romans put its twigs in the coffins of the dead, they used it to indicate the house of mourning, and planted it about burial-grounds, as is still the custom in the East. The vast Turkish cemeteries, of which European and American cemeteries may be regarded as imitations, are thickly planted with the poplar-like variety, and are often growing into sombre forests. The wood of the cypress is yellow or reddish, and has a pleasant smell. It is very hard, compact, and durable; the ancients reckoned it indestructible; and the resin which it contains gives it the property of resisting for a long time the action of water. It is not liable to the attacks of

insects, and being also of beautiful colour and easy polish, was formerly much esteemed for the finest kinds of work in wood, even Cupid's arrows being traditionally made of cypress-wood. Some believe that the cypress is the true cedar-wood of Scripture, and it has also been identified by commentators as the *gopher wood* of Noah's ark. In any case, cypress and cedar have been prized for shipbuilding in the East from the earliest times. The doors of St Peter's at Rome, made of cypress, lasted from the time of Constantine the Great to that of Pope Eugene IV., above 1100 years, and were perfectly sound when at last removed, that brazen ones might be substituted. Medicinal virtues were formerly ascribed both to the wood and seeds of the cypress, and oriental physicians have long been wont to send patients suffering from chest-diseases to breathe the air of cypress-woods, thus curiously anticipating the western practitioner. The resin has also had medicinal repute from classic times, while the Turks still use also the fruit and bark. The ethereal oil of cypress-wood was also used by the ancients for embalming, and the coffins of mummies were made of the wood.

More common in cultivation in Britain is the extremely hardy *C. Lawsoniana*, a native of Upper California, but of which there are now many varieties. *C. fragrans* and *macrocarpa*, from the same region, are also often cultivated, together with *C. thyoides*, the White Cedar of Canada, and *C. nutkaensis* (*Thuopsis borealis*), the valuable Yellow Cypress of Alaska and Oregon. Among tenderer species are occasionally seen *C. lusitanica*, the Portugal Cedar, or Cedar of Goa, a native of Goa naturalised in Portugal; *C. torulosa*, from the Himalaya; *C. excelsa* and others, from Mexico. The pretty little *Retinosporus* of Japan, now so common in cultivation, forms for some authors only a sub-genus of cypress, or with some of the preceding (e.g. *C. nutkaensis*) are separated on account of their two-seeded fruit-scales, as the genus or sub-genus *Chamaecyparis*.

Cyprian, St. Thascius Cecilius Cyprianus, one of the most illustrious Fathers of the church, was born about 200 A.D., probably at Carthage, of heathen parents. After being a teacher of rhetoric at Carthage, he became a Christian, and was baptised probably in 245 or 246. Immediately afterwards he gave to the poor the greater part of his considerable fortune, and devoted himself assiduously to the study of Scripture and the writings of the church's teachers, especially Tertullian. After being successively a deacon and presbyter, he was made a bishop in 248. His zealous efforts for the restoration of strict discipline soon brought him a host of enemies. In the Decian persecution, which at Carthage was especially severe, the heathen people cried incessantly '*Cyprianum ad leonem!*' but Cyprian sought safety in flight, in his retirement still caring for his flock with the help of two *vicarii*, and distributing large sums of money among the poor. He returned to Carthage in 251, and the rest of his life was a constant struggle to hold the balance between the two extreme parties—the adherents of Felicissimus and Privatus on the one hand, who favoured laxity in the treatment of the *Lapsed* (q.v.), and those who would exercise the utmost severity, such as the followers of Novatianus, on the other. Cyprian was excommunicated by the Roman bishop Stephanus for his opposition to the Roman view of the validity of lay baptism. He rejected this doctrine as making the sacrament merely mechanical, and laid stress on the personal piety of the priesthood and their special authority for its administration, asserting that baptism could only be a reality when accompanied 'with the full and entire faith both of the giver and receiver.' At a synod at Carthage in 256,

he maintained that the Roman bishop, spite of the primacy of Peter, could not claim a judicial authority over other bishops. His principle, that 'a priest of God, holding the gospel and keeping the commandments of Christ, may be put to death, but cannot be overcome,' Cyprian himself illustrated, on the 14th September 258, when he suffered martyrdom under the Emperor Valerian.

His character and conduct have been very variously judged. Both in his own and later times he has been accused of cowardice and pride. His zeal, fidelity, and self-denial were undeniable, and his courageous martyrdom frees him from the reproach of cowardice. His writings are all directed to practical ends. The earliest complete editions of his works are by Erasmus (Basel, 1520), Pamelius (Antwerp, 1568), and Bishop Fell (Oxford, 1682); and the best is that of Hartel (3 vols. Vienna, 1868-71). They consist of a collection of *Epistles*, and a series of treatises, which are themselves pastoral epistles of a bishop to his flock (see the translation by Wallis, 2 vols. 1869). His best-known work, *De Catholica Ecclesie Unitate*, laid the foundation of the hierarchical conception of the church. Cyprian holds that the unity of the church is founded upon the episcopate, not of Rome, but of the universal Church. In the Church alone can salvation be obtained ('he cannot have God for his Father, who has not the church as his mother'). See the Lives by Poole (Oxford, 1840), Peters (Ratisbon, 1877), and Fechtrop (Munich, 1878); also Salmon in *Hermathena* I. (Dublin, 1873).

Cyprinidae ('carps'), a large family of fresh-water bony fishes in the order Physostomi, with open swim-bladders. Barbel, Bream, Carp, Chub, Dace, Gold-fish, Gudgeon, Minnow, Roach, Tench, are familiar examples. They are distinguished from their neighbours by their small toothless mouths, naked head, usually scaled body, and by the absence of the adipose fin. The family includes over a hundred genera, and eight times as many species. They are widely distributed, most abundant in north temperate regions, absent from Australia and South America. They are voracious, very fertile, and frequently hibernates. See CARP, &c.

Cyprinodontidae ('toothed carps'), a family of small bony fishes in the order Physostomi, with open swim-bladders. They are allied to carps (Cyprinidae), but the mouth bears teeth, the head and body are scaled, and there are never barbules. The family includes twenty genera and over a hundred species, widely distributed in the warm and tropical zones, both fresh-water and marine. They are in most cases viviparous, and the males are generally smaller than the females. The majority are carnivorous, but several forms are known as mud-eaters. Cyprinodon, Fundulus, Anableps (q.v.), and Puccilia are the more important genera.

Cypripedium, or SLIPPER-ORCHIS. See ORCHIDS.

Cypris, a very common small fresh-water crustacean, type of a family (Cypridae) in the order Ostracoda. Like other ostracods, this small 'Water-flea' (q.v.) has an unsegmented body, seven pairs of appendages, a rudimentary abdomen, and a bivalve mollusc-like shell inclosing all. The shell of cypris is dainty and elastic; the posterior antennae bear a long tuft of bristles on their second joint; the second pair of maxillae have a small gill-appendage; the posterior limbs are very irregular. Various species of cypris are readily found in fresh-water pools, in which they swim very actively; the largest form (*C. pubera*) measures 2.7 millimetres in length. The reproductive relations are of some general interest. Some species—e.g. *C.*

fusca and *C. pubera*, reproduce parthenogenically in summer and autumn, the males being rare and transient; while in others—e.g. *C. ovum*, the males are found throughout the year, and parthenogenesis seems not to occur. The eggs are usually laid in masses on stones and water-plants; in *C. pubera* the egg remains as such throughout the winter. The males are remarkable for a peculiarly long and complex syringe-like modification of the reproductive duct. The adults are said to be able to survive desiccation, and this is certainly true of the eggs. Some species are very abundant as fossils in fresh-water strata—e.g. *C. waldensis*, in the English Wealden. See CRUSTACEA.

CYPRUS (Gr. *Kypros*, Turk. *G'ib'is*, Fr. *Chypre*, Ital. *Cipro*) is situated in the north-east of the eastern basin of the Mediterranean, S. of Asia Minor, and W. of Syria, between 34° 30' and 35° 41' N. lat., and 32° 15' and 34° 36' E. long. The distance from Cape St Andreas, the north-easternmost point of the island, to the mainland of Syria near Latakia is about 52 geographical miles, while Cape Kormakiti on the north of the island is only 35 miles from Cape Anamur in Cilicia. Larnaca is nearly 1000 miles east of Malta, and little over 200 from Port Said and the entrance to the Suez Canal, while Limassol is somewhat nearer to both. The familiar shape of the island was likened by the ancient Greeks to that of a deer's skin, of which the long and narrow peninsula of Carpas represented the tail. The extreme length is about 140 miles, of which 40 consist of this Carpas peninsula; the extreme breadth is 60 miles; and the area is 3707 sq. m., or a little larger than Norfolk and Suffolk together. There are two principal ranges of mountains which form the most remarkable natural feature of the country. The northern range extends from Cape St Andreas, at the extreme east of the island, almost as far as Cape Kormakiti, some 20 miles to the west of Kyrenia. The highest mountains of this range, Buffavento (3240 feet), St Hilarion (3340), and Pentedaktylon (2480), are situated almost immediately north of Nicosia, and appear, owing to the extreme clearness of the atmosphere, to rise almost from the outskirts of the town, from which they are distant fully 12 miles. To the south of this range, and extending from Salamis to Morfu Bay, is the great Messorian plain, once famous for its crops of cereals. Of late years, owing to the abandonment of irrigation-works, the decay of wells, and the absence of any system of water storage, its fertility has greatly fallen off, and in 1887, owing to a deficient rainfall, there was a scarcity almost amounting to famine. The western range occupies the greater part of the western and south-western districts of Cyprus, and extends to the east as far as the isolated peak of Santa Croce or Stavrovouni, only 12 miles to the west of Larnaca. The highest mountain of this range is Mount Troödos (6352 feet), of which one of the peaks bears the classic name of Olympus.

On the slopes of Troödos, under gigantic pine-trees, is pitched the camp where troops from Limassol spend a part of the summer months under canvas, and where the brigade of guards recruited their strength in the autumn of 1885 after their sufferings in Egypt. Cyprus has practically no harbours; Larnaca and Limassol, the chief seaport towns, are open roadsteads, unprotected against all but northerly winds, with such shallow water that steamers are obliged to anchor at a considerable distance from the shore. Moreover, a dangerous surf is raised in stormy weather which renders landing difficult. At Kyrenia there is a little harbour fit only for small craft, and unprotected in northerly winds; and in days gone by there were harbours at Salamis, at Papho, and Famagusta.

The restoration of the last would greatly increase the strategic value as well as the commercial importance of Cyprus, but so far nothing has been done.

The rivers only flow after heavy rain or the melting of the snow in the hills. There are no lakes of any importance save that of Paralimni near Famagusta, which is noteworthy chiefly on account of the fact that whereas it becomes entirely dry in summer, it abounds in fish during the winter, a phenomenon which has never been explained, but which certainly cannot be called in question. The chief towns are Nicosia (the capital), Larnaca, and Limassol. Famagusta is a ruin; Papho, a site; Kyrenia and Morfu, villages on the northern coast. Until 1885 the topography of Cyprus was by no means accurately known, a state of things now put an end to by the issue of the great map of the trigonometrical survey of the island. This map, which was published in 1885, has been engraved by Messrs Stanford on a scale of one inch to the statute mile.

A census taken by order of government in 1881 showed the population to be 186,000, of whom 138,000 profess the Orthodox or Greek religion, and 48,500 the Mohammedan. Dividing the population according to language, 140,000 speak as their mother-tongue a form of the Romic or modern Greek, and 46,000 the Turkish. The Cypriot Greek dialect is a poor as well as a corrupt idiom, neither expressive nor harmonious. The language of the Cypriot Moslems, on the contrary, is remarkably pure, and is said to be the best Turkish spoken out of Stamboul.

History.—Cyprus was colonised at a very early period by the Phœnicians and subsequently by the Greeks, who gave to the island the name *Kypros*, and substituted the worship of Aphrodite (the Cyprian goddess, 'Paphian Venus'), to whom Cyprus was considered sacred, for that of the Phœnician Ashtaroth or Astarte. The ancient Cypriote syllabary was derived, according to Sayce, from the writing of the Hittites (q.v.). Early in the 6th century B.C. Cyprus was conquered by the Egyptian king Amasis; and a little later by Cambyses, who annexed it to Persia, 525 B.C. After the battle of Issus, Cyprus became a part of the Macedonian empire, but on the death of Alexander it passed into the possession of the Egyptian Ptolemy. In 58 B.C. Cyprus became a Roman province, and was administered by Cato the Younger and Cicero. The Cypriotes were one of the first Gentile peoples to embrace Christianity, and Cyprus was visited not only by St Paul but by many saints of the early church. At the division of the empire Cyprus naturally passed into the hands of the Eastern or Byzantine emperors, to whom it continued subject for over seven hundred years. In consequence of the supposed discovery by a shepherd of the body of St Matthew and part of his gospel near Salamis, in the 4th century, Cyprus was constituted by the empire a separate autonomous church, and to the archbishop was accorded the privilege, enjoyed only by the emperor himself, of signing his name in red ink, a privilege which has been uninterruptedly exercised to the present day. In 646 Cyprus was taken by the Saracens, under Othman, and again in 802 by Haroun al Rashid; but on each occasion it remained but a very short period under the sway of the Moslem. In 1195 Richard I., on his way to Syria for the third crusade, took the island from Isaac Comnenus, the representative or duke of the eastern emperor, and gave it to Guy de Lusignan, king of Jerusalem, in whose family the sovereignty of the island remained until 1487, when it passed under the dominion of the republic of Venice. In 1570 the Turks under Selim II. invaded Cyprus, and after long sieges and terrible massacres at

Famagusta and Nicosia, took possession of the country and ruled it for three hundred years. On the 10th July 1878 Cyprus was occupied by the British, under the provision of the celebrated Turkish Convention, by the terms of which the island is to be occupied by Great Britain until Batoum, Kars, and Erzeroum are restored to Turkey by Russia, England paying £92,440 a year to the Porte as quit rent. By a subsequent arrangement this 'tribute' is paid by Cyprus to England, and England pays one-half to France, or rather to the French bondholders of the 1854 Turkish Loan. The surplus revenue of Cyprus has never reached £92,000, and the deficit is made up by an annual grant by parliament. In 1880 the administration of Cyprus was transferred from the Foreign to the Colonial Office, and in 1882 a constitution, with an elected council, &c., was granted to Cyprus by Lord Kimberley.

Although under the convention the English maintain the Mohammedan religious tribunals, an admirable judicial system has lately been introduced, and English barrister-judges preside over courts which are highly appreciated by the people. The fiscal system, however, is well-nigh unreformed, and is most unsatisfactory, as is the system of land tenures. The Eastern Telegraph Company have stations throughout the island; rate to England, 1s. 3d. per word. Postal communication with England is very slow and unsatisfactory; within the island it is efficient. The police, 215 horse and 460 foot, under English officers, is an admirable force. Half a regiment of English infantry is quartered at Polimedia camp, 4 miles north of Limassol. There is no artillery in the island. The Cypriotes are peaceable, orderly, and easily ruled. Englishmen, almost exclusively officials, are popular. Few immigrants of any nation have been attracted to the country.

Cyprus produces wheat, barley, cotton, silk, flax, tobacco, carobs, mallder, wool, gypsum, oranges, pomegranates, sponges, gum-mastic, and immense quantities of wine. Carobs, or locust beans, are perhaps the most important export; the value in 1886 being £75,000; and in 1887, £103,000. Next in importance comes wine, of which 3,500,000 gallons, worth, say, £200,000, was produced in 1887 (as well as 200,000 gallons of spirits), and £66,000 exported; next cotton, about £28,000. The export of wheat fell off from £33,000 in 1886 to only £11,000 in 1887, though the amount grown in the country was in the latter year of the value of over £200,000. Barley is grown in very large quantities for home consumption, both as grain for horses and cattle, and as spring fodder in a green state in place of grass, of which none grows in the island. The export of mallder has entirely ceased since the adoption of aniline dyes. Wool and silk (cocoons) are each exported to the extent of about £80,000 a year, but a good deal of both is spun and woven in the country. The total value of all exports was in 1886 £284,000; in 1887, £312,000; but only about £80,000 worth of produce, or 19 per cent. of the whole, was shipped to Great Britain in consequence of the want of good communication between England and Cyprus.

Cyprus was once celebrated for its copper-mines, which were worked by the Phœnicians and Romans; indeed the word copper is derived from the name of the island. At the present day a concession granted to Messrs Knowles and Foster to mine copper at Limni, in the extreme west of Cyprus, is being worked by a company. Gypsum or plaster of Paris is manufactured at Larnaca in large quantities and exported chiefly to Alexandria. Salt was produced, under the Turks, to the value of £40,000 a year, by evaporation at the salines, near Larnaca, whence that town is sometimes called Salinas. At present, owing to prohibitive duties in the neighbouring countries, no salt is exported and only a very small amount for island consumption

is made by the British authorities. Cyprus imports (to the value in 1887 of £356,000) wheat, barley, olive-oil, sugar, textile fabrics, iron and copper goods, rice, dried fish, coal, timber, cotton-yarn and piece-goods, tobacco, petroleum, and goats.

The revenue in 1887 amounted to £187,000, of which about £30,000 was produced by customs, and £25,000 by excise, while of the remainder, some £30,000 was derived from land-tax, and over £80,000 from the tithe on produce, an oppressive, antiquated, and expensive form of taxation. The tithe on grapes was abolished in 1884. The expenditure in the island, curtailed from year to year since the occupation, amounted in 1887 to £110,000, leaving a surplus of about £77,000, which was sent to England as 'tribute.' The climate of Cyprus has been unduly vilified. When the English troops landed in the hot autumn of 1878 they were encamped in malarious situations and kept without appropriate shelter, food, or occupation, and it is true that most of them sickened and that many died. But for people who live regular lives and take reasonable precautions, the climate of Cyprus is not only healthy but very pleasant. The death-rate is low. Ophthalmia and intermittent fever of a mild type are the commonest forms of disease. Throat, chest, and lung complaints are exceedingly rare, but leprosy is not uncommon. The people are healthy and well grown; the men, as a rule, handsome, the women rarely so.

The *flora* and *fauna* are with few exceptions the same as those of the neighbouring coasts of Syria and Asia Minor. Among wild animals the mouflon or Cyprus sheep is the most interesting, but is becoming very scarce. Mules of peculiar excellence are bred in Cyprus and command large prices. Goats are amongst the pests of the island. The forests (for which Cyprus was once famous) have well-nigh disappeared, and the climate and fertility of the country have greatly suffered in consequence. Nothing is being done to re-afforest the island, and the flocks of goats prevent any natural growth of trees on the mountains, by biting off the tops of the young shoots as fast as they appear. A still greater scourge has commanded the attention of the authorities, and the locusts are now almost exterminated. The work of destruction has been thoroughly as well as economically performed (especially 1880-84), upon a system invented by a Cyprus gentleman, Mr Richard Mattei, C.M.G.

The English have done little in the way of road-making in Cyprus. Limassol was still in 1888 unconnected by road with Nicosia, the capital, a distance of about 55 miles. The old Turkish road from Nicosia to the sea-coast at Larnaca has been repaired and is now in excellent order, but it is still the only road from one district town in the island to another adapted for wheel traffic in all weathers. Wheeled conveyances are accordingly rare, and merchandise is carried on the backs of camels, mules, and donkeys. Travellers ride mules and ponies. See works on Cyprus published in 1879-80, by Cesnola, Lang, Hepworth Dixon, Sir S. Baker, Mrs Scott Stevenson; articles in *Blackwood* and *National Review*, March 1888; Blue-book, *Affairs and Finance of Cyprus*, September 1888. The best authority on the antiquities of Cyprus is vol. iii. of the great work, *L'Art et l'Antiquité en Orient*, by Perrot and Chipiez (Eng. trans. 1885).

Cyrenaica, the name of the district in northern Africa whose capital was Cyrene (q.v.). In its widest limits it stretched from the borders of Carthage to the Chersonesus Magna or northern headland of the Gulf of Platea (Gulf of Bomba). The productions of Cyrenaica mentioned by ancient writers are corn, oil, wine, honey, fruits of all kinds, cucumbers, truffles, cabbage; flowers yielding the richest perfumes; a rare plant called

silphium (still abundant), from which was obtained a famous medicinal gum-resin; and its horses. The first settlements in Cyrenaica were made by a Spartan colony in 631 B.C. The earliest cities were Teuchira and Hesperis, then Barca, a colony from Cyrene; and these, with Cyrene itself, and its port Apollonia, formed the original Libyan *Pentapolis*; subsequently, Hesperis became Berenice; Teuchira, Arsinoë; while Barca was eclipsed by its port, which became a city with the name of Ptolemais. Cyrenaica at length became Roman, and under Constantine was constituted into a province as Libya Superior. In the 7th century it was overrun by the Arabs, and now nearly corresponds with Barca (q.v.).

Cyrené, the capital of Cyrenaica (q.v.), founded in 631 B.C., by a colony of Spartans under Battus, whose dynasty ruled for nearly two centuries, and was replaced by a republic, which was far from prosperous, until the Roman rule at length gave it rest from party conflicts. During its prosperity Cyrene carried on a great commerce with Greece and Egypt, and to a less extent with Carthage. Its extensive ruins still attest its former magnificence. It is repeatedly mentioned in the New Testament. Here were born the philosophers Aristippus (q.v., founder of the *Cyrenaic School*), Anniceris, and Carneades, the poet Callimachus, the astronomer Eratosthenes, and the Christian rhetorician and bishop, Synesius.

Cyrenius, a Grecised form of Publius Sulpicius Quirinus, named in Luke ii. as governor of Syria. He received his appointment as governor in 6 A.D.; but the difficulty in harmonising this with Luke is got over by admitting that he had been governor also at an earlier date—according to Zumpt, from 4 B.C. to 1 B.C.

Cyril and Methodius, apostles of the Slavs, were brothers, and natives of Thessalonica. Cyril was the name adopted as a monk by Constantine, born in 827. He had been a disciple of Photius, and for his learning was surnamed 'the philosopher.' The Khasars, a Tartar people who inhabited the country from the north-east of the Black Sea to the lower Volga, having about the year 860 asked the Emperor Michael III. to send them Christian missionaries, Cyril was sent in answer to their appeal, and made many converts. The Bulgarians of Thrace and Mœsia were evangelised by Methodius, who baptised their king Bogoris in 861. At the request of Ratislav, Duke of Moravia, the brothers then turned to the countries on the March and Danube. They prepared a Slav translation of the Scriptures and chief liturgical books (which became the foundation of the literature of the Slavs), and by their services in the mother-tongue won the hearts of the people from the Roman missionaries. The two brothers were summoned to Rome to explain their conduct, and Cyril died there in 869. Methodius, who in the same year was consecrated at Rome Bishop of the Moravians, completed the evangelisation of the Slavs. Called to Rome a second time in 879 to justify his celebration of the mass in the native tongue, he succeeded in gaining the approval of Pope John VIII., returned to his diocese in 880, and (according to the most probable account) died at Hradisch on the March, 6th April 885. Bohemia and Moravia celebrated the millenary festival of their two apostles on the 5th July 1863. Both brothers are recognised as saints by the Roman Catholic Church, after having been condemned as Arians by several popes (including Gregory VII.). Their festival falls in the Roman Catholic Church on the 9th of March, in the Greek Church on the 11th of May. The Cyrillic alphabet, modified out of the Greek by Cyril, superseded the

more ancient Slavonic alphabet over a wide area. The history of Cyril and Methodius is still very obscure. The sources are collected by Schafarik in vol. ii. of his *Slavische Alterthümer* (Ger. trans. 2d ed. 1863), and more completely by Ginzl in his *Geschichte der Slavenapostel Cyril und Method* (Leitmeritz, 1837). See also Dümmler and Miklosich, *Die Legende vom Heiligen Cyril* (Vienna, 1870).

Cyril of Alexandria, St, one of the Fathers of the church, was born at Alexandria, and brought up under the care of his uncle Theophilus, whom, after some years spent as a monk in the Nitrian desert, he succeeded as patriarch of Alexandria in 412. Cyril forthwith closed the churches of the Novatians, and in 415 expelled the Jews from the city. With the shameful murder of Hypatia (q.v.) he was at least indirectly connected. The latter part of his life was spent in his relentless persecution of Nestorius (q.v.), against whom, in the name of a synod held at Alexandria in 430, he hurled twelve anathemas for his refusal to apply to the Virgin Mary the epithet *Theotokos* ('Mother of God'). The oecumenical council of Ephesus in 431 condemned Nestorius, with his doctrine of the two natures in Christ. After this, John of Antioch, with his adherents (numbering from 30 to 40 bishops), who had arrived at Ephesus too late to take part in the discussion, constituted a synod of their own, which condemned Cyril. The emperor confirmed both of these depositions, but Cyril, notwithstanding, kept his patriarchate till his death in 444. On hearing of his death, Theodoret wrote, 'Envy is dead, and heresy is buried with her.' Among the extant works of Cyril are a defence of Christianity, in 10 books, written against the Emperor Julian in 433; a series of homilies and dogmatic treatises on the Trinity, the Incarnation, and on the Worship of God in spirit and in truth (17 books, written against the Anthropomorphites). The best edition of his works is that of Aubert (7 vols. Paris, 1638). See Neander's *Church History*, Newman's *Historical Sketches* (vol. ii.), Kingsley's *Hypatia*, Hefele's *History of the Councils* (vol. ii.), and Kopallik, *Cyril von Alexandria* (Mainz, 1881).

Cyril of Jerusalem, St, was born probably about 315, but his descent and birthplace are unknown. About 334 he was ordained a deacon, and about 345 a presbyter. During the Arian controversies he endeavoured to maintain a neutral attitude, and in 351 was ordained Bishop of Jerusalem by Acacius, Bishop of Caesarea, who was an Arian. Cyril having repeatedly disregarded citations by Acacius, his metropolitan, was deposed by him in 358, and by a synod at Constantinople in 360; but on the accession of Julian in 361 he returned to his flock, which he ruled in peace till 367, when, by order of Valens, he was again expelled. He returned to Jerusalem on the death of Valens in 378, took part in the second oecumenical council at Constantinople, and died on the 18th (according to other accounts, on the 11th or 20th) March 386. The genuine writings of Cyril are his *Katēchēseis* (or instructions to catechumens), eighteen of which are addressed to candidates for baptism, and five to the newly baptised. They are not in the form of question and answer, but are connected lectures, written in a style of great simplicity and clearness, and making constant reference to Scripture. The articles of the creed (called by Cyril *Pistis*, or the 'Faith') on which the teaching is based can be gathered with tolerable certainty from the last thirteen of the first series of the *Katēchēseis*, and are distinguished from those of the Nicene Creed by the avoidance of its distinctive word *Homousios* ('of the same substance'). The best editions are

by Touthée (Paris, 1720; new ed. 2 vols. 1844) and by Reischl and Rupp (2 vols. 1845-60). There is an English translation in the *Oxford Library of the Fathers* (vol. iii. 1838). See also works on Cyril by Plitt (1855), Gonnet (1876), and Marquadt (1882).

CYRUS THE GREAT (*Kurus*, perhaps from *kur*, 'a mountain'), the founder of the Persian empire. He was the fourth in a line of kings of Anzan or Susiana (called by the Hebrews *Elam*) who formed a branch of the royal dynasty of the Achæmenides (q.v.). According to Herodotus, Cyrus was the son of Mandane, daughter of Astyages, king of Media, and the Persian Cambyses. Moved by superstitious fears, Astyages attempted to destroy him in his infancy, but the child was saved by a herdsman, who brought him up as his own son. Being recognised in his boyhood by Astyages, he was sent to his parents in Persia. Cyrus in course of time rose against Astyages and conquered him. This narrative and the greatly varying accounts of Xenophon, Ctesias, Nicolaus of Damascus, Diodorus, and Trogus Pompeius, formerly regarded as the authorities for the life of Cyrus, have been superseded by the evidence of recently discovered monuments. A new light has been thrown on his history by the discovery of his own cuneiform records on a clay tablet and cylinder recently brought from Babylon to England. Cyrus was the son of Cambyses I., grandson of Cyrus I., and great-grandson of Teispes, conqueror of Elam, who was also the great-grandfather of Hystaspes, the father of Darius (q.v.). From the tablet-inscription we learn that in the sixth year of Nabonidus, king of Babylon (549 B.C.), Cyrus, 'king of Elam,' conquered Astyages, king of Media, made him a prisoner, and took his capital, Ecbatana. By the year 546 he had become 'king of Persia.' Year after year was idly spent by Nabonidus at Tema, a suburb of Babylon, while his son (doubtless Belshazzar) was with his army in Akkad (Northern Babylonia). In 538 Cyrus, favoured by a revolt of the tribes on 'the Lower Sea,' or Persian Gulf, advanced on Babylon from the south-east, and, after giving battle to the army of Akkad, took Sippara (Sepharvaim) and Babylon itself 'without fighting.' The account of the siege of Babylon by Cyrus recorded by Herodotus must therefore be erroneous. The Greek historian seems to have transferred to the reign of Cyrus events which took place in the reign of Darius. On the eighth day after Cyrus entered Babylon in person, he appointed Gobryas its governor, and that very day Nabonidus died. Nabonidus in his distress had brought the images of many local gods to Babylon, so as to protect it from the invader; and the cylinder-inscription shows very clearly that Cyrus was a polytheist and an idolater, for he there says, 'the gods dwelling within them left their shrines in anger when [Nabonidus] brought them to Babylon,' and, after telling how he had restored them all to their sanctuaries, prays them to intercede before Nebo and 'Merodach my lord,' for himself and Cambyses his son. Cyrus at once began a policy of religious conciliation. The nations who had been carried into captivity in Babylon along with the Jews were restored to their native countries, and allowed to take their gods with them. The empire of Lydia had fallen before the army of Cyrus two years before (in 540), and after the conquest of Babylonia he was master of all Asia from the Mediterranean to the Hindu Kush. The conqueror's hold over Asia Minor and Syria was much strengthened by his friendly relations with the Phœnicians and also with the Jews, who received the news of his triumphs with enthusiastic sympathy as the confirmation of the prophetic aspirations for their national deliverance. In the

Old Testament he is called the Shepherd and the Anointed of Jehovah, because in 538 he gave the Jews who were living in captivity in Babylon permission to return; yet it is expressly said of him: 'For Jacob My servant's sake, and Israel My chosen . . . I (Jehovah) have surnamed (or *titled*) thee, though thou hast not known Me . . . I will gird thee, though thou hast not known Me' (Isa. xlv. 4, 5). The favour which he showed to the Jewish people awoke the hope that he might be won over to faith in Jehovah as the one true God; but doubtless he was less moved by religious than by political motives to allow the Jews to return to their own land. After the great king had extended the boundaries of his empire from the Arabian desert and the Persian Gulf in the south, to the Black Sea, the Caucasus, and the Caspian in the north, he died in 529—according to Herodotus and Diodorus, during an unsuccessful struggle with Tomyris, queen of the Massagetae, on the Jaxartes; according to Ctesias, of a wound which he had received while conquering the Derbicci on the upper Oxus. The empire of Cyrus was organised under satraps and minor governors, after the manner of the second empire of Assyria. Three years before his death, Cyrus made his son and successor Cambyses 'king of Babylon.' His own title was 'king of the world.' The chief seat of his court was Ecbatana; during the spring months it was held at his old capital, Susa, or Shushan, in Elam. Cyrus takes a high rank among Asiatic conquerors; he was a wise and considerate ruler, whose aim was to soften by his clemency the despotism which he was continually extending by the sword. But he did little to consolidate the empire which he founded, contenting himself with a declaration of allegiance, and leaving the government nearly everywhere in the hands of native rulers. He brought the greater part of the Old World (Egypt excepted) under his sway, but left the organisation of his conquests to his successors. The *Cyropædia* of Xenophon is obviously an historical romance. See Professor Sayce's *Introduction to Ezra, Nehemiah, and Esther* (2d ed. Lond. 1887); also his *Fresh Light from the Ancient Monuments* (1883).

CYRUS THE YOUNGER, the second of the sons of Darius Nothus (or Ochus) and Parysatis, was born in 424 B.C. He conspired against his brother Artaxerxes Mnemon, who had succeeded to the throne (404 B.C.). The plot, however, being discovered, he was at first sentenced to death, but afterwards pardoned, and even restored to his dignity as satrap of Asia Minor. Here he employed himself in making arrangements for war against his brother, although he concealed his purposes to the very last. In the spring of 401 B.C. he left Sardis at the head of 100,000 Asiatics and 13,000 Greek mercenaries, under pretence of chastising the robbers of Pisidia. Artaxerxes being warned of Cyrus's perfidy, made preparations to oppose him, and the two armies encountered each other in the plains of Cunaxa, 500 stadia from Babylon. Cyrus was defeated and slain, although the Greeks fought with the greatest courage, and even routed that portion of Artaxerxes' troops immediately opposed to them. The fortunes of the Greeks, on their retreat through the highlands of Armenia, in severe winter-weather, are recorded by Xenophon in his *Anabasis* (q.v.).

Cyst (*kystis*, 'a bladder'), a word sometimes used in the original sense as applied to hollow organs with thin walls, as the urinary bladder and gall-bladder; but commonly reserved for the designation of pathological structures or new formations within the body having the bladder form. Cysts may arise in two different ways: (1) either

by the accumulation of products within cavities normally present, or (2) by the independent formation of a cavity. Of the first, wens, collections of secretion in a sebaceous gland of the skin, are the commonest example; instances of the second are cystic tumours of the Ovary (q.v.) and the sacs developed in connection with certain parasites ('bladder-worms'; see HYDATIDS, ENTOZOA). The structure of their walls is still more variable than their mode of origin; sometimes they are thin and transparent, sometimes dense and fibrous. They are either simple or compound, unilocular or multilocular; they are sometimes small, numerous, and separate; in other cases they grow to an enormous size, and are very complex. Some cysts are present at birth, and remain through life almost unchanged; some increase rapidly in size, and form large and dangerous tumours. For Cystic Worms, *Cysticercus*, see BLADDER-WORM, CESTOIDS, TAPEWORM.

Cystin, or CYSTIC OXIDE, forms a rare variety of urinary Calculus (q.v.). Its chemical composition is $C_2H_7NSO_2$, and it forms a whitish or dirty yellow deposit consisting of six-sided crystalline tablets. It is soluble in ammonia, and is thereby distinguished from the similar crystals of uric acid.

Cystitis, inflammation of the Bladder (q.v.).

Cystoidea (Gr. *cystis*, 'a bladder'), a group of fossil echinoderms, so called from their spherical or bladder-like form. The spherical body was inclosed by calcareous plates, and resembled that of the crinoids in general form. It was borne on a short stalk, or was sessile. See CRINOIDEA.

Cythera. See CERIGO.

Cytisus, a large genus of Leguminosæ, sub-order Papilionaceæ, small trees or shrubs, with ternate leaves, and yellow, white, or purple flowers, natives chiefly of the warmer temperate parts of the Old World, but frequently introduced on account of the beauty of their flowers (see LABURNUM). In its widest sense the genus may include the common Broom (q.v.).

Cyzicus, the ancient name of a peninsula of Asia Minor, projecting into the Sea of Marmora, which lies immediately to the SE. of the island of Marmora, and is about 9 miles in length. It was at one time an island. In early times Cyzicus was a Milesian colony, and the city of Cyzicus, which was not finally ruined till its conquest by the Arabs in 673, is described by Strabo as one of the first cities in Asia, alike for extent and splendour.

Czar, more properly *Tsar*, *Tzar*, or *Zar*, the title of the emperors of Russia. The word occurs early in Old Slavonic, equivalent to king or *kaiser*, and is connected with the Latin *Cæsar*, continued in the Roman empire as a title of honour long after the imperial house itself had become extinct. In the Slavonic Bible the word *basileus* is rendered by *czar*; *Cæsar* (*kaisar*) by *Cesar*. In the Russian chronicles also the Byzantine emperors are styled *czars*, as are also the khans of the Mongols who ruled over Russia. The title of the Russian princes was *kniaz* ('prince') and *veliki kniaz* ('great prince'); and the princes of Moscow took the title of *czar* as rulers of the Mongolians. As individual sub-khans made themselves independent of the kingdom of the Golden Horde, they also assumed the title of *czar*; thus, there were *czars* of Siberia, of Kasan, and of Astrakhan. The conquest of the Golden Horde by the khan of the Crimea in 1480 made the grand-princes of Moscow completely independent; and upon them devolved the absolute power which the *czars* had exercised over all Russia. Ivan IV. the Terrible first caused him-

self to be crowned *czar* in 1547; from that time the title of *czar* became the chief title of the Muscovite rulers, and became practically the equivalent of emperor. The wife of the *czar* was named *tzaritzá* (*czarina*); the sons, *tzarevitch*; the daughters, *tzarevna*; but after the death of Alexei—Peter I.'s son—these titles were abolished, and the imperial princes were called grand-dukes, and the imperial princesses grand-duchesses. In 1799 the Emperor Paul I. introduced the title of *cesarevitch* (not *czarevitch*) for his second son, the Grand-duke Constantine. The heir-apparent and his wife are still called *cesarevitch* and *cesarevna*. Among the Russian people themselves, the emperor is more frequently called *Gossudar* (*Hospodar*, 'Lord') than *czar*. The term White *Czar*, *bělyj zar*, comes down from Mongol times, and is merely equivalent to an independent, non-tribute-paying *czar*. See RUSSIA.

Czardasch, or CSÁRDÁS, a Hungarian national dance, consisting of two sections—a slow movement called a *lassu* or *lassan*, and a quickstep, the *friss* or *friska*. Both are always in $\frac{3}{4}$ or $\frac{2}{4}$ time, and in the same key. Examples on an extended scale occur in Liszt's 'Rhapsodies Hongroises.'

Czartoryski, ADAM GEORGE, son of Prince Adam Czartoryski (1734–1823), was born at Warsaw, 14th January 1770. Educated at Edinburgh and London, he returned to Poland, and took part against Russia in the war of 1794. Sent to St Petersburg as a hostage, he gained the friendship of the Grand-duke Alexander and the confidence of the Emperor Paul, who made him ambassador to Sardinia. When Alexander ascended the throne, he appointed Czartoryski assistant to the Minister of Foreign Affairs; and he took an active part in official life until after the peace of Tilsit. As curator of the university of Wilna (1803) he exerted all his influence to keep alive a spirit of nationality; and when some of the students were sent to Siberia on a charge of sedition, Czartoryski resigned his office. His successor reported to the emperor that the amalgamation of Russia and Lithuania had been delayed a century by Czartoryski. Russian favours could not deaden or even dull Czartoryski's pure patriotism. Into the revolution of 1830 he threw himself with all his heart. He was elected president of a provisional government, and in this capacity summoned a national diet, which in January 1831 declared the Polish throne vacant, and elected Czartoryski head of the national government. He immediately devoted half of his large estates to the public service, and adopted energetic measures to meet the power of Russia. In August he resigned his post, but continued to fight as a common soldier. After the suppression of the rising (see POLAND), Czartoryski—specially excluded from the general amnesty, and his estates in Poland confiscated—escaped to Paris, where he afterwards resided, the liberal friend of his poor expatriated countrymen, and the centre of their hope of a revived nationality. In 1848 he liberated all his serfs in Galicia, and during the Crimean war he ineffectually endeavoured to induce the allies to identify the cause of Poland with that of Turkey. He refused the amnesty offered to him by Alexander II., and died 15th July 1861. See his Memoirs, translated by Gielgud (1888).

Czaslau (Bohemian *Cáslav*), a town of Bohemia, 40 miles ESE. of Prague by rail, with manufactures of beet-sugar and alcohol. Its church, in which the Hussite leader Ziska was buried, is surmounted by the highest steeple in Bohemia (290 feet). The place was the scene of

an important victory gained over the Austrians by Frederick the Great, 17th May 1742. Pop. 6878.

Czechs (also spelt *Tzechs*, *Tschechs*, *Cesks*, *Chesians*, &c.), the most westerly branch of the great Slavic family of nations. In the latter half of the 5th century A.D. the Czechs migrated from their lands in Carpathia, on the upper Vistula, to the country now known as Bohemia. Other Slavic tribes came too; but in the course of time the Czechs gained such an ascendancy that, in the 9th century, their name was commonly applied to the whole Slavic population of Bohemia (q.v.). Here, in Moravia, and in other parts of Austria, the Czechs now number in all some 7,000,000.

Czegled, a market-town of Hungary, 47 miles SE. of Pesth by rail. The inhabitants (1880), 24,872 in number, are employed principally in agricultural pursuits, the district around yielding much grain and red wine.

Czenstochau, or CZENSTOCHOWA, a town of Poland, 148 miles SW. of Warsaw by rail. A Catholic monastery, founded here about 1382, is visited yearly by fifty to sixty thousand pilgrims, as possessing the famous 'Black Virgin,' a murky painting of Byzantine origin, but ascribed by legend to St Luke himself. In 1655 Czenstochau was the only place in Poland which offered resistance to Charles Gustavus of Sweden, when 70 monks and 150 soldiers for 38 days held out against 10,000 men. The inhabitants, 15,500 in number, carry on a considerable trade in sacred pictures and rosaries.

Czermak, JOHANN NEPOMUK, physiologist, was born, 17th June 1828, in Prague, studied at Vienna, Breslau, and Würzburg, was professor successively at Cracow, Pesth, Jena, and Leipzig, and died 16th September 1873. He was the founder of laryngoscopy. His principal work is *Der Kehlkopfspiegel* (2d ed. 1863), and his collected works were published in 1879.

Czerno'witz, the capital of the Austrian province of Bukowina, stands 720 feet above sea-level, near the right bank of the Pruth, 165 miles SE. of Lemberg by rail. Among its buildings are the palace of a Greek archbishop (1875); his cathedral (1864), on the model of St Isaac's at St

Petersburg; the Armenian church (1875); the synagogue (1877); and the 'Austria Monument' (1875). The university, founded in 1875, has 36 instructors and some 225 students. The manufactures and trade are steadily developing. Pop. (1869) 33,884; (1880) 45,600, of whom 14,449 were Jews.

Czerny George (Turkish *Karadjordje*)—i.e. Black George, the leader of the Servians in their struggles for independence, was born of poor parents, 21st December 1766, near Kragujevatch. He took part in a rising against the Turks in 1787, and was subsequently a cattle-dealer. In August 1801, a band of janizaries broke into his dwelling, and plundered it. Czerny fled, vowing vengeance. He soon collected a band of malcontents, and commenced a sort of guerilla war. Gradually his numbers increased, and in 1804 he captured the fortress of Schabaz. Subsequently, he invested Belgrade, and in the beginning of 1806 routed the Turks at the rivers Drina and Morawa. Assisted secretly by Russia, he captured Belgrade in December 1806. After the treaty of Slobosja (8th July 1808), he was elected governor by the people, and recognised as Prince of Servia by the sultan. The French invasion of Russia in 1812 compelled the latter country to let Servia shift for itself. Hostilities recommenced; the Turks were successful, and Czerny had to flee to Austria, where he lived for some time. Meanwhile, the freedom of Servia had again been secured through the leadership of Milosch Obrenowitch; and when, in July 1817, Czerny returned, he was murdered at the instigation of Prince Milosch.

Czerny, KARL, pianoforte teacher and composer, born at Vienna in 1791, was the pupil and friend of Beethoven, and also gained much from Clementi and Hummel. Besieged by pupils, he would teach only those who showed especial talent; among these were Liszt, Thalberg, and Döhler. Living in great retirement, he devoted much of his time to composition; a mass of MS. is preserved in the archives of Vienna, while his published works number over 900, of which his *Theoretical and Practical School* is the best known, and probably also the most valuable. He died 15th July 1857.

D

is the fourth letter in our own alphabet, as well as in the Phœnician, Hebrew, Greek, and Latin, from which last it was immediately derived. The original symbol in the Egyptian hieroglyphs was the picture of a hand. When

taken over by the Phœnicians, this sign was called *daleth*, 'the door,' from a fancied resemblance to the curtained aperture of a tent, rather than to the wooden quadrangular door of a house. This resemblance may be traced in the Greek letter Δ, whose name *delta* was derived from the Semitic *daleth*. In Phœnician and the oldest Greek, the letter had a short tail, Α, but as this form differed very little from that of Β, and hardly at all from that of Ρ, the three letters were differentiated, Β acquiring a second loop, Ρ a tail, while Δ lost the downward prolongation of the stem.

In cursive Greek the letter was rounded, and acquired the form δ, which is due to the ligature connecting it with the following letter. These changes are shown in the table given in Vol. I., page 187, which also explains the singular process whereby, in the minuscule form δ, the loop of Δ has been transferred from the right of the stem to the left. In the Aramean alphabets the loop opened out, as is seen in the Hebrew ד.

The sound of D is the soft dental mute. It has, like *t*, an affinity for *n*, and is often brought in as a sort of shadow to facilitate the utterance of this letter. It is intrusive in such words as *sound*, *compound*, *lend*, *riband*, *gender*, *thunder*, *kindred*. Sometimes it disappears, as in the case of *cruel* from *crufelis*, or *winnow* from *windewe*. It is often assimilated to the following consonant, especially in compounds derived from the Latin, as in the words *accept*, *attain*, *allocution*, *appear*, *affirm*, *arrogant*, *gossip*. It is sometimes replaced by *t*, *r*, or *b*, as in the words *lacrima*, *Ulysses*, *lingua*, *arbiter*, *meridies*, *bellum*, *bonus*, *bis*. By Grimm's Law a primitive *d* becomes *t* in English, and *z* in German: as in the words *decem*, *ten*, *zehn*; or *duo*, *two*, *zwei*. A primitive *dh* becomes *θ* in Greek, *th* in German, *f* in Latin, and *d* in English; as the words *thip*, *thier*, *fera*, and *deer*. *Di* followed by a vowel sometimes becomes *j*, as in *journal* from *diurnal*.

D, the Roman numeral for 500, arose out of IO, the half of CIO, which was the old way of writing Φ, the primitive sign for 1000, which was afterwards written M.

D, in Music, is the second note in the natural scale. See MUSIC, SCALE.

Dab (*Pleuronectes limanda*), a species of Flounder (q.v.), common on European coasts, but not occurring in the Mediterranean. It is distinguishable from plaice and flounder by its light-brown, or ashen-gray colour, with small irregular dark spots, by the roughness of its small, close-set scales, and by its more arched lateral line. Its length is from 8 to 16 inches. It is common all round Britain, and in the Firth of Forth is known as the Salt-water Fluke. Its flavour excels that of flounder. A rather larger species, of even more

northern distribution, is the Lemon or Smooth Dab (*P. microcephalus*). It may be distinguished from

Dab (*Pleuronectes limanda*).

the common dab by the fact that the first ray of the anal fin is not spiny. The brownish colour is sometimes prettily mottled.

Dabchick. See GREBE.

Da Capo (Ital., 'from the beginning'), a term in Music, frequently placed at the end of a part or movement, indicating that the performer must return to the beginning of the movement, or (*dal Segno*) to some other part of it marked with the sign ♪, and finish where the word *fine* is placed. The words are generally abbreviated thus, D.C., sometimes *D. C. al fine*.

Dacca, a city of Bengal Proper, 150 miles NE. of Calcutta, on the north bank of the Buriganga, occupies an area of 8 sq. m., and consists of a dull esplanade and one long street meeting at right angles, with a complementary network of narrow, crooked lanes. Its position commands the principal waterways of the delta, and it thus enjoys singular facilities in the way of inland navigation. On this account it was chosen, about 1610, as the seat of the Mohammedan government of Bengal, which rank it retained, except during an interval of twenty years, until 1704. The suburbs extended 15 miles northward, where mosques and brick buildings are still found buried in thick jungle. In the 18th century it became widely celebrated for the delicate texture of its muslins, and in connection with this manufacture the French and the Dutch, as well as the English, had extensive establishments in the place. After 1817, however, the annual value of the trade declined, under the competition of Manchester piece-goods, and the aspect of the city changed with the disastrous decay of its staple industry. Its busy marts were deserted; in many quarters the streets, with their desolate, abandoned houses, were overgrown with jungle; and the population fell from 200,000 in 1800 to 69,212 in 1872. Since then the fortunes of Dacca have somewhat brightened; the general development of trade throughout the presidency has brought back a share of its former prosperity, and the opening of the Dacca and Maimansingh State Railway in 1886 has notably increased the transit trade. A small colony of muslin-weavers still survives, and other manufactures are coarse cotton cloth, embroidery, silver-work, shell-carving, and pottery. Besides the Dacca College (1835), with about 300 students, there are many good schools, and a fine

hospital; in 1878 a system of water-works was opened, and the sanitary condition has since improved. Pop. (1881) 79,076.—**DACCA DISTRICT** has an area of 2797 sq. m., and consists of a level plain, intersected by a network of rivers and artificial watercourses. Two-thirds of the district is under cultivation; food-crops, oil-seeds, jute, cotton, safflower, and sugar-cane are grown. Trade is carried on chiefly by water, and the rivers are crowded at all seasons with steamers and native craft; the adventurous boatmen of the district have a name throughout Bengal. Floods, blight, or drought never seriously affect the district, but earthquakes are of common occurrence. Outside Dacca city sanitation is unthought of; fevers, dysentery, and goitre are among the endemic diseases, and epidemics of cholera and smallpox are not infrequent. Pop. (1872) 1,852,993; (1881) 2,116,350, of whom 59 per cent. were Mohammedans.

Dace, **DARE**, or **DART** (*Leuciscus vulgaris*), a fresh-water fish in the carp family Cyprinidae (q.v.), and of the same genus as the roach, chub, minnow, &c. It chiefly inhabits the deep and clear water of quiet streams. It is found in Italy, France, Germany, &c., and in some of the rivers of England, but is very local. In form it is not unlike the roach, but rather more elongated; the mouth is rather larger, the scales smaller. The upper parts are dusky blue, becoming paler on the sides, and

Dace (*Leuciscus vulgaris*).

passing into white on the belly, the cheeks and gill-covers silvery white. It measures about 8 inches in length, and never exceeds a pound in weight. The dace is gregarious, and swims in shoals. It spawns in early summer. Its flesh is preferred to that of the roach, but is not highly esteemed. The dace is perhaps the liveliest and most active of the Cyprinidae, and affords the angler fair sport both with fly and bait.

Dachshund, a name adopted from the German, signifying 'badger-dog.' The dachshund has been common in Germany for many years, but was unknown in England until introduced by the late Prince Consort towards the middle of the 19th century; it then became very fashionable and popular, but is not now so common. The dachshund is a small dog, weighing about 20 lb., with short crooked fore-legs, and an extremely long body, its head rather resembling that of a miniature bloodhound. Its strong, large paws enable it to dig rapidly. Its colour should be black and tan, or brown. On the Continent the dachshund is extensively used for covert-shooting, but rarely so in Britain, as his headstrong disposition somewhat spoils his usefulness. The dachshund is closely akin to the old English *Turn-spit*, employed to drive a wheel by which roasting-spits were turned.

Dacia, the land of the ancient Daci or Getæ, including the country between the Danube, the Theiss, the Carpathians, and the Pruth. The Dacians were the most valiant of all the tribes of Thracian origin (see **THRACE**). In the reign of Augustus they began to molest the Roman allies, and indeed from this time there was almost continual fighting between the Romans and the Daci,

who actually, under their brave king, Decebalus, compelled their civilised enemies, in the reign of Domitian, to purchase peace by paying tribute. In 101 the Emperor Trajan crossed the Danube, and after five years' desperate fighting, conquered the whole country, and formed it into a Roman province. Roman colonists were sent into the country, great roads were opened up, and a bridge was built over the Danube—the ruins of which are still extant. Under Aurelian the Danube was made the boundary of the empire, and Dacia was resigned to the barbarians, its Roman colonies being transplanted to Mœsia.

Dacier, **ANDRÉ**, a French scholar, born of Protestant parents at Castres, in Upper Languedoc, 6th April 1651, studied at Saumur under Tanneguy Lefebvre; and in 1672 came to Paris, where in 1683 he married Anna (1654–1720), his old preceptor's daughter, and two years later was admitted with her to the Roman Catholic Church. Dacier subsequently became royal librarian, member of the Academy of Inscriptions and of the French Academy, and perpetual secretary of the latter. He died 18th September 1722. His works include a Delphin edition of Festus and Verrius Flaccus (1681), as well as indifferent translations of Horace, the *Poetics* of Aristotle, some of the Dialogues of Plato, Epictetus, and Plutarch's *Lives*. His wife's works include Delphin editions of Florus, Aurelius Victor, Eutropius, Dictys Cretensis, and Dares Phrygius; and translations of Anacreon, Sappho, some plays of Plautus and Aristophanes, Terence, the *Iliad* and the *Odyssey*. Her admiration of Homer was more unbounded than discriminating, and involved her in many controversies.

Dacoits, a name used for brigands herding in gangs in various parts of India, and living by *dacoity* or robbery with violence. According to the report of the general superintendent of the Thuggee and Dacoity Department in 1887, there were over 9000 men practising dacoity in India, which in some districts is carried on with great ferocity. In the Gwalior territory forty-six persons were killed by dacoits; and of the seventy-five villages in the Chanderi district, thirty-six had been dacoited since 1880. After the annexation, dacoity was very prevalent in Burma.

Da Costa, **ISAAC**, a Dutch poet, born at Amsterdam, the son of a Portuguese Jew, 14th January 1798. He studied at Leyden; and in 1822, a year after receiving the degree of doctor of philosophy, he embraced Christianity. His poems speedily gained him such reputation that, on the death in 1831 of Bilderdijk, whose warm friendship he had enjoyed, Da Costa succeeded him in the first place among the poets of Holland, which he held till his death, on 28th April 1860. His principal works are to be found in his *Poëzij* (2 vols. 1821–22), *Politieke Poëzy* (1854), and *Hesperiden* (1855). His *Battle of Nieupoort*, the last of his poems, is one of his masterpieces. Da Costa also made essays in the domain of history and theology, the most important of which, his *Israel and the Gentiles*, has been translated into English.

Dacotahs. See **SIOUX**, **AMERICAN INDIANS**.

Dacrydium, a genus of coniferous trees of the yew family, but more allied to Podocarpus. There are twelve species—Malayan, Tasmanian, and of New Zealand. *Dacrydium cupressinum* of New Zealand is best known in Britain, on account of the beauty of its pendulous foliage. *D. franklinii*, the so-called Huon Pine, and *D. taxifolium*, the Kakaterra tree, yield valuable timber.

Dactyl (Gr. *dactylos*, 'finger'), the name of a measure or 'foot' in Greek and Latin versifica-

tion, consisting of a long and two short syllables, as in the word *omnibús*. It was so called from its resemblance to the finger, which consists of three joints—one long and two short. The same name is sometimes applied to a trisyllabic measure in English verse, consisting of one accented syllable and two unaccented syllables, as in *déstiný* (see VERSE). Dactylic verse consists of dactyls and spondees, and includes both hexameter and pentameter verse.

Dactylogy, the art of communicating thoughts by the fingers. See DEAF AND DUMB.

Daddy-long-legs, or CRANE-FLY (*Tipula oleracea*), a familiar insect in the order Diptera, and a good type of its family Tipulidæ. The body, the legs, and the antennæ are very long. The latter have an arched curvature, and are longer in the males; the front of the head projects prominently; the posterior body, which is connected with

Daddy-long-legs (*Tipula oleracea*):

a, eggs; b, larva; c, pupa case as left by the insect sticking out of the earth; d, perfect insect.

the thorax by a very thin bridge, is broader in the females. The middle of the body is gray, with brown stripes, the abdomen reddish-brown, the legs brownish-yellow, and in part blackish, the wings brown, varying to red and white. This common European insect is towards an inch in length, is abundant from July to October in meadows and gardens, and is familiar to every one. The female is often seen laying her numerous eggs in damp places on the ground; the eggs are small, black, and shining; the larvæ, known as 'leather-jackets,' live in the ground, and often do damage in vegetable gardens and fields; the pupæ have spines on their abdominal segments, by which they push their way out of the ground. Of the genus *Tipula* about ninety European species are known. The largest form (*T. gigantea*) measures over an inch, and is not uncommon in Britain. *T. hortulana* is very common in gardens. The genus *Ctenophora*, commoner in wooded districts, is nearly allied. They have stouter bodies, and usually brighter colours. See MIDGE.

Dado (Ital., 'a die'), in-classical Architecture, the term applied to the cubic block which forms the body of a pedestal. It is also applied to the plane face and the series of mouldings which, in the interiors of buildings, form, as it were, a continuous pedestal. The interior dado is formed of wood, and, running round the bottom of the walls of a room, serves to protect the plaster or paper from injury. Dados and wall-linings were much used in Elizabethan and subsequent styles till this century, when, under the classic regime, they were

dispensed with. The recent revival of the 'Queen Anne' taste, however, has led to the reintroduction of dados not only in the form of wooden panelings, but also in the painting and papering of the walls.

Dædalus, a figure in Greek Mythology who personified the beginning of the arts of sculpture and architecture. He was of the old Athenian royal race of the Erechtheidæ. Having killed his nephew and pupil in envy at his growing skill, he had to flee to Crete, where he made the well-known cow for Queen Pasiphaë, and afterwards for King Minos the famous labyrinth to confine the Minotaur. Minos next imprisoned Dædalus, but he escaped with the help of Pasiphaë, and formed wings for himself and his son Icarus, with which to fly across the sea. He himself flew safe across the Ægean, but unhappily Icarus flew too near the sun, the heat of which melted the wax that fastened his wings to him, so that he dropped into the sea, and left his name to be borne by that part of the Ægean into which he fell. Dædalus made his way to Sicily. Some accounts made him first alight at Cumæ in Italy, where he dedicated his wings to Apollo. Works of art were freely ascribed to Dædalus in Greece, Italy, Libya, and the Mediterranean islands. The name *Dardala* was applied to the earlier painted and gilded wooden statues of the gods.

Daendels, HERMANN WILHELM, a Dutch general, was born in 1762 at Hattem, in Gelderland, took part in the revolutionary disturbances that broke out in Holland in 1787, and was in consequence compelled to seek refuge in France. In the campaign of 1793 he rendered important service to Dumouriez, and was elevated to the rank of a general of brigade. In 1799 he commanded one of the two divisions of the army of the Batavian republic, and in 1806 took service under the king of Holland. From 1808 to 1811 he was governor-general of the Dutch East Indian possessions, and published a work on them. On the overthrow of Napoleon, the new king of Holland, William I., intrusted Daendels with the organisation of the Dutch colonies on the coast of Africa, and there he died in June 1818.

Daffodil (corrupted from Lat. *asphodelus*), the English name of those species of *Narcissus* which have a large bell-shaped corona. The Common Daffodil (*N. pseudo-narcissus*) is a native of England and of most parts of Europe, growing in woods and hedges, and often cultivated in gardens, where it not unfrequently becomes double. It is naturalised in many places in Scotland and Ireland, but seems scarcely indigenous. From Herick's lament to Wordsworth's dancing verse we have widely varied recognitions of the familiar golden cups of the daffodil as a source alike of poetic wealth and inspiration. See NARCISSUS.

Dag, a hand-gun or thick pistol, used in the 15th and 16th centuries. It occurs in the *Spanish Tragedy* (1603).

Common Daffodil (*Narcissus pseudo-narcissus*).

Dagger, a weapon resembling a sword, but considerably smaller, being used for stabbing at close quarters. Daggers are generally two-edged, and very sharp towards the point. The *dagger of Iath* was the weapon given to the Vice in the old moralities.

Daghestan ('mountain-land'), a triangular territory of Ciscaucasia, between the Caucasus and the west coast of the Caspian Sea. Area, 11,425 sq. m.; pop. (1883) 529,705. The surface is generally mountainous, being traversed by offsets from the Caucasus; the level tracts are chiefly near the coast, and here and in the valleys the land is very fertile. The country is well watered, the climate generally mild in the lowlands, and dry, except along the coast, where the rainfall is considerable. In the highlands large flocks of sheep are herded. The chief town is Derbend (q.v.). See CAUCASUS, and SHAMYL; also Cunyngame's *Daghestan* (1872).

Dago, an island near the entrance of the Gulf of Finland, forming part of the Russian government of Esthonia, and separated by the narrow channel called Sele-sund from the island of Oesel on the south. Area, 367 sq. m.; pop. 15,000, of whom one-third are Swedes and Germans. The coast is rugged, and the soil fertile only in the south and south-west; inland there are large forests and swamps (54 sq. m.).

Dagoba, the common name in Ceylon for a Buddhist Tope (q.v.).

Dagobert was the name of several of the Merovingian kings of France, the first of the name reigning from 631 to 638. See FRANCE.

Dagon, the national god of the Philistines, half-man, half-fish, is mentioned in the Old Testament as having temples at Gaza and Ashdod. Several names of places prove that the worship of Dagon existed also in other parts of Palestine. It seems to have come to Canaan from Babylonia, the Assyrian monuments presenting a figure with the body of a man and the tail of a fish, and the cuneiform inscriptions containing the name of a god *Daken* or *Dagan*, which is probably identical with Dagon. Baudissin favours the old derivation of the name from *dag* ('fish'), with the formative syllable *-on*. Dagon and the fish-goddess Derketo or Atargatis probably answered to each other as male and female water-deities.

Daguerreotype is the name of the photographs fixed on a plate of copper thinly coated with silver by the successive action of the vapours of iodine, bromine, and mercury. Louis Daguerre, after whom the invention is named, was born in Normandy in 1789, was a scene-painter in Paris, made a famous diorama in 1822, and devoted the rest of his life mainly to perfecting the processes of photography, from 1826 till 1833 in conjunction with M. Niépce. He wrote two works on the subject, and died in the neighbourhood of Paris, 12th July 1851. The history of the invention is given at PHOTOGRAPHY.

Dahabeeah, a boat used by voyagers on the Nile, which varies in size, has one or two masts, and accommodation for from two to eight passengers, including a raised cabin on the after-deck. The boat sails, is rowed, or is dragged by ropes, according to circumstances.

Dahl, JOHANN CHRISTIAN CLAUSEN, a Norwegian landscape-painter (1788-1857), who from 1821 onward was professor of Painting at Dresden.

Dahlak, a group of three islands, with many smaller rocks, in the Red Sea, off the Bay of Massawah. They were famous in Roman times for their pearl-fisheries, but the beds have long since been exhausted and abandoned. The inhab-

itants number about 1500, are under the rule of a sheik holding authority from Egypt, and carry on a trade with the Arabian coast.

Dahlgren, KARL FREDRIK, Swedish poet and humorist, born at Stensbruk in Östergötland, 20th June 1791, studied at Upsala, and acted from 1815 as preacher at Stockholm, where he died, 2d May 1844. As a writer he made his debut in Atterbom's *Phosphorus*, and afterwards published novels, humorous tales, poems, and dramas. His works fill 5 vols. (1847-52).

Dahlgren Gun is so called after John Adolph Dahlgren (1809-70), an officer in the United States navy, by whom it was introduced in 1850. It is a muzzle-loading, cast-iron, smooth-bore gun, with great thickness of metal at the breech. Many Dahlgren guns are still in the United States service. In 1883 six of 10-inch calibre and muzzle-loaders were converted into 8-inch breech-loading rifle guns, by lining and strengthening them with wrought-iron coils.

Dahlia (*Dahlia Georgina*)—after Dahl, a Swedish botanist, and pupil of Linnæus—a genus of large perennial composites (sub-order Tubulifloræ, family Asteroideæ). It was first brought from the botanic garden of Mexico to that of Madrid in 1784, whence it reached England in

Dahlia:
A, single; B, double varieties.

1789, and France in 1802, while in 1804 Humboldt sent a fresh supply of seed to Berlin. Its extraordinary variability soon attracted the attention of florists, who brought to bear on it all the resources of selection and crossing, with so much success that by about the middle of the present century no fewer than 2000 varieties had been described, all from *D. variabilis* or *D. coccinea* or their hybrids, and chiefly from the first named. For a long time only 'double' dahlias were cultivated, but of late years the single dahlia, in which the florets of the disc remain tubular, has again come into fashion; while among double dahlias the less regular cactus dahlia is highly esteemed. They are easily cultivated, and propagated by seeds, cuttings, or tubers; but the tubers require to be taken up and stored in a dry place out of the reach of frost. They flower luxuriantly in autumn, until cut off by the first frosts. On account of the quantity of inulin in their tubers, they are cultivated for food in Mexico, but similar attempts in Europe have failed

because of their unpalatableness. See Nicholson's or other *Dictionary of Gardening*, also any florist's catalogue.

Dahlmann, FRIEDRICH CHRISTOPH, German historian, was born May 13, 1785, at Wismar. His earlier studies in Copenhagen and Halle were devoted to archæology and philology; but his attention was subsequently directed to the study of politics and the history of the middle ages. From 1813 on, he filled the chair of History at Kiel, and in 1829 was appointed to that of Political Science in Göttingen, where he published (1830) his invaluable *Quellenkunde der deutschen Geschichte*. Banished in 1837 by King Ernst August of Hanover, on account of his protest against the abolition of the Hanoverian constitution, he went to Leipzig, next to Jena, where he wrote his historical masterpiece, *Geschichte von Dänemark* (3 vols. 1840-43). In 1842 he became Professor of History at Bonn, and took a prominent part in the political affairs of Germany after the movement in 1848, heading the constitutional liberals, who were unfortunately too reasonable to be successful. At the close of the struggle, he returned to his academic duties, to which he devoted himself till his death, 5th December 1860. See *Life*, by A. Springer (2 vols. Leip. 1870-72).

Dahn, JULIUS SOPHUS FELIX, publicist, historian, and poet, was born at Hamburg, 9th February 1834, the son of a well-known actor and actress. He studied law, philosophy, and history at Munich and Berlin, became extraordinary professor at Munich (1862), next year ordinary professor at Würzburg, and in 1872 was appointed to the chair of German Jurisprudence at Königsberg. Among his contributions to public law are *Das Kriegerrecht* (1870), *Handelsrechtliche Vorträge* (1875), *Deutsches Rechtsbuch* (1877), and *Deutsches Privatrecht* (1878). Of his historical works the chief are *Prokopius von Caisarea* (1865), *Die Könige der Germanen* (1861-71), *Westgotische Studien* (1874), *Langobardische Studien* (1876), *Urgeschichte der germanischen und romanischen Völker* (3 vols. 1881-84), and *Geschichte der deutschen Urzeit* (1885). Dahn's versatility is as remarkable as his erudition is profound. He has written a series of popular historical romances, and of lyrical and dramatic poems. Of the former may here be named, *Ein Kampf um Rom* (1876), one of the most powerful of modern German novels, *Othins Trost* (1880), and *Die Kreuzfahrer* (1885).

Dahna. See ARABIA, Vol. I. p. 362.

Dahomey, a kingdom of Western Africa, extending inland from the Slave Coast, in about 6° 15'—7° 30' N. lat., and 1° 30'—2° 30' E. long. Its limits, however, are not clearly defined, and it is only certain that their extent has been greatly overestimated; the seaboard is confined to a district of 35 miles, between Cotanu and Mount Pulloy, and elsewhere the kingdom is encircled by tribes either subjugated or in active hostility. The boundaries of Dahomey and Ashanti do not meet to the north of the Avon lagoon, as shown on some maps. The long lagoon which, shut in from the ocean by a protecting bank of sand, affords an easy route along nearly the whole of this coast, extends in Dahomey, from its western frontier almost to the Denham lagoon, in the east. About midway is the port of Whydah, whence a road extends inland to Abomey, a distance of 65 miles. Dense forests and dismal swamps cover nearly two-thirds of this distance, but from the Great Swamp of Agrimé vast undulating plains rise for many miles, in the direction of the Kong Mountains. The Avon and Denham lagoons receive the rivers of the country, none of which are very important. The soil is a rich, red-coloured clay, and is extremely fertile.

Groves of oil-palms encircle each town, and palm-oil is made in large quantities. Maize, beans, and peas, as well as cassava, yams, sweet potatoes, limes, oranges, pine-apples, and other tropical fruits, grow in splendid luxuriance; cotton, sugar, and spices of all kinds are also grown, and sheep, goats, swine, and poultry are raised, though not in large numbers. Cotton cloth is made, and weapons and tools are forged from native iron.

The people are negroes, of the Ewe group, generally of small stature, but very robust and active. They are sociable, equally fond of dancing and of rum, but warlike and prone to theft. The Dahoman kingdom dates from the beginning of the 18th century, and reached its zenith under Gezo, who ruled from about 1818 to 1858. Since then its power has declined, and even its population has fallen off; but little reliance can be placed on the estimates of the numbers, which range from 150,000 to 900,000, the former number being probably most correct. The army may be taken at 10,000 men; the Amazons (devoted to celibacy), who are distinguished for their bravery and ferocity, may perhaps be limited to 1000. Fetish-worship prevails, taking the form of serpent-worship along the coast; a temple with over a hundred of these sacred snakes exists at Whydah. The king is the most absolute of despots. Wholesale murder is one of the chief features in religious and state ceremonies; but, according to Sir Richard Burton, who visited Dahomey in 1863, the number of the victims has been greatly exaggerated, and they are principally foreign captives. Still, as many as 500 human victims have been sacrificed at one of the grand 'customs' which take place every October. The revenue formerly depended greatly upon the sale of slaves; but the vigilance of the cruisers employed to prevent the traffic has ruined the trade. Hence the monster slave-hunts which periodically took place are a thing of the past. In 1876 the coast of Dahomey was placed under a strict blockade by Great Britain, on account of an outrage on a British subject, for which the king of Dahomey refused satisfaction.—ABOMEY, the capital, stands on a rolling plain, nearly surrounded by marshes. It is about 8 miles in circumference, and is surrounded by a deep ditch and clay walls, pierced by six gates. There are three palaces belonging to the king here, several large squares, and a number of farms, which are cultivated within the city. Pop. about 30,000. Whydah has a pop. of about 12,000; and Cana, where is the king's country residence, 8 miles SE. of Abomey by a good road, about 5000. See Burton's *Mission to Gelele, King of Dahomey* (new ed. 1864); Skertchly, *Dahomey as it is* (1874); and Bouche, *La Côte des Esclaves et le Dahomey* (Paris, 1885).

Dahra, a district of Algeria, to the east of Mortaganem, and near the coast. In June 1845 a tribe of Kabyles took refuge in a cave here, and on their repeatedly refusing to surrender, Pélissier, the French commander, caused them to be suffocated by kindling large fires of green branches at the mouth of the cave. Some 500 Kabyles thus met their death. See PÉLISSIER.

Daimiel, a town of Spain, 28 miles ENE. of Ciudad Real by rail, with manufactures of woollens, brandy, &c. Pop. 9652.

Daimios, the old territorial nobles of Japan, who, before the revolution of 1871, enjoyed almost absolute power within their own domains, paying little more than nominal allegiance to the mikado. At the restoration of the mikado, however, they were obliged to surrender their castles and muster-rolls to the government, who took away their privileges and relieved them of the duty of paying allowances to their retainers. See JAPAN.

Dairy is a word used in speaking of a number of cows kept for milking purposes, or to indicate the buildings in which Milk (q.v.) is sold or manufactured into Cheese (q.v.) or Butter (q.v.). The byre or cow-house should be connected by a covered way with the milk-house proper, and the arrangements for ventilation made so perfect that it should not be possible to detect in the vicinity of the milk any smell from the cows, pigs, or other source. The milk-house should on no pretext be made a common storeroom for meat, game, onions, or any material which will taint the air and then the milk and the cheese or butter, as the case may be. The first essential in a dairy is the absolute cleanness not only of the floors and walls of the building, but of all its furnishings. This is secured by daily washing and by the scalding or steaming of all vessels or implements which come in contact with milk or its products; the object being to destroy the microbes which live and multiply in milk and bring about its acidity and decay. The thermometer in the dairy should stand at 55° F. in summer, and 60° F. in winter. At temperatures higher than these milk is liable to spoil, owing to the greater activity of the above-mentioned germs; many degrees below this it gets chilled, and will not manipulate satisfactorily. An abundant supply of pure water is necessary, and means for boiling water must also be provided, not only to secure scalding water for washing, but to raise, when necessary, the temperature of the products of milk during manufacture, or maintain a suitably high temperature in the air of the cheese-room or the milk-house. A small steam or gas engine is frequently employed in a dairy conducted on a large scale, to supply the power necessary for a centrifugal Cream Separator (q.v.), also for churning whole milk or cream, and at times for driving the compressed-air refrigerator. The latter is used to lower the temperature of vaults in which fresh, summer-made butter is stored until the winter season, when the prices for good 'grass' butter are high. As the cost of the necessary machinery is considerable, the method can only be made to pay when the business is extensive.

Dairying has developed much within recent years. The growing demand for milk in large towns has increased the volume of the milk-trade, and modified the system of management. Summer dairying, while suitable for the making of cheese, and so far for butter also, must be supplemented by winter dairying to keep up the supply of milk and fresh butter throughout the year. For summer dairying it is usually arranged that the cows calve during March, April, and May, so that they go to pasture when they are coming to the period at which, with a proper supply of succulent food and suitable surroundings, they should develop their greatest yield of milk. They lie out day and night, and have the whole summer and early autumn before them—the period in which grass, the most natural food of a cow, is most abundant, best, and cheapest. In some instances the grass is supplemented by 2 or 3 lb. a day of cotton-seed or other cake, and when the grass begins to fail in autumn, some variety of green food, as cabbages, rape, vetches, &c. As frost begins to appear the cows are housed at night, and in spite of liberal and careful feeding, fall off in their yield of milk. Nevertheless, it is the better practice to house them in good time, because they keep in better condition during winter than if left out too long, and for the few remaining weeks of the milking period they give a larger average return. All naturally 'dry off,' some more rapidly than others. Milking should be stopped abruptly at the end of the year—experience points to this being the best and simplest method of drying off cows at this season. After two or three months of rest,

the cows calve, and this goes on year by year from the age of two or three (depending upon size and condition) until ten years old, when all should, without exception, be replaced by heifers. A ring appears on the horn to mark each year after the third year, and by this the age can be determined.

Where winter dairying is also practised, the cows are made to calve at all times of the year, so that a number come in possibly every week, to replace others that have ceased to milk satisfactorily. The temperature of the cow-house has to be maintained at such a high point, to keep up the full flow of milk during winter, and the feeding is made so forcing and unnatural that the constitutions of cows would show the effects of this high-pressure system if they were kept to calve another year. In consequence, few farmers who adopt this system of management retain their cows more than one milking period. They shut them in the house both summer and winter, and give a full supply of food all the while, to maintain their condition. Some send them to auction as soon as the yield of milk falls to the net cost of its production. Others attempt to feed the cows after this until they put on flesh, so that they command a higher total price and a higher rate per stone in the fat market than ordinary milking cows. Unquestionably the system of changing cows after one milking period pays farmers who are favourably situated for the disposal of milk to private families, better than keeping them for a number of years and 'bringing them round' to calve each season; yet there is one serious drawback as regards the suspension of the improvement of dairy cattle, by neglecting the selection of calves for rearing from the best milking mothers. The system is only possible, without doing serious injury to the breeds of cattle, because it is not general throughout the country, but confined to dairies supplying milk to large centres of population.

Eight to ten cows is a sufficient number for each milker, and the operation should be performed as quietly and as expeditiously as possible. Men are usually employed in England, and women in Scotland. When cows give a large flow of milk, or when it is wanted for town consumption, milking is done thrice daily; but in the great majority of cases throughout the country it is only performed morning and evening. Heavy milking cows consume a large quantity of water, which should be supplied to them at least twice daily. Cows not in milk are often allowed to drink only once a day, though it would be better to let them do so twice. To offer tepid water to a cow immediately after calving is an unnatural and altogether unnecessary precaution; she should have cold, but not iced, water in small quantities, and given frequently until she is satisfied. Cows consuming a large amount of sloppy food and roots do not require much water.

It is important that the water should be pure and clean. Outbreaks of typhoid fever among children have been traced to cows drinking water contaminated with the germs of this disease. Though sewage irrigation grass is extensively used, under the 'soiling' system, by cowfeeders near to towns (Edinburgh, for example), no injurious results have been traced to this practice. Irrigation grass has been largely superseded within recent years by supplies of better quality got from immense crops of Italian ryegrass (*Lolium italicum*), grown without irrigation by means of heavy and repeated dressings of nitrate of soda. In no place can this system be seen to greater perfection than around Edinburgh. In some parts clover and vetches take the place of ryegrass. Succulent food is essential for the production of large returns of milk. As the grass season ends in October, the succulent portion of

food may be derived from brewers' and distillers' grains (1 bushel per day being a full allowance for a large cow), and from turnips—a favourite variety at present being the Foxterton hybrid. Turnips, when given in excessive quantities, produce an objectionable taste in the milk and butter, but as an ingredient in a liberal and well-balanced diet they may be used with impunity, where milk is the product wanted. Swedes and mangels are not so liable as common turnips to taint cow products, and as they keep well when stored, they are reserved for use during the winter and spring months. Cows in full milk require a daily allowance of perhaps 5 to 8 lb. of concentrated food—a mixture of various farinaceous meals and oil-seed cakes along with bran, which acts as a corrective as well as a food substance. Bean meal is prominent among the meals for encouraging a flow of rich milk and at the same time maintaining the condition of the cow. Turnips, unless liberally supplemented, are liable to reduce the condition. The ingredients in the food mixture should be determined by their market prices from time to time. There is a decided advantage in giving a mixed food, as compared with one variety, provided a proper proportion is secured between the albuminoids and the carbohydrates—one to five is a good ordinary average to aim at under ordinary circumstances, having estimated oil as equivalent to two and a half times its weight of starch. Not only must the proportion of the components of a food mixture be adjusted, but the total bulk of the food must be great enough to distend the stomach sufficiently to promote healthy action in the digestive system. About 30 lb. of dry food substance is a good allowance for a healthy milking cow of one of our large breeds. If that were given entirely in the form of concentrated food, such as meal and cake, the animal could not chew the cud, and impaction of the rumen would result. The practice of chaffing straw into very short lengths is associated with the same danger. Dry fodder, more especially straw, is vastly improved for milk cows by cooking—either steaming it, or throwing warm water over it, and covering it up for a few hours. In spring, before the grass comes, the flow of milk in newly-calved cows is often largely developed and maintained by treating hay in this fashion, and supplying them with the hay tea and the solid residue mixed with meal. When very large quantities of concentrated food are used, it is safer to add to the daily allowance of each cow from 1 to 2 lb. of molasses, which supplies not only a valuable ingredient of food, but maintains a healthy action in the organs of digestion. Without some such precaution the percentages of ailments and deaths, in the case of cows kept under a high-pressure system of feeding, are likely to be considerably above an average. Epsom salts should never be given to a cow in milk, as they permanently reduce the yield for the season; 8 to 10 lb. of warm treacle is more rapid in its action, safe, and free from injurious after-consequences. Bought concentrated food has another function than the above to perform. Its ash ingredients which pass away in the manure make good to the land the considerable loss of bone-earth and other valuable substances which are removed in dairy products—more especially milk. See CATTLE, BUTTER, CHEESE, MILK.

Dairy Factories. Dairying, as a special business, has been extensively developed during the latter half of the 19th century. Copyright 1888 in U.S. by J. B. Lippincott and Company.

being exceedingly favourable in regard to the quality and increased market value of the product (which was then cheese only), many other factories were organised, until in 1866 there were nearly 500 of them in operation in the state mentioned, the cost of these being about \$1,000,000 (£200,000), with a stock of cows worth, at the then low valuation, at least \$10,000,000. The farms thus associated were then worth, for the million acres covered by them, not more than \$40,000,000 (£8,000,000), or an average of \$40 per acre. Five years later there were factories in several of the states and also in Canada; the list comprising 946 in the state of New York, 103 in Ohio, 46 in Illinois, 5 in Kentucky, 4 in Minnesota, 34 in Wisconsin, 26 in Massachusetts, 32 in Vermont, 14 in Pennsylvania, 7 in Iowa, 2 in Indiana, and 1 each in Virginia, North Carolina, Tennessee, Kansas, and Connecticut. This associated industry became known in foreign countries as the 'American system of dairying,' and was quickly introduced into England, Sweden, Denmark, Switzerland, Holland, and other countries where the dairy business was carried on extensively, but it has not increased to anything like the extent it has in America. Very soon the manufacture of butter was introduced into the factories, as well as into special establishments for butter-making alone, the latter being called creameries, in contradistinction to the factories where cheese only was made, or where butter and skim-milk cheese were made, or where the skim-milk was adulterated with fats and oils of various kinds, as substitutes for cream. It was about this time (1872) that the French oleo-margarine (a preparation of beef-fat) was introduced into the American dairy as a substitute for pure butter fat in the manufacture of cheese. It is a disagreeable truth to confess that this fraudulent 'dairy (?) product,' as it is called, still maintains a firm hold upon American dairying, and largely as a distinct fraud, made use of for the purpose of making and selling adulterated cheese, and butter as well, for a pure product. And in addition to the fat of beeves, lard and cotton-seed oil are extensively used. Laws recently passed in several of the states and in the United States congress forbid the sale of butter so adulterated under heavy penalties, but no legislation as yet protects cheese from the fraudulent mixture. This stigma upon the American dairy (Canada, it may be said, is happily free from it) remains to this time a reproach and severe pecuniary damage to the dairy business.

American dairy cheese is made under the well-known Cheddar system, so called, which is prevalent in parts of England, and in Ayrshire and other localities in Scotland. This is the American cheese which is so well known and highly regarded in Great Britain, when purely made under the best system of management. But a considerable variety of cheese is now made in imitation of foreign kinds, and is used by the foreign-born citizens, who have not forgotten their acquired taste for the old home-made cheese.

Creameries, or butter-factories, came into use with the cheese-factories, but were not numerous until a way was found to utilise the skim-milk by adding artificial fats to it. Then the combined butter and cheese factory turned out its butter and its full-milk cheese together. This questionable method of business, however, became unpopular, and actual creameries came into vogue, and have rapidly increased during the past few years. In 1880 there were 3932 cheese and butter factories in the United States; in 1888 there were at least 5000, the largest numerical increase having been in creameries. In the creamery, the cream gathered from 600 or 800 cows is worked up by one skilled

butter-maker, and the product is a good article of even quality all through; it is made in sufficient quantity for shipment and sale under the best conditions, and hence it commands a higher price than the best ordinary farm-dairy butter. It is made with the best apparatus, is packed and shipped in cold-storage or refrigerator cars, and reaches the domestic consumer within a week after it is made; and the foreign purchaser may have it upon his table within two weeks of the churning in the creamery, more than 4000 miles distant. These are advantages which the solitary butter-maker cannot secure; hence he can only get the creamery price by securing special customers near his dairy. A few so-called fancy dairies are able to secure 40, 50, or even 75 cents (1s. 8d. to 3s.) per pound for their butter, but even the best ordinary farm-dairy butter sells at a lower price than creamery butter, and fully three-fourths of it sells for less than half the price of the other.

American creamery butter is made by the deep setting system, borrowed from the Swedish method, and improved by American ingenuity. The milk is strained from the pail into cans 9 inches in diameter and 20 inches deep. These are set in tanks of water cooled by ice to 45°. At the end of twelve to twenty-four hours the cream has separated, and the milk is drawn off by a tap in the bottom of the can, view being given by a strip of glass let into the side of the can. The cream is then drawn off by itself. For the use of the creamery the quantity of cream is measured by the inch, and is paid for on the basis of so many inches to the pound of butter. One hundred and thirteen cubic inches of cream is taken as the standard in this respect. The creamery gathers the cream once a day, and secures it perfectly sweet, while the skim-milk is also left sweet for the feeding of calves, for sale for consumption, or for the making of pork. The cream is kept until it is slightly acid before it is churned, making thus a quality of butter which keeps better and longer than that made from sweet cream. The churns most popular are those without any dash, being a cubical box turning on an axis passing through diagonal corners; or a barrel turning on an axis passing through its centre sidewise; or an oblong square box oscillating endwise in swinging supports. The action of churning thus consists of a dashing of the cream violently against the sides or ends of the churn, and, by concussion, causing the globules of fat in the cream to adhere together, and gradually coalesce and form small grains of butter. When these grains are as large as wheat-grains, or peas at the largest, the buttermilk is drawn off, cold water or weak brine is poured into the churn, and the churn is moved gently, to agitate and wash the butter. When the butter has been completely freed from milk, and no longer clouds the water, it is drained, and salted with finely-ground pure salt, at the rate of from $\frac{1}{2}$ oz. to 1 oz. to the pound of butter. The salt is easily incorporated with the small grains of butter, and after a rest of a few hours for the salt to absorb the excess of moisture from the butter and become completely dissolved, a butter-worker is used to press the butter, make it solid and even in texture, and as dry as possible. It is then packed in new spruce or oak tubs, or pails, of 20 to 50 lb., for domestic sale, or in 100-lb. firkins for export.

The dairy interest has reached vast proportions in America and Canada. At least 1,500,000 farms, with 10,000,000 cows and 100,000,000 acres of land, are devoted more or less closely to the various branches of the industry. In the most populous of the states, where the dairy is the principal agricultural employment, good dairy farms are valued at \$100 (£20) per acre and upwards, as the buildings may be more valuable than

the average. The land held to be most suitable for the dairy is a rich limestone loam or gravel, that is productive of the best variety of grasses, especially the so-called blue grass (*Poa pratensis*), which affords the best pasturage. The best dairy districts are in the states of Vermont, New York, Pennsylvania, Ohio, Iowa, Wisconsin, Illinois, and the province of Ontario, in Canada.

The cows mostly kept upon dairy farms are the Dutch or North Holland, commonly called Holstein or Holstein-Friesian, Shorthorns, Ayrshire, the half or higher bred grades of these, and the common 'native' cows, the descendants of the promiscuous mixture of the various races of cattle brought into America. The most popular of these is the grade shorthorn, which may be purchased when in fresh milk; the Dutch cow is next in popular estimation, but it is scarce and high-priced, and is much less used. The average yield of these cows varies from 6000 to 8000 lb. of milk per year, or between calves, where calves are bred; the largest yield of the shorthorn and its grades averages 50 lb. daily, that of the Dutch cows is somewhat greater, and a few of the best have a record of more than 24,000 lb. of milk between calves and within a year. These cows can be kept with profit only upon high feeding and the best of pasture. For the butter-dairy the Jersey breed and its grades are the most profitable, and American pastures are now quite thickly sprinkled with the Jersey colours. Ayrshires come next, and the Devon follows in favour; but of necessity the common native and much cheaper cow forms the rank and file of the dairy herds.

In America the whole of the work of caring for the cows, feeding and milking them, is done by men. The feeding consists of pasturing wholly; pasturing with partial soiling, or full soiling in the summer; and feeding upon hay and meals of various kinds with pulped roots or silage in the winter. A large number of dairies are devoted to making butter in the winter, by which a higher price is obtained for the product, and leisure is secured in the summer for the growth of the feeding crops for use in the winter. With the rapid rise in the value of farms suited to the dairy, pasturing is found to be too costly for the largest profit, and partial soiling is almost universally resorted to. Complete soiling, by which one cow may be kept on the product of one acre of land all the year, is practised in some of the best of the fine-butter dairies, where land is worth \$200 per acre or more, and where pure-bred Jersey, Guernsey, or Ayrshire cows of high value are kept, a yield of 12 to 14 lb. of butter per week being obtained by the high feeding of these cows. One of these cows, a Jersey, recently produced 49 lb. of butter in a week, under a forced test, while from 14 lb. to 24 lb. of butter weekly has been given by more than 100 Jersey cows now living. This, however, is an example of what is known as fancy dairying, which is closely connected with breeding cows for sale at high prices. In a good working dairy a cow is required to yield 7 to 10 lb. of butter weekly in the height of the season, and at least 200 to 250 lb. in the season.

The average feeding of a dairy cow in the summer consists of the best pasture that can be afforded, with some fresh green fodder as soon as the great heat of the summer hardens the grass, and from 2 to 12 quarts of ground feed—ground corn and oats, bran, cotton-seed meal, or linseed meal. A very common method of feeding is to give 2 or 3 quarts of mixed corn meal and bran, with a quart of cotton-seed meal at each milking time, the cows generally being brought to the barn to be milked. In winter, hay of clover and timothy grass mixed, with the same quantity above mentioned of meal and a peck of brewers' grains, is

a common ration for cows kept in milk-dairies; brewers' grains are not thought favourably of in cheese or butter dairies, where any food that readily becomes sour or tainted is scrupulously avoided, and is wholly prohibited by the owners of factories or creameries, and by condensers of milk. Roots of various kinds are rarely used in America, the hot, dry summer climate and the greater ease of growing the equally valuable feeding crop, maize (commonly called corn), combining to make root-crops unpopular. When roots are grown, the long red or the yellow globe mangels are preferred.

The use of ensilage has been found very convenient in the dairy, and this practice is rapidly extending. In the dairy districts of Wisconsin at least 2000 silos were built in 1888, the serious damage to the feeding crops by the dry season of the previous year having induced dairymen to secure ample feed by growing corn—which suffers little from drought, and to some extent enjoys dry, hot weather—and preserving it green in silos. It is quite certain that the cheapness and ease of production of this grand fodder crop has given a greater stimulus to the American dairy than any other favourable circumstance. The abundance and cheapness of the grain (corn), and also of bran, enable American dairymen to produce cheap milk, cheese, and butter; and there is no other class of American farmers who enjoy equal comfort, and even wealth.

Dais (Old Fr. *deis*, *dois*, from Lat. *discus*, 'a quoit,' 'platter'; in late Lat. 'a table'), a term used with considerable latitude by medieval writers. Its most usual significations are the following: (1) A canopy over an altar, shrine, font, throne, stall, chair, statue, or the like; the term being applied to the canopy without regard to the materials of which it was composed, which might be cloth, wood, stone, metal, or other substance; (2) the chief seat at the high table in a hall, with the canopy covering it; (3) the high table itself; (4) the raised portion of the floor, or *estrade*, on which the high table stood, and which divided the upper from the lower portion of the hall; (5) a cloth of state for covering a throne or table.

Daisy (*Bellis*), a genus of tubulifloral composites (family Asteroidæ) characterised by its conical receptacle and absence of pappus. The seven or eight species are palaearctic, save *B. integrifolia* of Tennessee and Arkansas. The familiar species, *B. perennis*, needs no description, nor can any one have failed to notice its habit of closing at night. Double varieties, crimson, pink, white, or striped, are common in gardens, and are frequently of such exuberantly vegetative habit as to produce smaller heads in the axils of the involucre bracts of the main capitulum, whence the popular name of *Hen-and-chickens*. A handsome variegated variety is called *aurubæfolia*. The characteristic beauty and almost perennial profusion of blossom have made this commonest of flowers the prime favourite alike of childish and poetic garlands, and invested its many names (Eng. *Day's eye*, Scot. *Gowan*, Fr. *Marguerite*, &c.) with such an unequalled wealth of associations that it must here suffice only to name Chaucer and Burns as foremost laureates of a ceaseless tribute of admiring song. The Ox-eye Daisy is a *Chrysanthemum* (q.v.).

Dāk, or **DAWK**, the mail-post of India; also, travelling by Palanquin (q.v.). See BUNGALOW.

Dako'ta, a territory of the United States, between the parallels of 42° 28' and 49° N. lat., and 96° 25' and 104° 5' W. long. It is bounded N. by Assinibolia and Manitoba (Canada); E. by Minnesota and Iowa; S. by Nebraska; and W. by Montana and Wyoming. Area, 150,932

sq. miles; about one-fourth larger than Great Britain and Ireland. Four-fifths of the surface is an undulating plain. A belt of high plateau, the Coteau du Missouri, traverses the territory from north-west to south-east; and a similar but smaller ridge or divide lies east of the James River valley. The great river Missouri flows south-eastward across Dakota; and the country west of that stream is more broken and better timbered than the rest. To the south-west lie the Black Hills, a rugged and mountainous region (3200 sq. m.), and well wooded. Their highest point, Harney Peak, is 8200 feet high. The Turtle Mountains in the north are crossed by the Canadian boundary; their area in Dakota is but 800 sq. m., and their highest elevation 2300 feet. The geological features of Dakota are full of variety and interest. A very large proportion of the surface is covered by glacial and alluvial drift, and much of the country bears evidence of having been more than once submerged. During the Silurian age a shallow sea or saline lake must have rolled over it; while there is evidence that at about the end of the glacial period it was either the bed of a great lake, or at least was very largely covered with lacustrine waters. At present the lakes are all relatively small, except Devil's Lake, or Minniwaukon, in the north, which, like many others of this region, has no outlet. Its waters are therefore saline, but it is inhabited by fishes of various fresh-water species. About one-third of the area of Dakota, chiefly towards the north-west, is believed to be underlaid with beds of workable lignite, well adapted to use as a domestic fuel; and the spontaneous firing of the lignite beds has probably been a large factor in the development of the 'bad lands' of Dakota, which are covered with rocks of most fantastic shapes. Natural fuel-gas has been obtained by boring at several points. Among the building-stones are quartzite, jasper, and granite in the south-east, and sandstone, marble, and granite in the south-west. Fictile clays, gypsum, cement, chalk, mica, and other useful minerals are found in many places. Medicinal and thermal springs are found in the south-west, where the Black Hills afford much gold and silver, as well as tin, antimony, lead, mica, copper, and other minerals. The tin-mines are the only ones of any extent ever worked in America; and some of the gold-mines are among the most extensive in the world. In the ten years 1877-87 the gold and silver production of the Black Hills amounted to \$33,770,000.

The climate of Dakota presents some remarkable features. The winters are cold, but so dry and sunny that the cold is usually borne without great suffering, except during the blizzards (see BLIZZARD) which are occasionally experienced. The summer days are warm and often windy, but the nights are ordinarily calm and cool. The climate is everywhere remarkably healthful; malarial diseases are nearly unknown. The rainfall is relatively low, but the copious saline elements in the soil, with the generally level surface and the coolness of the climate, tend to the retention of moisture; hence the rainfall is usually ample for the production of all the ordinary crops. The planting of forests has been greatly encouraged by local and national legislation. The Missouri River is the principal stream; it is usually navigable for eight months in the year. The other important rivers are the James, noted for the fertility of its valley; the navigable Red River, famous for its rich alluvial basin; the Big Sioux, Vermilion, White, Cheyenne, Bad, Moreau, Grand, Cannon Ball, Heart, Little Missouri, Maple, and the Mouse or Souris. Parts of the north and north-east sections are tributary to Hudson Bay through the

Red River; but the greater part of the territory belongs to the Mississippi valley. The leading agricultural products are spring wheat of high grade, the staple product of the Red River basin; maize, which does well throughout a large part of the territory; flax, raised chiefly for the oil of its seed; oats, rye, barley, buckwheat, potatoes, and hay. Fruit-growing is receiving a rapid development. Hops grow wild and of good quality in certain sections. A very important interest is the rearing of live-stock; the cattle-ranch system prevailing in the less settled districts. The Bad Lands, formerly regarded as worthless, are now especially valued as suitable ground for cattle-raising. A country like Dakota, but a few years since the abode of millions of buffalo and countless antelope, must of necessity be well adapted to grazing. A very considerable proportion of the area is still occupied by Indian reservations; immigration has gone on at a rapid rate, and the portion still open for occupation by actual settlers had, by 1888, been reduced to one-fourth of the territory. The larger proportion of the incoming settlers are from the older northern states and from Canada; but many come from Scandinavia, Britain, and Germany, and not a few (Mennonites) from Russia. The manufacturing interests of Dakota are for a new agricultural state singularly diversified and extensive. Railways, including the North Pacific line, have been pushed extensively, and their construction has preceded, not followed, the settlement of the country. Abundant provision has been made for the educational needs of the country, and several colleges and normal schools and a universally prevalent system of free schools have been established. Among the principal towns are Bismarck (pop. 4500), the capital; Huron (4000); Aberdeen (6000); Fargo, in the north-east (10,000); Watertown (4500); Mitchell (5000); Grand Forks (7500); Deadwood (5000) and Rapid City, in the Black Hills (5000); Sioux Falls, in the south-east (11,000); and Yankton (5000). Pop. (1860) 4837; (1870) 14,181; (1880) 135,177; (1885) 415,623; (1888) 640,823.

History.—The first real and permanent white settlement in Dakota was probably established by French Canadian settlers near Pembina about 1780. Lord Selkirk in 1812, by a mistake, built his fort of Pembina south of the Canadian line; there were fur-trading posts established at least as early as 1808. By a treaty with the Dakota Indians in 1851 a large part of the country was opened to white settlement. The territory was established and organised in 1861. Yankton was the capital until 1883, when Bismarck became the seat of government. During the congressional session of 1888-89 it was in contemplation to admit the whole or a portion of Dakota as a state.

Dalai'-Lama. See LAMAISM.

Dalbattie, a town of Kirkcudbrightshire, near Urr Water, 15 miles SW. of Dumfries. Founded in 1780, it owed its importance to the neighbouring Craignair granite-quarries (now to a large extent exhausted), and to its polishing-works, which furnished granite for the Liverpool and Odessa Docks, the Thames Embankment, and many more works, both at home and abroad. Pop. (1841) 1430; (1881) 3861.

Dalberg, the name of an ancient and noble German family which long held by hereditary right the office of chamberlain to the archbishopric of Worms. So great was the renown of the Dalberg family, that at every coronation of a German emperor the royal herald exclaimed: 'Is there no Dalberg here?' whereupon the representative of the family kneeled, and received from the new emperor the dignity of 'first knight of the empire.'

One of the most eminent members of this family was Karl Theodor (1744-1817), the last prince-bishop of Mainz, who, trained for the church, held numerous high offices, and ultimately became elector of Mainz, chancellor of the empire, and primate of Germany. He was a friend of Wieland, Herder, Goethe, and Schiller, and wrote works on history, philosophy, and æsthetics.

Dalbergia, a tropical genus of papilionaceous trees and climbers. Some of them are valuable timber-trees, particularly the Sissoo of Bengal (*D. Sissoo*) and *D. melanoxylon* of Senegal (Senegal Ebony, q.v.). *D. monetaria*, of Surinam, yields a resin very similar to Dragon's Blood.

Dale, DAVID, was born 6th January 1739 at Stewarton in Ayrshire. Early apprenticed to a Paisley weaver, he afterwards travelled some time round the country, buying up the homespun linen yarn, next became clerk to a silk-mercier, then an importer of French and Dutch yarns. On Arkwright's visiting Scotland it was agreed that he and Dale should engage in cotton-spinning together at New Lanark near the Falls of Clyde. There Dale built mills, and became prosperous. In 1799 he sold these mills to a Manchester company whose manager was the famous Robert Owen, husband of Dale's daughter. Dale spent his last years in active works of benevolence in Glasgow, and in preaching to a church of his own which called itself the 'Old Independents.' He died at Glasgow, 17th March 1806.

Dalecarlia, or DALARNÉ (signifying 'valley-country'), an old province of central Sweden, now forming the län or county of Kopparberg. The Dalecarlians are celebrated for the part they took under Gustavus Vasa in freeing their country from the yoke of Christian II. of Denmark.

D'Alembert, JEAN LE ROND, mathematician and encyclopædist, was born in Paris, November 16, 1717, and was found the day after his birth near the church of St Jean-le-Rond, from which he derived his name—the surname he himself added long after. He was the illegitimate son of Madame de Tencin and the Chevalier Destouches, and was brought up by the wife of a poor glazier; but his father, without publicly acknowledging the paternity, secured to him an allowance of 1200 francs a year. At twelve the boy entered the Collège Mazarin, where he soon showed his lifelong passion for mathematical studies. On leaving college, he returned to the humble home of his kind foster-mother, where he continued to live and pursue his favourite studies for thirty years, broken only by two ineffectual attempts to earn a living by law and medicine. 'You will never,' said his foster-mother, 'be anything but a philosopher; and what is a philosopher, but a fool who torments himself during his life that people may talk about him when he is dead?' His first distinction was admission at twenty-three to the Academy of Sciences. Two years later appeared his *Traité de Dynamique*, which reduces all the laws of motion to the consideration of Equilibrium, thereby making an epoch in mechanical philosophy. Later works were *Réflexions sur le Cause générale des Vents*, which gained the prize of the Academy of Berlin, 1746, and which contains the first conception and use of the Calculus of Partial Differences; *Traité de l'Équilibre et du Mouvement des Fluides* (1744); *Recherches sur la Précession des Équinoxes et sur la Mutation de l'Axe de la Terre* (1749); and *Recherches sur Différents Points Importants du Système du Monde* (1754). His *Opuscules Mathématiques* (8 vols. 1761-80) contain an immense number of memoirs, some on new subjects, some containing developments of his previous works.

But D'Alembert did not confine himself to

physical science. For the great *Encyclopédie* planned by Diderot he wrote the famous *Discours Préliminaire*, a noble tribute to literature and philosophy, a model of lucid and eloquent exposition, although its classification of the sciences is open to question. Besides numerous articles in the *Encyclopédie* (the mathematical portion of which he edited), he published books on philosophy, literary criticism, the theory of music, and a treatise, *Sur la Destruction des Jésuites* (1765), which involved him in controversy. He became secretary to the Academy in 1772, and thereafter he wrote the lives of all the members deceased between 1700 and that year—one of the most pleasing of his works. His literary works have been published in a collected form, new edition, by Bossange (Paris, 5 vols. 1821). This edition contains his correspondence with Voltaire and the king of Prussia. His scientific works have never been collected.

So genuine was D'Alembert's love of independence that wealth and rank had no fascination for him. Frederick II. of Prussia offered him the presidency of the Academy of Berlin in 1752, but he declined to leave France, and only accepted a subsequent offer of a pension of 1200 francs. The king of France granted him a similar sum. In 1762 Catharine II. of Russia invited him, through her ambassador, to undertake the education of her son, with a salary of 100,000 francs; and when he declined, she wrote him an autograph letter, urging that to refuse to contribute to the education of a whole nation was inconsistent with his own principles; and inviting him, if he could not reconcile himself to the breaking-off of his pursuits and friendships, to bring all his friends with him, and she would provide both for them and for him everything they could desire. But he remained steadfast. D'Alembert never married. He was tenderly attached for many years to Mademoiselle Espinasse, with whom he lived in the same house in Platonic affection for nearly a dozen years, but who was scarce worthy of his devotion. Her death in 1776 was a crushing blow to the philosopher. His own health began to give way; for he was suffering from the stone, and would not consent to an operation. He died October 29, 1783.

Dalgarno, GEORGE, an almost forgotten but very able author, was born at Aberdeen about 1626, studied at Marischal College, and afterwards kept a school in Oxford for thirty years, where he died August 28, 1687. He deserves to be remembered for two remarkable works—the *Ars Signorum, vulgo Character Universalis et Lingua Philosophica* (1661), and *Didascalocophus, or the Deaf and Dumb Man's Tutor* (1680). The former is a very ingenious attempt to represent and classify ideas by specific arbitrary characters irrespective of words. It contains the germs of Bishop Wilkins's subsequent speculations in his work, *A Real Character and a Philosophical Language* (1668). Leibnitz has repeatedly alluded to it in complimentary terms. The latter work has for its design 'to bring the way of teaching a deaf man to read and write as near as possible to that of teaching young ones to speak and understand their mother-tongue.'

Dalhousie, JAMES ANDREW BROWN-RAMSAY, MARQUIS OF, Governor-general of India, and 'greatest of Indian proconsuls,' was the third son of the ninth Earl of Dalhousie, and was born April 22, 1812, at Dalhousie Castle, Midlothian. He was educated at Harrow, and graduated at Christ Church, Oxford. In 1832, by the death of his only remaining brother, he succeeded to the courtesy title of Lord Ramsay. In 1835 he stood unsuccessfully for Edinburgh in the Conservative interest; in 1837

was elected for Haddingtonshire. On the death of his father in 1838 he entered the House of Peers as Earl of Dalhousie. In 1843 Sir Robert Peel appointed him Vice-president of the Board of Trade, and in 1845 he succeeded Mr Gladstone as President of the Board. The 'railway mania' threw an immense amount of labour and responsibility upon his department; but the energy, industry, and administrative ability he displayed in his office, no less than his readiness and fluency in parliament, marked him out for the highest offices in the state. When Peel resigned office in 1846, Lord John Russell paid the Earl of Dalhousie the rare compliment of asking him to remain at the Board of Trade, in order to carry out the regulations he had framed for the railway system. In 1847 he was appointed Governor-general of India, as successor to Lord Hardinge, and arrived in Calcutta, January 12, 1848—the youngest governor-general ever sent to that country. His Indian administration was not less splendid and successful in regard to the acquisition of territory than in the means he adopted for developing the resources of the country, and improving the administration of the East Indian government. Pegu and the Punjab were conquered; Nagpur, Oudh, Sattara, Jhansi, and Berar were annexed—altogether, four great kingdoms, besides a number of minor principalities, were added to the dominions of the Queen. Railways on a colossal scale were planned, and partly commenced; 4000 miles of electric telegraph were spread over India; 2000 miles of road between Calcutta and Peshawur were bridged and metalled; the Ganges Canal, the largest of the kind in the country, was opened; important works of irrigation all over India were planned and executed; and the department of public works was reorganised. Among other incidents of his beneficent administration may be mentioned his energetic action against suttee, thuggee, female infanticide, and the slave-trade; the organisation of the Legislative Council; the improved training of the civil service, which was opened to all natural-born subjects of the British crown, black or white; the successful development of trade, agriculture, forestry, mining; and a great reform in the postal service of India. In a minute which he drew up on resigning office, he reviewed with pardonable pride the events of his eight years' governor-generalship. His constitution had never been strong, and it gave way under the incessant labour and responsibility imposed upon him by his noble ambition. Meanwhile, honours had been showered upon him by his Queen and country with no sparing hand: in 1848 he was made a Knight of the Thistle; in 1849 he received the marquise, the thanks of both Houses of Parliament and of the East India Company for the 'zeal and ability' displayed in administering the resources of British India in the contest with the Sikhs; in 1852, on the death of Wellington, he was nominated by the then prime-minister, the Earl of Derby, to the office of Constable of Her Majesty's Castle of Dover and Lord Warden of the Cinque Ports. Dalhousie sailed from Calcutta in March 1856. On his arrival in England he was unable to take his seat in the House of Lords; and the remainder of his days was spent in much physical suffering and prostration of strength. On 19th December 1860 he died at Dalhousie Castle in his 48th year, leaving behind him a name that ranks among the highest in the roll of Indian viceroys for statesmanship, administrative vigour, and the faculty of inspiring confidence among the millions subjected to his sway. As he died without male issue, his title of marquise became extinct, the earldom of Dalhousie and other Scottish honours reverting to his cousin, Baron Pannure. His policy of annexation has been blamed for the

mutiny which broke out ere his death; but though, in Justin M'Carthy's words, 'he was a man of commanding energy and indomitable courage, with the intellect of a ruler of men and the spirit of a conqueror,' he was also of a most sensitive conscience, and entered on the Sikh and Burmese wars and embarked on a policy of annexation against his will. See the articles INDIA, OUDH, PEGU, PUNJAB, SIKHS; the Duke of Argyll's *India under Dalhousie and Canning* (1865); and Captain Lionel Trotter's *Dalhousie* in the 'Statesmen' series (1889).

Dallas, a town in the Spanish province of Almeria, at the foot of the Sierra de Gador, with a pop. of about 9500, who are employed chiefly in mining and smelting.

Dalkeith, a town of Midlothian, 6 miles SE. of Edinburgh, on a tongue of land between the North and South Esks. There is a large corn exchange (1855); of nearly a dozen places of worship the only old one is the parish church, collegiate once, of which Norman Macleod was for three years minister. The chief glory of the place is Dalkeith Palace, a seat of the Duke of Buccleuch (see SCOTT). Standing near the end of the High Street, in a beautiful park of 1035 acres, it is a Grecian edifice, built in 1700 by Sir John Vanbrugh for Monmouth's widowed duchess. The castle, its predecessor, was the seat first of the Grahams, and then of the Douglasses from the 14th century till 1642, when the ninth Earl of Morton sold it to the second Earl of Buccleuch. Dalkeith thus has memories of the Regent Morton (the 'Lion's Den' the castle was called in his day), of General Monk (1654-59), and of visits from James IV., James VI., Charles I., Prince Charles Edward, George IV., and Queen Victoria. It is the scene, too, of Moir's *Mansie Wauch*. Pop. (1841) 4831; (1881) 6931.

Dallas, capital of Dallas county, Texas, on Trinity River, 265 miles NNW. of Houston by rail. It is a flourishing place, with colleges for boys and girls, a medical institute, a number of flour-mills and grain-elevators, several foundries, and manufactures of woollens, soap, &c. Pop. (1880) 10,358.

Dallas, GEORGE MIFFLIN, an American diplomatist and statesman, was born in Philadelphia, July 10, 1792. His father, A. J. Dallas (1759-1817), was a distinguished lawyer of West Indian birth and Scottish descent, who filled with credit the positions of secretary of the treasury and acting-secretary of war under President Madison. The younger Dallas graduated at Princeton College in 1810. In 1813 he was admitted to the bar, and soon after entered the diplomatic service. In 1831 he was sent to the United States senate by the Pennsylvania legislature. He was United States minister to Russia from 1837 to 1839, and in 1844 was elected vice-president of the United States. In 1846 his casting-vote as president of the senate repealed the protective tariff of 1842, though he had previously been considered a Protectionist. His course on this question aroused much indignation in Pennsylvania. He was sent to Great Britain as United States minister at St James's from 1856 to 1861. He died at Philadelphia, December 31, 1864. His principal published writings were posthumous; they include a very readable and entertaining *Series of Letters from London* (1869), and a *Life of A. J. Dallas* (1871). His life was marked by assiduous devotion to official duties, which left him little leisure to look after his own private interests, and he lived and died a poor man.

Dalles. See COLUMBIA RIVER.

Dalling, LORD. See BULWER.

Dalmatia, a narrow strip of Austrian territory extending along the Adriatic Sea, and bounded on the N. by Croatia, on the E. by Bosnia, Herzegovina, and Montenegro. Area, 4940 sq. m.; pop. (1886) 510,372. The coast of Dalmatia and numerous adjacent islands is everywhere steep and rocky, and the chief towns, all of which are on the coast, are Zara, Sebenico, Lissa, Spalato, Brazza, Ragusa, and Cattaro. The country is mountainous, chiefly dry moorland, with numerous small lakes and rivers, most of which dry up in summer. The highest mountain is Orjen, near Cattaro, 6235 feet. The climate is uncertain; mean temperature about 60°; rainfall about 28 in. The Bora (q.v.) wind is much dreaded. About one-ninth of the land is arable, and produces wheat, barley, oats, maize, rye, and potatoes. Wine and olives are also produced. Nearly half of the land is in pasture, and wood occupies about a third. The islands are not very fertile, but supply good timber for shipbuilding. Cattle-rearing, seafaring, and the fisheries are the chief industries. The annual value of the exports and imports is £1,500,000. The exports consist principally of wine, oil, brandy, hides, wool, wax, honey, and fruits. Of the whole population, it is computed that about 55,000 are Italians, 1000 Albanians, 1000 Germans, 500 Jews, and the remainder consists of Southern Slavonians—chiefly Dalmatians and Morlaks. The Dalmatians are a fine race of men, bold and brave as seamen and soldiers, and formerly were the main support of the military power of Venice.

In ancient times Dalmatia was a considerable kingdom, and, after many unsuccessful attempts, was first subjugated by the Romans in the time of Augustus. On the fall of the Western Empire, Dalmatia, which had formed the most southern part of the province Illyricum, was captured by the Goths, from whom it was taken by the Avari (490), who in their turn yielded it to the Slavonians about 620. The state founded by the Slavonians continued until the beginning of the 11th century, when King Ladislavus of Hungary incorporated a part of Dalmatia with Croatia, while the other part, with the title of duchy, placed itself under the protection of the Venetian republic. The Turks afterwards made themselves masters of a small portion; and by the peace of Campo-Formio (1797), the Venetian part of Dalmatia, with Venice itself, became subject to Austrian rule. When Austria, in 1805, had ceded this part of Dalmatia to Napoleon, it was annexed to the kingdom of Italy; afterwards (1810) to Illyria. Since 1814 Dalmatia forms part of Austria; the commune of Spizza being added by the Congress of Berlin in 1878.

See Sir Gardner Wilkinson, *Dalmatia and Montenegro* (1848); Paton, *Highlands and Islands of the Adriatic* (1849); Wingfield, *Tour in Dalmatia* (1859); Yriarte, *Les Bords de l'Adriatique* (1878); Freeman, *Sketches from the Subject and Neighbouring Lands of Venice* (1881); Henri Cons, *La Province Romaine de Dalmatie* (1882); and Jackson, *Dalmatia, the Quarnaro, and Istria* (1887).

Dalmatian Dog, or CARRIAGE-DOG, a variety of dog closely resembling in size and shape the modern pointer. It is often kept in stables, becomes attached to the horses, and may be seen running after carriages. Its colour should be white with black spots not more than an inch in diameter regularly distributed over its body, including its ears and tail. Its origin is uncertain; the name Dalmatian is probably altogether misleading; and it is supposed that it may have been brought from India, where a very similar kind of dog exists.

Dalmatic (*Dalmatica*), the deacon's robe in the Roman Catholic Church. The most ancient form of the dalmatic is exhibited in the annexed

woodcut, after an early Christian painting on a wall in the catacombs at Rome. It was originally of linen, but it is now generally made of the same heavy silk as the Chasuble (q.v.).

Dalmatia.

Dalman, a city of Oudh, on the left bank of the Ganges, 60 miles NW. of Allahabad, with a magnificent Hindu temple. Pop. 5367.

Dalmellington, an Ayrshire village, near the river Doon, 15½ miles SE. of Ayr by rail. In its vicinity are many active collieries and ironworks. Pop. of the village alone (1881) 1437.

Dalriada ('the home of the descendants of Riada'), the ancient name of a territory in Ireland, comprehending what is now called 'the Route,' or the northern half of County Antrim. Its inhabitants were Scots of Gaelic race living in the midst of a Pictish population, and a number of them crossed over to Argyll in 498 and founded there another kingdom of Dalriada. More than twenty kings of this state are enumerated before Kenneth MacAlpin, who, about 843, united under one sceptre the Dalriads or Scots and the Picts, and thus became the first king of Alban, which about two centuries afterwards began to be known as Scotia or Scotland.

Dalry, a town of Ayrshire, on the Carnock, 23 miles SW. of Glasgow. Pop. (1851) 2706; (1881) 5010, this growth being due to the establishment of neighbouring ironworks in 1845.—For the skirmish at Dalry, near Tyndrum, see BRUCE.

Dalrymple, ALEXANDER, hydrographer, was a younger brother of Sir David Dalrymple, Lord Hailes, and was thus a member of an old and illustrious Scottish family (for its chief members, see STAIR and HAILES); he was born at New Hailes, near Edinburgh, 24th July 1737. At fifteen he sailed for Madras as writer in the East India Company's service, and after a few years' dreary work began to attract the notice of his superiors by his industry and intelligence. In 1759 he made a voyage of observation among the eastern islands, and after returning to Madras in 1762, was sent to open up the trade with Sulu, reaching Canton late in 1764. In 1775 he went to Madras as a member of council, but was recalled two years after on an unfounded charge of misconduct. He became hydrographer to the East India Company in 1779, and to the Admiralty in 1793, and died, three weeks after his summary dismissal from the latter office, 19th June 1808.

Dalrymple, SIR JAMES, was the second son of Sir James Dalrymple, baronet, afterwards first Viscount Stair. He was called to the Scottish bar in 1675, and ultimately became one of the chief clerks of the Court of Session, and a Nova Scotia baronet in 1698. He was a sound antiquary, and his work entitled *Collections concerning the Scottish History preceding 1153* (Edin. 1705) is still of value.

Dalton, JOHN, chemist and physicist, was born 6th September 1766, at Eaglesfield, near Cocker-mouth, in Cumberland, and was the son of a Quaker weaver. He received his early education at a

Quaker school in his native place, and, after 1781, in a boarding-school kept by a relative in Kendal, of which three years later he and a brother became the proprietors. Here his love of mathematical and physical studies was first developed. He wrote several mathematical essays, and in 1787 commenced a journal of meteorological observations, which he continued throughout his whole life, recording in all 200,000 observations. He collected butterflies, and gathered a great hortus siccus and herbarium. In 1793 he was appointed teacher of mathematics and the physical sciences in New College, Manchester: after the removal of the college to York in 1799, he supported himself in Manchester by private tuition. In 1803 he lectured at the Royal Institution. His *Meteorological Observations* (1793), dealing largely with auroras, contained the germs of many of his future discoveries. In 1794 he first described the phenomena of colour-blindness, observed by him in his own case and that of his brother, and often called Daltonism. In 1808-10 he published his *New System of Chemical Philosophy*, to which he added the first part of a second volume in 1827. In 1817 he was appointed president of the Manchester Philosophical Society. He was also a member of the Royal Society, and an associate of the Paris Academy, and of several other foreign societies. In 1833 he received a pension of £150, afterwards raised to £300. In the same year Dalton's friends and fellow-townsmen collected £2000, to raise a statue to his honour, which was executed by Chantrey, and placed at the entrance of the Royal Institution in Manchester. Oxford gave him its D.C.L., and Edinburgh, LL.D. He was twice a vice-president of the British Association. In 1837 he had a shock of paralysis, and he died, universally respected, at Manchester, July 27, 1844. His chief physical researches were on the constitution of mixed gases, on the force of steam, on the elasticity of vapours, and on the expansion of gases by heat. In chemistry, he distinguished himself by his development of the atomic theory, as also by his researches on the absorption of gases by water, on carbonic acid, carburetted hydrogen, &c. Dalton was unquestionably one of the greatest chemists that any country has produced. Profound, patient, and intuitive, he had precisely the faculties requisite for a great scientific discoverer. His atomic theory elevated chemistry into a science. In his habits, Dalton was simple; in manners, grave and reserved, but kindly, and distinguished by his truthfulness and integrity of character. He 'never found time' to marry. See the Lives of him by Dr Angus Smith (1836), Dr Henry (1854), and Lonsdale (1874); and the article ATOMIC THEORY.

Dalton-in-Furness, a town of Lancashire, 16 miles WNW. of Lancaster, communicating with the sea by a canal (3½ miles). It has extensive malting and ironworks; and the ruins of Furness Abbey (q.v.) are in the vicinity. Romney was a native. Pop. (1861) 2812; (1881) 13,339.

Daltonism. See COLOUR-BLINDNESS.

Dalyell, or DALZELL, THOMAS, a Scottish general famed for his zeal in the repression of the Covenanters, was born about 1599, the son of Thomas Dalyell of Binns, Linlithgowshire. Entering the army at an early age he was made a general major of foot by Charles II. in 1650; and excluded from Cromwell's Act of Grace, he entered the service of Russia and distinguished himself in the wars against the Tartars and Turks. At the request of Charles II. he was permitted to return home, and in 1666 was appointed commander-in-chief in Scotland with the view of repressing the Covenanters. On 28th November he defeated them at Rullion Green, in the Pentlands, and, in Burnet's

words, 'acting like Muscovite too grossly,' made his name a byword of terror. A very devoted royalist, he is said never to have shaved his beard after the execution of Charles I. He died 23d August 1685.

Dam. See WEIR, COFFERDAM.

Damages, in Law, are the pecuniary reparation due for loss or injury sustained by one person through the fault or negligence of another. Where a sum ascertained in amount is due, the action is one not properly for damages, but of debt. But where the sum is not ascertained, as where an injury has been done to a man's character or property, the action can in general only be for damages the amount of which the injured party estimates, and which is determined by the judgment of the court or verdict of a jury. When parties to a contract agree that if the contract be broken, a specified sum of money shall be paid, this sum is spoken of as liquidated damages, a sum agreed upon to save the trouble of ascertaining the actual damage done. Nominal damages are those given to a plaintiff who establishes his right, but has not shown that he has suffered actual loss. Exemplary or vindictive damages are given not only to compensate the injured party, but to punish the offender, as in actions for damages by fraud, seduction, and the like. Damages *ultra* are additional damages claimed by a plaintiff over and above those paid into court by a defendant. Every person is liable in damages for injuries caused by culpable neglect or ignorance. Professional persons are liable to make reparation of loss occasioned through their want of ordinary skill in their calling. Railway companies and steamboat owners are liable for injuries to person or property caused by the fault of themselves or their servants. The principal rules according to which damages are awarded are, that the damage is measured by the actual pecuniary loss, when ascertainable; that the injury suffered must be the immediate consequence of the faulty act or omission; and that all the parties concerned in committing a wrong are liable each for the full amount of damages to the injured party.

In the United States, the same general principles apply as in England. But the tendency of modern legislation, instead of restricting actions for damages to cases in which the restitution of property and the enforcement of rights are involved, is gradually being extended to cases involving civil injury arising from criminal negligence. This has been made necessary from the great powers granted corporations by law. Damages for the infringement of patents and copyrights may by act of congress be double or treble the verdict of a jury, at the discretion of the court. See COSTS, LIABILITY.

Daman, an outlying portion of the Punjab, extending along the right bank of the Indus, and as far back as the Suliman Mountains.

Daman, a Portuguese settlement and port in the province of Gujarat, on the Gulf of Cambay, 100 miles N. of Bombay. The settlement consists of Daman proper (22 sq. m.), and the *pargana* of Nagar Havili (60 sq. m.), to the east. Pop. (1881) of the former, 21,622; of the latter, 27,462, nearly all Hindus. The climate is generally healthy, the soil moist and fertile. The magnificent teak forests of Nagar Havili provide excellent timber for shipbuilding, for which Daman has some celebrity. The port, guarded by two forts, stands at the mouth of the Daman-Ganga, a deep, navigable stream, with a bar at its mouth, while outside is an excellent roadstead. Although the Portuguese have held Nagar Havili since 1780 only, Daman has been occupied by them since 1558. It formerly was noted for its weaving and dyeing, and exported its own fabrics to the

coast of Africa, besides large quantities of opium to China. The opium trade, however, has been stopped, and the chief industry, beyond the weaving of cotton cloth, and of bamboo mats and baskets, is now the deep-sea fishing, in which about 4500 men are engaged.

Daman. See HYRAX.

Daman-i-Koh ('skirts of the hills'), a tract of hilly country in Bengal, reserved for the Santals and other primitive races. Area, 1366 sq. m.; pop. (1881) 353,413.

Dam'araland, a territory in the west of South Africa, between Namaqualand and Ovampoland proper, extending from the Atlantic to about 19° 45' E. long. Behind the waterless coast region (100 miles) rises a mountain district, with peaks over 8500 feet above the sea; and farther inland stretch wide prairies. The mountains are rich in minerals, especially copper; vegetation is confined to their valleys, and to the prairie region, which in the north enjoys a fine rainfall. The produce of the interior consists of ivory, feathers, skins, &c. The Damaras, properly Herero, a Bantu (q.v.) stem, number about 80,000, of whom 50,000 live in the mountain district; they are nomads, and own large flocks and herds. The Hawkoin, or Hill Damaras, in the north-east, however, who are a much lower type, now speak Hottentot. The only harbour in this part of the coast is Walvisch Bay (q.v.), which properly belongs to Namaqualand; it was annexed to Cape Colony in 1884. In the same year the desert region along the coast was made a German protectorate.

Damascening, or DAMASKENING, is a name which is given (1) to the watered or striated structure seen in certain sword-blades and other weapons, and (2) to the ornamental incrustation with gold and silver of steel and iron surfaces. The term in both its applications originates from the city of Damascus, whence the crusaders brought into Europe swords and other weapons of remarkable strength, elasticity, and keenness of edge, the surfaces of which were beautifully striated with waved dark and light lines. The hilts of such weapons, and the whole surface of defensive armour from the same source were in many cases elaborately ornamented with incrustated gold, and hence one term came to be applied to the peculiar structure of the metal, and to its ornamental treatment. It is probable that even in the crusaders' times the making of the so-called Damascus blades and the art of damascening were Persian, and to this day they remain characteristic of that country, the practice having spread thence eastward into India, while the Persians still supply the Turks on the west with their best and most highly ornamented weapons. The production of a watered or damascened surface is illustrated by the manufacture of 'Damascus twist' barrels for sporting-guns. The metal for the barrels is prepared from rods of iron and steel, piled alternately and forged and welded together into a single solid rod of small section. Three of these composite rods are used in forming a barrel. They are separately twisted in contrary directions till each has the appearance of a fine threaded screw, then they are welded together into a solid ribbon, which in its turn is spirally wound and welded by the edges till the requisite length and bore of barrel are formed. The result of the intertwisting of fine laminae of steel and iron is a beautifully damascened surface which shows itself when the barrel has been treated with acid. The incrustation of arms, armour, and other objects of steel and iron with gold, and more rarely with silver, is very extensively practised in the North-west Provinces of India, as well as in Persia. In India it is known as Kufi work or Kufgari. The

design to be worked out is undercut in the metal, into this the gold or silver wire is laid, and the scarp edge is beaten down with a hammer, thus securing the wire in its position. Another method consists in scratching the surface, and beating into the scratched lines the gold or silver wire, after which the whole surface is burnished to remove the incisions.

Damascenus. See JOANNES DAMASCENUS.

Damascus is the capital of Syria, and the largest town in Western Asia. It is called by the natives *Dinashk es-Sham*, or simply *es-Sham*, the name which is generally applied to all Syria. The city stands $1\frac{1}{2}$ mile from the mouth of the gorge, through which the Barada, the *Chrysorrhoas* of the Greeks, forces its way into the plain; and it is now connected with Beyrout on the Mediterranean by an excellent French road about 70 miles long. The plain of Damascus, 500 sq. m. in area, is dotted by over a hundred towns and villages. It is bounded on the north-west by the Anti-Libanus range, on the south by the Black Mountains, beyond which are the hills of Bashan, and on the east by the marshes of the plain. Damascus is situated on the western side of the great plain at an elevation of 2260 feet above the level of the sea, and immediately to the north-west of the city the Anti-Libanus rises to a height of 3840 feet. This elevated part of the mountain, called *Jebel Kasyûn*, is crowned by the *Kubbet en-Nasr* ('Dome of Victory'). From the base of this dome the best view of Damascus is obtained. Its exquisite beauty, as seen from the mountain, is greatly enhanced by contrast. Towards the west there are the bare chocolate sahara and the storm-bleached, lime-streaked mountains. But the Barada, having forced its way through the mountain, spreads fan-like by seven rivers over the plain of Damascus, 'and everything lives whither the river cometh.' A beautiful green meadow, the joy of all orientals, extends almost from the mountain to the city; gardens, in which all the trees of the forest and the field blend their many shades, extend for many a mile and hold the desert at bay. From out this bower of soft green the city lifts to heaven its forest of minarets towering above pearly domes. The rivers of Damascus are the constant source of the city's perennial existence. According to tradition, Abraham on his westward march lingered by the crystal waters, and ruled the city in peace.

The seven canals by which water is drawn off from the central Barada are called rivers. The most important on the right side is *Nahar Abanias*. This is the river *Abana*, and it flowed through the fashionable west-end suburb in the palmy days of Damascus. The most important canal on the left side of the Barada is *Nahar Taura*—the *Pharpar* of 2 Kings, v. 12. Both rivers flowed through the residential parts of the city, and were largely used for bathing purposes.

The appearance of Damascus as viewed from the mountain resembles a tennis-racquet. The handle, which lies in a south-westerly direction, is the *Meidân*, a suburb which extends along the Mecca pilgrim-route for about a mile, and ends at the *Bawabat Alla* ('Gate of God'). The other part is concentrated on the rivers, and is inclosed within ancient walls and encompassed by luxuriant gardens which seem to surge around and over the pearl-coloured city like a sea. At the western side of the city within the walls stands the citadel. It is a large quadrangular structure about 300 yards long and 250 wide, with projecting towers, and surrounded by a moat. It was erected in 1219 by *Melik-el-Ashraf*, and has a massive appearance, but it is a good deal dilapidated. The palace stands outside the walls west of the citadel, and about 400

yards east of the citadel the Great Mosque towers above the city. The Mosque was erected by *Walid 'Abd-el-Melik* at the beginning of the 8th century on the site of the church of St John, just as that church had been erected by *Arcadius* about the beginning of the 5th century on the site of a pagan temple, which probably occupied the site of the ancient *Beit Rimmon*. The church was constructed from the splendid material of ancient temples, and the mosque is made up of the materials of ancient churches. The old walls and many of the columns of the church are still in position, and on a portal, older than Mohammedan or Christian times, is carved a cross, followed by the 13th verse of the 145th Psalm in Greek, from the Septuagint, with the abbreviation *Xc* added. The mosque is adorned by three minarets, one of which, called the minaret of Jesus, rises to a height of 250 feet, and on this minaret, according to Mohammedan tradition, Jesus will appear when he comes to judge the world. Near to the pulpit there is a richly gilded dome, beneath which the head of John the Baptist is said to rest, and in the court there is another dome which contains precious fragments of Kufic, Syriac, and other manuscripts. Damascus contains 70 other mosques, and more than 150 chapels for prayer and instruction. The churches and synagogues have no architectural pretensions, and their internal decorations are gorgeous but tawdry. The tomb of *Nûr ed-Dîn* is one of the ornaments of the city, and the walls of the best baths are decorated with beautiful *Kishani* tiles, and the floors with parian marble. The public cafés, though picturesque when lighted up, are dirty and sordid.

The religious communities occupy different quarters of Damascus. The Jewish quarter (*Harat-el-Yahoud*) lies to the south of the 'street called Straight,' which runs east and west for about a mile, with Roman gateways at either end. The course of the *Via Recta* can be traced by the columns *in situ*. The Christian quarter (*Harat-en-Nasara*) lies north of the street called Straight in the eastern part of the city, and the remainder of the city is occupied by Mohammedans. It is spoken of as *Harat-el-Islam*. The Christians are superior in physique, in education, in enterprise, in skill, in industry to their Mohammedan neighbours.

The different industries are also carried on in separate quarters. There is the silversmiths' bazaar, where rough but very effective personal ornaments are made; the saddlers' bazaar, where scarlet saddles and horse-trappings are gaily decorated with gold and silver thread; the shoemakers' bazaar, where red and yellow slippers of gondola-form and gorgeous top-boots are made; the Greek bazaar, where imitation 'Damascus blades' and 'antiques' newly made are offered to the unwary. The book bazaar (the Paternoster Row of the East), the cloth bazaar, the seed bazaar, the silk bazaar, and all the other trades and commodities, have their distinct locations. The narrow and badly paved streets of Damascus are dusty in summer and muddy in winter. On either side are the rows of arched niches which are the shops of the place. Each shopkeeper sits cross-legged in his *dukkân*, with his spices or Manchester goods piled up around him, awaiting customers, whom he serves with great stateliness of manner. Behind the mud walls and mean entrances there are splendid houses in Damascus. On entering, one is dazzled by the barbaric grandeur—white marble pavements, tessellated with coloured stone; snowy fountains where the constant music of falling water mingles with the cooing of doves from their nests in the lemon-trees or trellised vines; walls frescoed and decorated with mosaics and Persian tiles, and slabs inlaid with coloured pastes and

precious stones; arabesque ceilings set with Venetian mirrors, and adorned with blue and purple and gold—all that oriental art and lavish expenditure can do has been done to attract and charm the eye.

Great and steady progress is being made in Damascus in education, especially by the Christians; but the Jews and Mohammedans are also awaking to the necessity of a higher standard of civilisation. For many years the Irish Presbyterians have conducted successful educational establishments in the city and neighbouring villages as auxiliary to their mission work. The British Syrian schools have also an establishment, and the London Jews' Society.

One of the sights of Damascus is the Haj (q.v.). When it is starting for Mecca the whole city turns out to see the procession. For miles around there is a surging sea of human beings, dressed in the brightest and most striking colours. Circassians and Afghans, Kurds and Kalmuks, Turkomans and Tekkes, Bedawin from the desert, and shepherds from the steppes, and all the heterogeneous tribes and peoples of the East, are represented in that brilliant procession. Damascus is also one of the meeting-places between the East and West. Enormous caravans of camels pass to and fro between Bagdad and Damascus, exchanging the dates and tobacco and spices and carpets of the East for the produce of the looms and workshops of Europe. The chief exports are grain, flour, native cotton and silk manufactures, wool, apricot paste and stones, raisins, and liquorice-root; the imports include textiles, indigo, tobacco, coffee, sugar, and leather. In 1887 the total exports were valued at £341,294, and the imports at £398,423, more than half of the latter being British. In 1889 gas and tramways were introduced into the city. Pop. about 150,000, of whom 20,000 are Christians of various sects (32,000 before the great massacre of July 1860); 6000 are Jews; and the remainder Mohammedans.

Damask. This name, long given to certain fabrics with ornamental patterns, appears to have originated through Damascus having become, as early as the 12th century, so celebrated for its figured silks that they were sought for everywhere. The term damask is now applied to stuffs made for table-covers, window curtains, and furniture coverings, with floral, scroll, heraldic, or partly geometrical patterns woven in the loom, but not to printed designs. There are silk, woollen, linen, and cotton damasks. Some are of two materials, usually dyed of different colours, such as silk and linen, or silk and wool, while many old damasks are of silk and gold. There are other figured textiles more or less resembling damask, such as Brocade (q.v.) and figured Velvet (q.v.), but on these the pattern is generally, at least slightly, raised, while in damask the surface is flat, and the pattern is distinct on both sides of the cloth. The structure of damask, like diaper, is merely a variety of twilling. It is by the order in which the warp threads are raised and depressed for the interweaving with the weft that the pattern is produced; the weft, as a rule, intersecting the warp from every fourth up to every eighth thread. This is accomplished by a Jacquard apparatus attached to the loom. The pattern is first painted on a specially prepared paper, and then 'read off' and perforated on cards by a cutting machine made for the purpose, each card being made to control the arrangement for one shot or weft thread. These cards, which may be from 200 to 2000 in number, are laced into an endless chain, and made to revolve on a cylinder forming part of the apparatus. The holes in the cards correspond to a certain number of cross 'needles,' into which are looped upright wires

terminating in hooks for lifting the warp threads. The mechanism for raising such of these wires, and with them the warp threads as are required for each throw of the shuttle, is explained under JACQUARD-LOOM. It requires four Jacquard-machines to complete some patterns of damask, and a greater number if the design is exceptionally elaborate.

Table-linen damask is perhaps the kind most largely made. In Great Britain, the principal seats of this manufacture are Dunfermline in Scotland, Belfast in Ireland, and Barnsley in Yorkshire. At some of the linen damask mills in England and Scotland, coloured union damask, of wool and linen, is also made on a large scale. Cotton damasks, both dyed and undyed, are woven extensively at Manchester and its neighbourhood, as well as at Glasgow and Paisley. The mills where all-wool damasks are chiefly manufactured are situated at or near Halifax and Bradford, where a new kind, consisting of mohair, or of mohair and silk, has been recently fabricated. Silk damasks are principally made in the neighbourhood of London. Since 1860, largely through the labours of Dr Bock of Aix-la-Chapelle, one or two very interesting collections of European damasks and other figured stuffs, ranging in date from the 13th to the 16th century, have been made. A catalogue with some illustrations of the specimens in the South Kensington Museum was prepared some years ago by the Rev. Dr Daniel Rock. Since then some remarkable examples have been added, and the authorities of that institution are now publishing large coloured illustrations of these. The original pieces, even though many of them are much faded, give a vivid idea of the beauty of the products of the looms of Sicily, of Florence, Venice, Lucca, and Genoa, and of some Spanish towns, during the middle ages. The materials of which they are made are silk alone, silk and gold, silk and linen, and silk and cotton. When flowers or animals are represented on these damasks, they are conventionally, not realistically, treated, and the designs of most of them are so appropriate and effective, that even the chromolithographs of them are of great value not only to the textile designer, but to students of every branch of decorative art.

Damasus, the name of two popes of Rome.—**DAMASUS I.** was born in 306, probably at Rome, became archdeacon of the Roman Church in 355, and pope in 366. The party of Ursinus, the rival of Damasus, were overpowered after a sanguinary struggle of three days in the streets of Rome, and afterwards in the Basilica Liberiana (S. Maria Maggiore), from which 137 corpses were carried out in one day, the 25th October 366. The Emperor Valentinian I. decided in favour of Damasus, and twelve years later, the schism still continuing, an edict of Gratian (378) made him the judge in the case of all the clergy of the hostile party who still lived in Rome. He was a zealous opponent of the Arians, and condemned the Illyrian bishops Ursacius and Valens at a synod which he held at Rome in 368, and Auxentius, Bishop of Milan, at a second synod there in 370. Damasus induced his friend Jerome to undertake the revision of the *Italia* (in 383 and 384), which led him to the preparation of the Vulgate version; and he did much for the preservation and adornment of the Roman catacombs. He died in 384, and was canonised. His festival falls on the 11th December. The writings of Damasus, which are chiefly letters and epigrams, were published at Rome in 1638 (new editions, Rome, 1754, and Paris, 1840). See Langen, *Geschichte der römischen Kirche* (vol. i. Bonn, 1881), and Rade, *Damasus, Bischof von Rom* (Freiburg, 1882).—**DAMASUS II.**, previously Poppo, Bishop of Brixen, was elected pope in 1048, through the influ-

ence of the Emperor Henry III., and died twenty-three days after his accession.

Dambula, or **DAMBUL**, a vast Buddhist rock-temple in Ceylon, 40 miles N. of Kandy, containing, among a profusion of carvings, figures of Buddha of extraordinary magnitude. See **CEYLON**.

Dame (Lat. *domina*, 'a mistress'), a title of honour which long distinguished high-born ladies from the wives of citizens and of the commonalty in general, and which still is the accurate title of a knight's wife (see also **BARONET**). In the age of chivalry, it was customary even for a queen to be so called by her chosen knight ('the dame of his heart, of his thoughts,' &c.). In consequence of the greater courtesy shown towards women of higher rank, arose the custom of prefixing the word *ma* to *dame*, as a special proof of veneration and homage. Hence, too, the Virgin-mother was called in France *Notre Dame* ('Our Lady', as if no single Christian could exclusively claim the privilege of serving her with the homage of his heart). The daughters of the king of France, as soon as they came into the world, were called *Madame*; and this was also the sole title of the wife of the king's eldest brother. In England, the word *Dame*, though not much used, is now applied to married women of all classes; but has recently acquired a special significance in connection with the Primrose League (q.v.). It is also applied specially to the mistress of a small elementary school, especially if elderly and ignorant. *Madame* is shortened into *Madam*, a usual term of address for ladies in general, but still also a word of honour, applicable, in particular cases, to majesty itself. Thus Tennyson in dedicating his poems to Queen Victoria, speaks as a chivalrous troubadour might have done—

Take, *Madam*, this poor book of song.

Dame's Violet (*Hesperis*), a genus of Crucifere, closely allied to stock and wallflower; natives

chiefly of the middle and south of Europe, and temperate Asia. One only, the Common Dame's Violet or Rocket (*H. matronalis*), occurs wild in Britain as a garden escape. The usually lilac-coloured flowers are scentless by day, but very fragrant at night, on which account this plant is cultivated in flower-pots by German ladies. The custom appears to have been an old English one also, and from it the plant derives its technical name. The Night-scented Rocket (*H. tristis*) is also a favourite flower in Germany.

There are many florist's varieties ranging on each side of the familiar lilac tint to purple or white, often also variegated, and single or double.

Damiani, **PIETRO**, a great Italian ecclesiastic of the 11th century, was born in 1007 at Ravenna,

herded swine in his boyhood, but rose by his learning and devotion to the interests of the Church to be cardinal and Bishop of Ostia (1057). He supported with vigour the ecclesiastical policy of Hildebrand (afterwards Gregory VII.), without sharing his arrogance and ambition, and was employed in many important missions. He died at Faenza in 1072. His letters, speeches, and other writings were collected by Cardinal Cajetan, and often reprinted (best ed. 4 vols. Ven. 1743). See the *Life* by Neukirch (Gött. 1875).

Damianus, **St.** See **COSMAS**.

Damien, **FATHER**, a young Belgian priest who in 1873 devoted himself to the awful duties of spiritual guide to the lepers confined to the Hawaiian island of Molokai. Sent on a mission to Honolulu, where he heard from the bishop the neglected state of the lepers, some 700 or 800 in number, who lived on that small island, he volunteered to establish himself amongst them; and from 1877 onwards became physician of their souls and bodies, their magistrate, teacher, carpenter, gardener, cook, and even gravedigger at need. For long he worked on single-handed at his noble labours, but was ultimately joined by another priest. For twelve years he escaped all contagion of the fatal disease, though in constant contact with the sick and dying; but in 1885 the malady appeared in him, and though his doom was sealed, he continued unabated his heroic labours. His family name was Damien de Veuster. His story is alluded to in Fronde's *Oceana*.

Damiens, **ROBERT FRANÇOIS**, the would-be murderer of Louis XV., was born in 1714 near Arras. Already known in his youth as *Robert le Diable*, he was by turns a soldier and a servant in Paris; in 1756 he was forced for a robbery to flee to Belgium, but ventured to return to Paris about the end of the year. Already he had formed the plan to murder the king, either, as he himself alleged, on account of his conduct towards the parliament, or because, as was generally asserted, he was instigated by the Jesuits. On 4th January 1757 he went to Versailles, next day followed the king and his courtiers about everywhere, and about six o'clock at night, when the king was entering his carriage to leave Trianon, managed to stab him. Damiens was seized before he could finish the deed, and was nearly three months later adjudged by the parliament to a horrible death. The hand which had attempted the murder was burned at a slow fire; the fleshy parts of his body were then torn off by pincers, and melted resin and oil poured into the wounds; finally, he was torn to pieces by four horses. The fragments of his body were burned, the house in which he was born pulled down, and his family banished from France for ever.

Damietta (Arab. *Dinayut*), a town of Lower Egypt, situated on the right bank of the chief eastern mouth of the Nile, about 8 miles from its mouth in the Mediterranean. It is irregularly but well built, and has some handsome mosques and marble baths, and of course several bazaars. Its commerce has been much injured by the prosperity of Alexandria, but it still carries on a considerable trade in exporting rice, fish (from Lake Menzala), coffee, and dates; and imports charcoal, soap, and manufactured goods. It is the terminus of a branch-railway from Cairo. The cambric (*kasab*) known as *dinuty* received its name from Damietta, where it was first manufactured, but it is so no longer (Lane-Poole, *Art of the Saracens*), and the leather-work for which it was famous has also declined. A bar at the mouth of the river prevents vessels of more than fifty or sixty tons burden from ascending to the city. Pop. about 30,000. The existing town was erected after 1251, but, prior to that, a city of

Common Dame's Violet (*Hesperis matronalis*).

the same name (more anciently Tamiáthis) stood more to the south. It was strongly fortified by the Saracens, and formed on that side the bulwark of Egypt against the early crusaders, who, however, succeeded in capturing it more than once. It was razed, and rebuilt farther inland on the site it now occupies, by the Mamluk sultan Beybars.

Dammar, or **DAMMAR PINE** (*Agathis, Dammar*), a genus of Coniferae, of the family Araucariaceae, distinguished from *Araucaria* by its laterally winged seeds not being adherent to the carpellary leaf. There are four species, all oriental

Branch of Dammar Pine.

or Australasian, of which the most familiar is *A. (Dammar) orientalis* or *alba* of the lower mountain-regions of the Malay Archipelago, Borneo, and the Philippines, a lofty tree with stout, leathery, lanceolate leaves. The timber is light, but the tree is chiefly valuable for its extraordinary abundance of resin, which is not only obtained in quantity from incisions which are best made in the large knot-like prominences of the lower part of the stem and the root, but which naturally exudes so freely as to form large lumps underground, and foot-long icicles or stalactite-like masses hanging from the branches. According to Miguel it even drips from the branches in Sumatra in such quantity as often to form incrustations and rock-like masses on the banks of streams. At first semifluid and of pleasant balsamic odour, it soon hardens into an inodorous transparent mass, of no great hardness, but of glossy appearance and conchoidal fracture. It is soluble in cold ether, and at all temperatures in ethereal and fatty oils; but not entirely in boiling alcohol. It is of great value in the preparation of transparent and rapidly drying varnishes. The name signifies in Malay, 'light.' The Kauri Pine (q.v.) of New Zealand is *A. australis*. *D. ovata* of New Caledonia has also similar properties.

The same name is applied in commerce to the resin of other and unrelated trees. Thus the dammar of shipyards is derived from a species of *Canarium*, an Amyridaceae tree, while Black Dammar is a kind of pitch derived from the allied *Marignia*. *Shorea robusta*, a dipteraceae tree, yields pitch and resin used in Indian dockyards, and sometimes also called dammar. Dammar is also occasionally confused with kinds of copal; thus the resin of *Vateria indica* (Dipteraceae) is sometimes known as Dammar or Piny Dammar. It is the source of the Piny Varnish of India. See COPAL.

Damnatory Clauses. See ATHANASIAN CREED.

Damocles, one of the courtiers and flatterers of the elder Dionysius, tyrant of Syracuse. Cicero tells how Damocles, having extolled in the highest terms the grandeur and happiness of royalty, was reproved by Dionysius in a singular manner. The sycophant was seated at a table, richly spread and

surrounded by all the furniture of royalty, but in the midst of his luxurious banquet, on looking upwards, he saw a keen-edged sword suspended over his head by a single horse-hair—a sight that at once altered his views of the felicity of kings.

Damodar, a river of Bengal, rises in the Chutia Nagpur watershed, and after a south-easterly course of 350 miles, enters the Hoogly from the right. The valley of the Damodar abounds in coal and iron; and some 40,000 tons of coal are brought down yearly in native boats, strengthened to resist the strain caused by frequent grounding on sand-banks.

Damoh, a town of India, in the Jabalpur division of the Central Provinces, 50 miles E. of Sagar, with 8665 inhabitants.—The district of Damoh has an area of 2799 sq. m., and a pop. (1881) of 312,957.

Damon and Pythias (more correctly Phintias), two noble Pythagoreans of Syracuse, remembered as the models of faithful friendship. Pythias having been condemned to death by the elder Dionysius, the tyrant of Syracuse, begged to be allowed to go home, for the purpose of arranging his domestic affairs, Damon pledging his own life for the reappearance of his friend at the time appointed for his doom. Dionysius consented, and Pythias returned just in time to save Damon from death. Struck by so noble an example of mutual affection, the tyrant pardoned Pythias, and desired to be admitted into their sacred fellowship.

Damper, a door or valve which, by sliding, rising and falling, turning on a hinge, or otherwise, diminishes the aperture of a chimney or air-flue; this lessens the quantity of air that can pass through a furnace or other fire, and thus 'damps' or checks the combustion.—The damper of a piano-forte is that part of the mechanism which, after a key is struck, and the finger is lifted up from the key, immediately checks or stops the vibration of the string (see PIANO).—Damper is also the name given in Australia to a simple kind of unleavened bread formed of wheat-flour. It is made while travelling in the bush, and baked among the ashes of a fire often kindled for the purpose.

Dampier, the name of several places in Australasia: (1) Dampier Archipelago, a cluster of about twenty small rocky islands off the NW. coast of Australia, in 21° S. lat., and 117° E. long., divided by the Mermaid Strait in two groups; in the eastern is Rosemary, the largest island.—(2) Dampier Island, off the NE. coast of New Guinea, with a volcano about 5250 feet high.—(3) Dampier's Land, a peninsula of Western Australia, fertile and well watered, lying between King Sound and the Indian Ocean.—(4) Dampier Strait, between New Guinea and the archipelago of New Britain, forming, with Goschen Strait to the SE., the shortest route from Eastern Australia to China by some 300 miles.—(5) Dampier Strait, separating the island of Waygiou from the NW. extremity of New Guinea, the safest and easiest passage between the Indian and Pacific oceans.

Dampier, WILLIAM, a celebrated English navigator and hydrographer, was born near Yeovil in Somersetshire in 1652. He went early to sea, saw much hard service, and gained a great knowledge of hydrography in voyages to Newfoundland, Bantam, Jamaica, and the Bay of Campeachy. After spending a few years among the lawless log-wood-cutters on the coast of Yucatan, where honest trade was pleasantly varied with private piracy, he joined in 1679 a regular party of buccaneers who crossed the Isthmus of Darien, sacked Santa Marta, and ravaged the coast as far south as the island of Juan Fernandez. In 1683 he engaged in another

buccaneering expedition, in which he coasted along the shores of Chili, Peru, and Mexico, sailing thence across the Pacific, and touching at the Philippine Islands, China, and New Holland. Put ashore on Nicobar Islands, May 1688, after a dispute with his comrades, he made his way by sheer seamanship in a native canoe to Atcheen, and after two years' trading in the neighbouring seas, made his way to England (1691), where he published his vigorous and interesting *Voyage round the World* (1697). He was afterwards deputed by government to conduct a voyage of discovery to the South Seas, in which he explored the west and north-west coasts of Australia, also the coasts of New Guinea and New Britain, giving his name to the Dampier Archipelago and Strait. On the return voyage his vessel was wrecked off Ascension, and Dampier with his crew lived on turtles and goats on that island for over two months, until relieved. The old buccaneer was more skilful as a pilot than successful as a commander, and his overbearing cruelty to his lieutenant led to himself being court-martialled. Yet soon after he was again appointed to the command of two vessels in a privateering expedition to the South Seas. He was as unfortunate as before. According to an account published by Fummell, one of his sailors, Dampier was guilty not merely of drunkenness and brutality, but even of cowardice, which at least is hard to believe of an old buccaneer. The master of one of his two vessels was that Alexander Selkirk who was marooned at Juan Fernandez, and was yet to be made immortal as Robinson Crusoe. Dampier returned home at the close of 1707, poor and broken, nor did his angry *Vindication* re-establish his reputation. Next year he sailed again to the South Seas as pilot to a privateer, which rescued Selkirk, and returned in 1711 after a prosperous voyage. Dampier died in London early in March 1715.

Damping off, in Horticulture, the death of plants from excess of moisture in the soil and atmosphere. Young seedlings in stoves and hotbeds are particularly liable to it. Although the cause is sufficiently obvious, prevention is not always easy; not only because some plants are very sensitive as to moisture, but also because the necessity of keeping sashes closed on account of temperature often stands in the way of the ventilation which would otherwise be desirable, and it is when a moist atmosphere stagnates around them, and the temperature is not very low, that plants are most liable to damp off.

Damson, a rather small oval-fruited variety of the common plum, much esteemed for preserving, and not wholly unfit for dessert. The tree grows to a considerable height, but has a bushy, sloe-like appearance. It is extremely fruitful. There are many sub-varieties, with fruit of different colours, dark purple, bluish, black, yellow, &c. Damsons are produced in great quantities in some parts of England. Damson pies and damson cheese—made somewhat in the manner of fig-cake—are well known. The name is a corruption of *Damascene*, from Damascus.—The Mountain Damson or Bitter Damson of the West Indies is the *Simaruba* (q.v.).

Dana, CHARLES ANDERSON, an American man of letters, was born at Hinsdale, New Hampshire, 8th August 1819, spent two years at Harvard, and was a member of the Brook Farm (q.v.) community. From 1848 to 1862 he was the managing editor of the *New York Tribune*, which he was largely instrumental in making the leading organ of the party opposed to the extension of slavery to new territories; and from 1863 to the close of the war he was assistant-secretary of war. In 1867 he founded the *New York Sun*, and commenced the

successful management of that journal on democratic lines. He has published several translations and anthologies, collaborated in a *Life of Grant* (1868), and, along with George Ripley, who had been an associate at Brook Farm, planned and edited the *New American Cyclopædia* (1857-63), and its revised edition, the *American Cyclopædia* (1873-76), both in 16 vols. See *ENCYCLOPÆDIA*.

Dana, JAMES DWIGHT, an American mineralogist and geologist, was born at Utica, New York, 12th February 1813. He graduated at Yale College in 1833, and was sent out in 1838 as a scientific observer in the United States exploring expedition, under Wilkes, visiting the Antarctic and Pacific. During the course of this expedition Dana's ship was wrecked. He was afterwards associated with his father-in-law, the elder Silliman, in the editorship of the *American Journal of Science*. In 1846 he was elected professor of Natural History and Geology in Yale College. Among his works are a *System of Mineralogy* (1837), a *Manual of Mineralogy* (1848), two treatises on Corals, a *Text-book of Geology* (1864), and many highly valued reports on geological, mineralogical, and zoological subjects. His principal text-books have been repeatedly enlarged and revised. Dr Dana's labours have gained him world-wide distinction, and he has been elected to membership in most of the prominent scientific societies of Europe and America.

Dana, RICHARD HENRY, an American poet and prose writer, was born at Cambridge, Massachusetts, 15th November 1787. He was educated at Harvard College, and was admitted to the bar at Boston in 1811. In 1818 he became associate editor of the *North American Review*, to which he contributed largely. Some of his poems, such as *The Dying Raven* (1821), and *The Buccaneer* (1827), were warmly praised by critics on both sides of the Atlantic. The American public, however, received them coldly, partly because it was not at that time educated up to the standard of Dana's work, but chiefly because that work, with all its literary merits, such as learning, neatness of execution, and precision in verbal expression, lacked the elements which most appeal to the popular feelings. Dana's best literary work was done in the field of criticism. His abilities as a critic were very decided; and though many of his best efforts were not duly appreciated in his day, they did much to educate and elevate the literary taste of New England. A collection of his prose and verse appeared in 1833. He was for a time in 1821-22 connected with *The Idle Man*, a meritorious though ill-supported literary periodical. He died at Boston, 2d February 1879.—His son, RICHARD H. DANA, author and lawyer, was born 1st August 1815, and graduated at Harvard College in 1837. During an interval in his collegiate career, occasioned in part by a troublesome affection of the eyes, he shipped as a common sailor, and made a voyage to California and back. This voyage he described in *Two Years before the Mast* (1840), the best book of the kind in the language; in 1840 he was admitted to the Massachusetts bar. As a lawyer he attained great distinction, especially in the department of maritime law. Among his works are *The Seaman's Friend* (1841) and *To Cuba and Back* (1859). He also published an edition of Wheaton's *International Law*, and was prominent as a Free-soiler and Republican politician. In 1879 he was nominated to the position of minister to England, but after a long contest the senate failed to confirm the appointment. He died in Rome, 7th January 1882.

Danaë, the daughter of Acrisius, king of Argos, herself the great-grandson of Danaus. An oracle had announced that she would one day give birth to a son, who should kill his grandfather. Acrisius,

for safety's sake, shut her up in a dungeon, where, nevertheless, she was visited by Zeus in a shower of gold, and so became the mother of Perseus. Acrisius next put both the mother and child into a chest, and exposed them on the sea. The chest, however, drifted ashore on the island of Seriphos, and Danaë and her child were saved. She remained in the island until Perseus (q.v.) had grown up and become a hero famous for his exploits; afterwards she accompanied him to Argos. On his arrival, Acrisius fled, but was subsequently slain accidentally by Perseus at Larissa.

Danakil (singular *Dankali*), the Arabic and now general name for the numerous nomad and fisher tribes inhabiting the coast of north-east Africa, from Massowah south to Tajurrah Bay, and from there south-west to Shoa. They belong to the Ethiopic Hamites, and are well built and slender, with features indicating an intermixture of Arab blood. In a country of waterless plains, they are generally nomads, living partly by caravan traffic and the slave-trade, but mostly on the milk of their flocks. For the language, see Isenberg's *Vocabulary* (Lond. 1840); see also Scaramucci and Giglioli, *Notizie sui Danachili* (1884).

Danaüs, in Greek Mythology, the son of Belus and twin-brother of Ægyptus, originally ruler of Libya. Fearing his brother, he fled to Argos, with his fifty daughters, the Danaides, and here he was chosen king, in place of Gelanor. The fifty sons of Ægyptus followed him, and under the pretence of friendship, sought the hand of his daughters in marriage. Danaüs consented, but on the bridal night he gave his daughters each a dagger, and urged them to murder their bridegrooms in revenge for the treatment he had received from Ægyptus. All did so, except one, Hypermnestra, who allowed her husband, Lynceus, to escape. The poets tell how in the under-world the Danaides were compelled, as a punishment for their crimes, to pour water for ever into a vessel full of holes. From Danaüs, the Argives were called Danai.

Danbury, one of the capitals of Fairfield county, Connecticut, 69 miles NNE. of New York; has a sewing-machine factory, and over a dozen manufactories of hats, employing a capital of \$1,500,000. Pop. (1880) about 8000; of the township, 11,666.

Danby, FRANCIS, A.R.A., landscape-painter, was born near Wexford, Ireland, 16th November 1793. In 1812 he began to exhibit in Dublin; in 1813, with O'Connor and George Petrie, afterwards president of the Hibernian Academy, he started for London, but at Bristol the means of the party were exhausted, and Danby resolved to settle in that city, where he resided till 1824. His 'Upas Tree,' a large and impressive work, now in the South Kensington Museum, was exhibited in the British Institution (1820); his 'Disappointed Love,' in the Academy (1821), as also his 'Delivery of the Israelites out of Egypt' (1825), which gained him his election as an associate. In 1828 his 'Opening of the Sixth Seal' won a premium of £200 at the British Institution; in the following year two other important subjects from the Apocalypse appeared in the Academy. At this time a disagreement arose between the artist and the Academy, which, along with other reasons, led to his leaving England. For eleven years he resided on the Continent, mainly in Switzerland, painting little, and amusing himself with boating. On his return to England, he took up his residence at Exmouth, and contributed very regularly to the Academy till his death on 9th February 1861. His 'Fisherman's House, Sunset' (1846), is now in the National Gallery. His works, of which several have been engraved, are distinguished by

imagination and poetic feeling. His three sons, John, Thomas, and James Francis, were all landscape-painters. The last named was born at Bristol in 1816, and died in London, 22d October 1875.

Danby, LORD. See LEEDS, DUKE OF.

Dance, GEORGE (1700-68), architect, designed the Mansion House (1739) and many other London buildings.—His son, GEORGE DANCE, the younger (1741-1825), rebuilt Newgate (1770-83), and was one of the original Royal Academicians.

Dance of Death (Lat. *Chorea Machabæorum*, Fr. *La Danse Macabre*), a name given to a certain class of allegorical representations, illustrative of the universal power of death, and dating from the 14th century. When the introduction of Christianity first banished the ancient Germanic conception of a future state, a new description of death-mythology arose, partly out of biblical sources, partly out of the popular character itself, wherein the Last Enemy was represented under simple and majestic images, such as that of a husbandman watering the ground with blood, ploughing it with swords, sowing it with corpses, rooting out weeds, plucking up flowers, or felling trees; or of a monarch assembling his armies, making war, taking prisoners, inviting his subjects to a festival, or citing them to judgment. But with a gradual change in national manners came a change in the mode of treating the subject, and it was associated with everyday images, such as the confessional, chess-playing, and above all, with the adjuncts of a festival—viz. music and dancing. This tendency to familiarise the theme increased during the confusion and turmoil of the 14th century, when the national mind alternated between fits of devotion and license, or blended both elements in satire and humour. Such a mood as this naturally occupied itself with personifying Death, and adopted by preference the most startling and grotesque images it could find—that of a musician playing to dancing-men, or a dancer leading them on; and as the dance and the drama were then intimately connected, and employed on religious occasions, this particular idea soon assumed a dramatic form.

This drama was most simply constructed, consisting of short dialogues between Death and four-and-twenty or more followers, and was undoubtedly enacted in or near churches by religious orders in Germany during the 14th century, and at a rather later period in France. It would appear that the seven brothers, whose martyrdom is recorded in the 7th chapter of the 2d Book of Maccabees, either played an important part in the drama, or the first representation, which took place at Paris in the Monastery of the Innocents, fell upon their festival, and hence the origin of the ancient name, *Chorea Machabæorum*, or *La Danse Macabre*. As early as 1400, the dramatic poem was imitated in Spain, and appears there in seventy-nine strophes of eight lines each (*La Dança General de los Muertos*), but it did not spread; while the French, having a love for pictorial representation, very early affixed an illustration to each strophe, and in 1425 painted the whole series on the churchyard wall of the Monastery of the Innocents, where the Dance of Death was habitually enacted. We find the subject treated in painting, sculpture, and tapestry, in the churches of Anjou, Amiens, Angers, Rouen, to say nothing of the numerous woodcuts and accompanying letter-press which succeeded the invention of printing. From Paris, both poem and pictures were transplanted to London (1430), Salisbury (about 1460), Wortley Hall in Gloucestershire, Hexham, &c.

But nowhere was the subject so variously and strikingly treated as in Germany. A picture in one of the chapels of the Marienkirche, at Lübeck,

still, in spite of repeated re-paintings, bearing the unmistakable impress of the 14th century, exhibits the very simplest form of the drama, and has some Low-German verses attached to it. Here we see twenty-four figures, partly clerical, partly lay, arranged in a descending scale, from the pope himself down to a little child, and between each of them a dancing figure of Death, not in the form of a skeleton, but a shrivelled corpse, the whole being linked in one chain, and dancing to the music of another Death. This representation is almost the same as a very ancient one at La Chaise-Dieu, in Auvergne, and points to the identity of the original dramatic spectacle in both countries.

The celebrated Dance of Death on the cloister walls of the Klingenthal, a convent in Basel, though painted probably not later than 1312, exhibited a departure from the simplest form—the number of persons exceeding the original twenty-four, and the chain being broken up into separate couples. But both alike are only to be regarded as scenes from a drama, and cannot, therefore, be justly compared with a painting in the Pisan Campo Santo, the 'Triumph of Death,' ascribed to Andrea Orcagna. And the acted drama enduring till the 15th century, we find that while there were varieties in the paintings, the poem, which was the most important feature, remained almost unchanged.

About the middle of the 15th century, however, the drama being altogether laid aside, the pictures became the main point of interest, the verses merely subsidiary. Accordingly, we find from this time the same pictures repeated in different places, with different verses, or no verses at all, till at length both verses and pictures entirely change their original character. The Dance of Death being transferred from the quiet convent walls into public places, gave a new impulse to popular art. Duke George of Saxony had, in 1534, the front of his Dresden castle ornamented with a life-size bas-relief of the subject, and other representations are to be found at Strasburg and Bern. There was a Dance of Death painted round the cloister of old St Paul's in London, in the reign of Henry VI.; and there is a sculptured one at Rouen, in the cemetery of St Maclou. But Holbein has the credit of availing himself most effectively of the original design, and giving it a new and more artistic character. Departing from the idea of a dance, he illustrated the subject by fifty-three distinct sketches for engravings, which he called 'Imagines Mortis.' The originals of these are at St Petersburg, and impressions of them have been frequently repeated under different names.

See Peignot's *Recherches sur les Danses des Morts* (1826); Massman's *Baseler Todtentänze* (1847); and Douce's *Dance of Death* (1833).

Dancetté, one of the lines of partition in Heraldry, which differs from Indented (q.v.) in the greater width and depth of the indentations. A fess dancetté has but three indentations, as in the subjoined figure.

Fess Dancetté.

Dancing, a form of exercise or amusement in which one or more persons make a series of more or less graceful movements with measured steps in accord with music. In its earliest forms among simple races it is a mode of outward expression for strong emotions of joy and sorrow, love and rage, and even for the most solemn and impassioned religious feelings; in more civilised strata of human society it becomes a mere frivolous amusement with no high signification whatever. Dancing corresponds to a universal primitive instinct in man.

It is still practised by the South Sea Islanders, the forest Indians of Brazil, the Zulus, the negroes of Central Africa, and the native Australians, exactly as it was in the earlier stages of every civilised modern race. Many of the rude courting dances of modern savages, like the native Australian *corro-boree*, are themselves refinements of more ancient dances, in the survivals of which we can guess at their original grossness and obscenity. Ferocious war-dances were constantly practised by savage warriors, as the North American Indian braves, who worked themselves up into frantic mechanical intoxication capable of carrying them irresistibly on to victory. The Zulu war-dance is still a noble exercise for warriors, like the Pyrrhic dance of the ancient Spartans; and the dancing and spinning dervishes in the East, who work themselves into spasms of physical excitement, are still highly esteemed for devoutness and piety. Into savage dancing, moreover, the idea of magic always enters. Thus the Mandan Indians dance buffalo to bring game when supplies of food are low, the rain-doctors of Central Africa dance mystic dances to bring down rain, and the wives of Gold Coast negroes dance a battle-dance to give their absent husbands courage in the battle. Everywhere in ancient religions is dancing one of the chief acts of worship. Religious processions went with song and dance to the Egyptian temples; the Cretan chorus, moving in measured pace, sang hymns to the Greek god, Apollo; and one of the Muses (Terpsichore), themselves daughters of Zeus, was the especial patroness of the art. The Phrygian Corybantes danced in honour of Rhea to drum and cymbal; at Rome, during the yearly festival of Mars, the Salian priests sang and danced, beating their shields; among the ancient Jews, Miriam danced to a song of triumph—itsself an act of worship, and David danced in procession before the Ark of God. A survival of religious dancing is still seen even within the pale of Christendom, where during the Corpus Christi Octave a ballet is danced every evening before the high altar of Seville Cathedral, by boys from twelve to seventeen years of age, in plumed hats and the dress of pages of Philip III.'s time.

Dancing and imitative acting in the lower stages of civilisation are identical, and in the sacred dances of ancient Greece we may trace the whole dramatic art of the modern world. Aristotle ranked dancing with poetry, and Pindar applies the name of the dancer even to Apollo. The dancing-master in *Le Bourgeois Gentilhomme* asserts that the destinies of the nations depend on the science of dancing; and Lucian, in a well-known dialogue, proves that the art is superior to tragedy, and coeval with the world itself. Sir John Davies, in his long poem, the *Orchestra*, illustrates the origin and importance of dancing, tracing in it all the motions of nature:

For what are breath, speech, echoes, music, winds,
But dancings of the ayre in sundry kinds.

The Spartans practised dancing as a gymnastic exercise, and made it compulsory upon all children from the age of five. Cicero says, 'No one dances sober unless he chances to be mad;' and indeed sedate Romans in general considered it disgraceful for a free citizen to dance, except in connection with religious ceremonies, but willingly enough witnessed the performances of professional dancers, like the *Almê* of modern Egypt, and the Bayaderes or Nautch girls of India. The early Christians practised choral dances, which came into discredit with the love-feasts or *Agape*. St Augustine says, 'it is better to dig than to dance,' and many of the Fathers condemned the practice as vigorously as our Puritan ancestors, who

saw deadly kin in 'promiscuous dancing.' St Chrysostom says dancing came first from the devil, and Father Mariana tells us the famous *saraband* worked more mischief than the plague. The *fandango* was hotly condemned by the clergy, but when danced before the Sacred College, who wished to see it before finally prohibiting it, so charmed the grave judges that they gave it their unanimous approval. Many of the medieval dances were solemn and stately in character, like the *danses basses*, which were danced to psalm-tunes at the court of Charles IX. of France; while it was not uncommon to see the princes of the church themselves treading a measure, and it is said the whole august Council of Trent danced at a ball given in 1502 to King Philip II. of Spain. The more lively *galliarde* and *voltu* were introduced into France from Italy by Catharine de' Medici, but it was not till the reign of Louis XIV., himself an enthusiastic dancer and performer in the court ballets until cured by some verses about Nero in Racine's *Britannicus*, that dancing reached its height in France. A Royal Academy of Dancing was founded in 1662, at the head of which was the famous Beauchamps, from whom the king took a dancing lesson every day for twenty years. Later great dancing-masters in France were Pécour, Marcel, and Noverre. Among dances that successively were paramount in society in France were the graceful *minuet*, the favourite for a century; the *quadrille* or *contre-danse*, often connected erroneously with the English country-dance; the *Ecossoise*, first introduced in 1760; the *galop*, a death-blow to the 'poetry of motion,' introduced from Germany; the *cotillon*, fashionable under Charles X.; the *polka*, first danced at the Odéon in 1840 by a dancing-master from Prague; the *polka tremblante*, or *schottisch*, also of Bohemian origin, first brought out in Paris in 1844; the *lancers*, introduced by Laborde in 1836; and the *waltz*, originally Bavarian, and which, now considerably modified from its original form, promises to maintain its supremacy. The French provide the world with fashions, and society everywhere in Europe has followed their lead. The people, however, have preserved their own old national dances, and these are still danced in every corner of Europe, stamped everywhere with as distinct an impress of nationality as the grave Basque *mutchiko*, or the *cachucha*, the *fundango* and *bolero* of southern Spain. Characteristic again of particular races or merely of classes of people are such forms of the dance as the Scotch *reel*, *Highland-fing* and *strathspey*, the Irish *jig*, *nigger break-downs*, sailors' *hornpipes*, *step-dances*, the *can-can*, *morris-dances*, and the like.

See the articles on the *BALLET* and on the several dances; the excellent books by Czerwinski, *Geschichte der Tanz-kunst* (Leip. 1862), *Die Tänze des 16. Jahrh.* (Danzig, 1878), and *Brevier der Tanz-kunst* (Leip. 1879); also Voss, *Der Tanz und seine Geschichte* (Berlin, 1868).

Dancing Mania, a form of epidemic disorder allied to Hysteria (q.v.), and evidently the result of imitative emotions acting upon susceptible subjects, under the influence of a craving for sympathy or notoriety. There is little doubt that imposture entered to a considerable extent into all the epidemic forms of the dancing mania, which indeed were usually attended and followed by consequences that showed but too clearly the presence of impure motives; but there is also evidence that in many cases the convulsive movements were really beyond the control of the will, whatever may have been the original character of the motives that prompted them. Epidemics of this sort were common in Germany during the middle ages, and are formally described as early as the 14th century; in Italy, tarantism, a somewhat similar disease, was ascribed

to the bite of a spider called the *Tarantula* (q.v.) and similar convulsive affections have been witnessed in Abyssinia and India, and even in comparatively modern times and in the most civilised countries in Europe, under the influence of strong popular 'excitement, especially connected with religious demonstrations. But the true dancing mania of the middle ages had its theatre chiefly in the crowded cities of Germany.

In July 1374 there appeared at Aix-la-Chapelle assemblies of men and women, who, excited by the wild and frantic, partly heathenish, celebration of the festival of St John, began to dance on the streets, screaming and foaming like persons possessed. The attacks of this mania were various in form, according to mental, local, or religious conditions. The dancers, losing all control over their movements, continued dancing in wild delirium, till they fell in extreme exhaustion, and groaned as in the agonies of death; some dashed out their brains against the walls around. When dancing they were insensible to external impressions, but haunted by visions, such as of being immersed in a sea of blood, which obliged them to leap so high, or of seeing the heavens open, and the Saviour enthroned with the Virgin Mary. The frenzy spread over many of the towns of the Low Countries. Troops of dancers, inflamed by intoxicating music, and followed by crowds, who caught the mental infection, went from place to place, taking possession of the religious houses, and pouring forth imprecations against the priests. The mania spread to Cologne, Metz, and Strasburg, giving rise to grave disorders, impostures, and profligacy. These countries were generally in a miserable condition; and arbitrary rule, corruption of morals, superstition, and insecurity of property, had already prepared the wretched people, debilitated by disease and bad food, to seek relief in the intoxication of an artificial delirium. Exorcism had been found an efficacious remedy at the commencement of the outbreak; and in the beginning of the 16th century, Paracelsus, that great reformer of medicine, applied immersion in cold water with great success. At the beginning of the 17th century it was already on the decline; and we now hear of it only in single cases as a sort of nervous affection. See *CHOREA*, *CONVULSIONARIES*, *VITUS* (St), and Hecker's *Epidemics of the Middle Ages* (Eng. trans. 3d. ed. 1859).

Dancourt, FLORENT CARTON, a French dramatist, born in 1661. At one time an actor and a favourite of Louis XIV., he became devout in his old age, which he spent in retirement in the country. He died in 1725. He was a prolific author, and excelled in depicting the stupidity of the peasantry and the follies of the *bourgeoisie*. Of his plays the best are *Les Bourgeoisies de Qualité*, *Le Chevalier à la Mode*, *Le Galant Jardinier*, and *Les Trois Cousines*.

Dandelion (*Taraxacum officinale*, formerly *Leontodon Taraxacum*) is a ligulifloral composite, common in several varieties or sub-species throughout Britain and the whole of Europe, in pastures and by waysides, and now also so perfectly naturalised in many parts of North America as to be there one of the most familiar spring-flowers. The names Dandelion and Leontodon (Fr. and Gr., 'lion's tooth') both have reference to the form of the leaves. The whole plant abounds in a milky juice, containing a peculiar crystalline principle called *Taraxacin*; has a bitter taste, and valuable medicinal properties. Roasted and ground, dandelion-root is sometimes used as a substitute for coffee. *Dandelion Coffee*, however, is usually a mixture of ordinary coffee and the powder or extract of dandelion-root; and *Dandelion Chocolate* is composed of

one part of common chocolate and four parts of the powder of dandelion-root. The young leaves, when blanched, are a good salad, resembling lettuce or endive.

Dandolo, a famous Venetian family, which gave four doges to the republic. The most illustrious of its members was Enrico, born about 1110 or 1115 A.D. Eminent in learning, eloquence, and knowledge of affairs, he ascended from one step to another, until, in 1173, he was sent as ambassador to Constantinople, and in 1192 was elected doge. In this latter capacity he extended the bounds of the republic in Istria and Dalmatia, defeated the Pisans, and, in 1201, marched at the head of the crusaders. He subdued Trieste and Zara, the coasts of Albania, the Ionian Islands, and Constantinople, 17th July 1203. When the Emperor Alexius was murdered by his own subjects, Dandolo laid siege to Constantinople, and took it by storm, 13th April 1204. He established there the empire of the Latins, and caused Count Baldwin of Flanders to be chosen emperor. By his exertions Venice obtained possession of several Greek islands and large territories in Greece. Dandolo died at Constantinople, 1st June 1205. See CRUSADES, VENICE.—Giovanni Dandolo was doge, 1280–89; Francesco, 1328–39; Andrea, 1342–54.

Dandy Fever. See DENGUE.

Dan'ebrog ('the Danish banner') is the name of the second in dignity of the Danish orders instituted by King Waldemar in 1219.

Danegeld, a tax levied on land, originally to buy off the Danes. It was first raised by Ethelred II., was abolished by Edward the Confessor, reimposed at a higher rate by the Conqueror, and finally abolished under Henry II.

Dane-lagh (*Danelaw* or *Denalagu*), the name applied to that part of England in which Danish influence was at one time paramount, and which still shows in the blood of the natives and in popular place-names a distinct Danish impression. At various times it ranged along the coast counties from Yorkshire to Essex. The southern part of the old province of Deira was the most thoroughly Danish part of the whole district, and here the typical Danish endings for place-names, *thorpe*, *caster*, and *by*, are still the most common. Next to Yorkshire came Lincoln, with Lindsey for its centre. The least Danish part of the Dane-lagh was East Anglia and Essex. Deira and Lindsey were divided into *ridings* or *trithings*, and these again into *wapentakes*, like the *hundreds* of southern counties.

Danes' Dyke. See FLAMBOROUGH HEAD.

Dangerfield, THOMAS (1650–85), an accomplice of Titus Oates (q.v.).

Dangs, THE, a hilly tract within the limits of the presidency of Bombay, in 20° 22'–21° 5' N. lat., and 73° 28'–73° 52' E. long., with an area of about 1000 sq. m., and a pop. (1881) of 45,485, belonging almost entirely to the wild forest tribes. Densely wooded, and shut in by steep hills, with a heavy rainfall and a close atmosphere, the country is singularly unhealthy. It is ruled by fifteen petty chiefs, with from 134 to 14,205 subjects respectively. The Bhils (q.v.) are the most important tribe; they have charge of the police and of the district treasuries. The only important products are the teak and other timber-trees.

Daniel (Heb., 'God is judge') is mentioned by Ezekiel (6th century B.C.), along with Noah and Job, as a great example of righteousness and wisdom (Ezek. xiv. 14, 20, and xxviii. 3). According to the book which bears his name, he was one of the Jews carried away to Babylon in

the reign of Jehoiakim, king of Judah, and gained a high position at the court of Nebuchadnezzar, which he maintained also under Darius and Cyrus, notwithstanding all the intrigues of hostile courtiers. The book stands in our Bible, as well as in the LXX. and Vulgate, immediately after Ezekiel, while in the Hebrew canon it is not included in the collection of the Prophets, but appears among the miscellaneous 'Writings' (see BIBLE). Delitzsch points out that the book nowhere claims to be written by Daniel, and that its position in the canon shows that it is not properly a prophetic book, but an apocalypse. It is written partly in Hebrew, partly in Aramaic, but forms a coherent whole, which is now divided into twelve chapters, the first half consisting of narrative, the second half of predictions. These predictions are not prophetic speeches like those of the other prophetic scriptures, rebuking the sins of contemporaries, foretelling judgment on the impenitent, and promising Messianic salvation to the repentant and believing; they are minutely detailed apocalyptic visions embracing the history of four successive world-empires—the Chaldean, the Median, the Persian, and the Greco-Macedonian—culminating in the establishment of the eternal kingdom of the saints of the Most High. Objections to the Danielic authorship of the book were made by the Neoplatonist Porphyry as early as the 3d century A.D., but first found support in the critical investigations of Bertholdt (1806–8), followed by those of Bleek, De Wette, Langerke, Ewald, Lücke, and others. These investigations have led to the view that the book was not written till the time of the religious persecution of Antiochus Epiphanes, about 168–165 B.C. But the book is certainly of great importance, and 'has exercised,' says Schürer, 'a profound influence upon the form of the Messianic idea. . . . In this book (xii. 2) the hope in a resurrection of the body is for the first time plainly and decidedly expressed. The Messianic hope is here the hope of a glorious future for the nation, but with the double modification that the future kingdom of Israel is conceived of as a universal kingdom, and that all the saints who have died will share in it.' According to Delitzsch, our Lord's testimony in Matt. xxiv. 15 proves 'that Dan. ix. 26, *et seq.*, is a prophecy of the desecration of the temple in the Roman war, not that it is a prophecy then fulfilled for the first time.' See Hilgenfeld, *Die Jüdische Apokalypitik* (1857), and the special commentaries by Hitzig (1850), Auberlen (3d ed. 1874), Hilgenfeld (1863), Caspari (1869), Pusey (1864), Desprez (1879), and Robinson (1882).

Daniel, SAMUEL, poet, was the son of a music-master, and was born in 1562 near Taunton, Somersetshire. He entered Magdalen Hall, Oxford, in 1579, but 'his glory being more prone to easier and smoother studies than in pecking and hewing at logic,' quitted the university without taking a degree. He was some time tutor at Wilton to William Herbert, son of the Earl of Pembroke and Sir Philip Sidney's sister; afterwards at Skipton to Anne Clifford, daughter of the Earl of Cumberland. In 1603 he was appointed to read new plays, and twelve years later he had for some time charge of a company of young players at Bristol. In 1607 he became one of the queen's grooms of the privy chamber. Towards the close of his life he retired to a farm which he possessed at Beckington, in his native county, where he died in October 1619. Daniel was highly praised by his contemporaries, as Lodge, Carew, Drummond of Hawthornden, although Ben Jonson described him as 'a good honest man . . . but no poet,' and Drayton quotes the opinion of some wise men that he was 'too much historian in verse,'

besides saying for himself that 'his manner better fitted prose.' Of modern critics, Coleridge, Lamb, and Hazlitt unite in praising him. As a sonneteer Daniel is altogether admirable. Some of the 'Delia' series rank near the best examples of this form in English. Daniel is indeed an elegant if not a great poet. His writings are pervaded by a moral thoughtfulness and purity of taste remarkable indeed, but lacking that vital energy of movement and memorableness of expression which spring from genuine inspiration. The 'well-languaged Daniel' is therefore not the most interesting of the Elizabethans, although his style is quite modern. His works include sonnets, epistles, masks, and dramas; but his chief production is a poem in eight books, entitled a *History of the Civil Wars between York and Lancaster*. His *Defence of Ryme* (1602) is written in admirable prose. Dr Grosart reprinted Daniel's works in the Huth Library (3 vols. 1885-87).

Daniell, JOHN FREDERIC, scientist, was born in London, March 12, 1790. He was for a time engaged in a sugar-refining work, but was elected a Fellow of the Royal Society in 1814, and devoted himself to chemistry and meteorology. In 1823 he published his *Meteorological Essays*, and in 1824 the Horticultural Society awarded him their silver medal for an essay on artificial climate. In 1831 he was appointed professor of Chemistry in King's College, London; and in 1839 published his *Introduction to Chemical Philosophy*. In 1843 he received the degree of D.C.L. from the university of Oxford, and obtained all the three medals in the gift of the Royal Society. He invented a hygrometer (1820), and a new pyrometer (1830), as well as the electric battery known by his name; and he wrote many valuable papers on chemistry, especially on voltaic combinations and electrolysis. He died suddenly, March 13, 1845.

Danish Literature. See DENMARK.

Danites, or DESTROYING ANGELS, a secret society founded by Joseph Smith in 1838, professedly merely for the defence of the Mormon sect against the mob. The members, originally some 300 in number, were bound by an oath, under penalty of death, to sustain the 'first presidency' and one another in all things, whether right or wrong. They were divided into companies of fifties and tens, with suitable officers, and a general over the whole; special 'destruction companies' were appointed for the purpose of burning and destroying, at first by way of reprisal; but afterwards assassinations, to fulfil prophecies of Smith's, were laid to their charge. Remembrance of the society's operations was revived by the trial, conviction, and execution of Bishop John D. Lee, in 1877, for the massacre of a train of 140 non-Mormon emigrants at Mountain Meadow, near Utah, twenty years before.

Dannecker, JOHANN HEINRICH VON, a German sculptor, was born at Waldenbuch, in the district of Stuttgart, 15th October 1758. His parents were in the humblest circumstances; but through the favour of the Duke of Württemberg, he received a good education at the military academy at Ludwigsburg. His artistic talents were rapidly developed. In 1780 he obtained the prize for the best model of 'Milo;' and in 1783 went to Paris, where he studied for two years; after which he returned to Rome, where he met Goethe, Herder, and Canova, to the last of whom he was indebted for much valuable instruction. At Rome Dannecker remained till 1790. Here he executed in marble his statues of 'Ceres' and 'Bacchus.' On his return to Germany, the Duke of Württemberg appointed him professor of Sculpture in the Academy of Stuttgart, in which city he resided till

his death, 8th December 1841. Dannecker was undoubtedly one of the best of modern sculptors. His forte lay in expressing individual characteristics, in which respect he has not been surpassed. This gives a great value to his busts of distinguished persons, such as Schiller, Lavater, and Gluck. His perceptions of the beautiful and the delicate, especially in the female form, are also considered by his countrymen to be more exquisite and true than those of Canova himself. His earlier works are chiefly pagan in their subjects, while his later ones are Christian, and are pervaded by a pensive idealism. To the former belong 'Sappho,' 'Love,' 'Psyche,' and 'Ariadne on the Panther,' 1816 (at Frankfurt), regarded as his masterpiece; to the latter, 'Christ,' 'John the Baptist,' and 'Faith.'

Dannevirke ('Danes work'), the rampart built by the Danes in 808 across Sleswick, just north of the Eider, for defence against the Germans. It was from 25 to 35 feet high, and was the scene of fighting in 1849, after which its fortifications were destroyed.

Dante Alighieri (also written ALDIGHIERI, ALAGHIERI, and otherwise), 'that singular splendour of the Italian race,' as Boccaccio, his first biographer, calls him, was born in May 1265, the exact day being unknown. The house in which he was born is still shown in the Piazza di San Martino at Florence. His father was a lawyer, his mother, who was his father's second wife, was named Bella, but her surname is not known. The future poet was baptised with the Christian name of Durante, afterwards contracted into Dante, in the beautiful baptistery of Florence, towards which in his later years the tenderest thoughts of the hopeless exile turned (see *Inf.* xix. 17; *Par.* xxv. 1-12). The fancy of the old biographers loved to dwell on the appropriateness of both names, 'the much-enduring,' and 'the giver.' As with many other great men, a halo of legend surrounds the circumstances of his birth and early years. But the curtain is first lifted on his actual history, and that by himself, in his *Vita Nuova*, the New (i.e. probably Early) Life, when he relates how he first set eyes on 'the glorious lady of his heart, Beatrice,' he being then about nine years of age, and she a few months younger. To Boccaccio, and to his statement alone, we owe the generally accepted fact that she was the daughter of Folco Portinari, for Dante himself never gives the slightest clue as to her family name. Owing to his reticence on this point, combined with the extraordinary and, to modern notions, almost unintelligible amount of idealisation in Dante's language about her, some critics have (as might be expected) denied that she was a real person at all. That chance meeting in May 1274 determined the whole future course of the poet's life. The story of his boyish but unquenchable passion is told with exquisite pathos in the *Vita Nuova*. There is no evidence that any similar feeling was aroused in the heart of Beatrice Portinari. She was married at an early age to one Simone de' Bardi, but neither this nor the poet's own subsequent marriage interfered with his pure and Platonic devotion to her. This became even intensified after her death, which took place on June 9, 1290, when she was in her 24th year. Shortly after this Dante married Gemma Donati, a member of one of the most powerful families of the Guelph faction at Florence. According to Boccaccio, this marriage was recommended by his friends, alarmed at the condition of his health through overmuch sorrow. It has commonly been assumed that the marriage was an unhappy one. This, however, is merely a conjecture, supported mainly by the fact that after Dante's exile in 1301 he never appears to have seen, or cared to see, his wife again.

In 1289 Dante took part in the battle of Campaldino, in which the Florentines and their Guelphic allies defeated the Ghibelline league of Arezzo. The flight and death of Buonconte, who fought on the opposite side, is the subject of one of the most splendid episodes in the *Divina Commedia* (*Purg.* v.). Later in the same year he was present at the capitulation of Caprona, as he himself tells us in *Inf.* xxi. 94. With these experiences his military life seems to have closed. Soon after, we find him beginning to take part in politics, and according to the custom of the times, he first became registered in one of the city guilds—viz. that of the Apothecaries, he being then thirty years of age. It is interesting to note that he is there entered as 'Dante d'Alighieri, poeta.' It should, perhaps, have been mentioned that we know little of his early education, except that he is said to have studied at the then celebrated university of Bologna, and that he was certainly for some time a pupil of Brunetto Latini, of whom he speaks with the utmost veneration and affection, though a stern sense of justice compels him to place him in Hell (*Inf.* xv.). At the outset of his public life his sympathies were with the Guelph party, to which he would naturally have been attached by family ties both through his father and his wife. After filling minor public offices, and possibly going on some embassies abroad (though, doubtless, not all of those which later writers in their admiration have attributed to him) in the ever-memorable year 1300, the *mezzo cammino* of his own life, when he was thirty-five years old, the beginning of a new century, the year of the first Jubilee at Rome, the assumed year of the great poetic vision of the *Commedia*, he attained to the dignity of one of the six priors of Florence. That singular office, lasting for only two months, seems (as Mr Lowell suggests) to have been invented by the Florentines 'apparently to secure at least six constitutional chances of revolution in the year.' It should be explained that this was a very critical and stormy period at Florence. Not only was the eternal feud of Guelph and Ghibelline in full force, but a new excuse for party hatred had been found in the distinction of Black and White Guelphs, the latter being the more moderate party, who tended to verge towards the Ghibellines, and under certain circumstances to make common cause with them. So far as Dante could be called 'a party man' at all (see *Par.* vi. 100-3; xvii. 68-69), it was towards this section that his sympathies tended. His office as prior lasted from June 15 to August 15 in the year 1300. He distinguished his brief tenure of office by procuring the banishment of the heads and leaders of the rival factions by which Florence was torn asunder. He carried out this process with characteristic sternness and impartiality on Guelph and Ghibelline, White and Black alike, unmoved by any considerations of relationship, friendship, or political sympathy. Shortly afterwards the leaders of the Whites were permitted somehow to return. The partiality thus shown was a prominent feature in the accusation against Dante; but he had a complete answer in the fact that he was no longer in office at the time that it occurred.

In the following year, 1301, and probably in the autumn, in alarm at the threatened interference of Charles of Valois, who had now crossed the Alps, Dante was sent on an embassy to Rome to Pope Boniface VIII., under whose instigation Charles was acting. From that embassy he never returned, nor did he ever again set foot in his native city. For meanwhile had occurred the dreaded advent of Charles, nominally as peacemaker, on November 1, 1301. He espoused the side of the *Neri* or Blacks, and for three days the fight raged in the streets of Florence. Finally, the victory of the *Neri* was

complete, their opponents were slain or banished, and their houses sacked. Soon after, in January 1302, the sentence of banishment went forth against Dante and others, nominally on the charge, an utterly baseless one, of *baratteria*, or malversation in the office of prior in 1300. This was followed by a yet severer sentence on March 10, condemning them to be burned alive if ever caught, which was repeated again on September 2, 1311, and yet once more on November 6, 1315. We need not attempt here to follow the wanderings of his exile of twenty years. He made at first one or two hopeless attempts to return, but abandoned them, partly in disappointment at their failure, partly in disgust at the kind of associates with which such proceedings linked him (see *Par.* xvii. 61-69).

His principal halting-places seem to have been—first Verona, under the protection of one of the Della Scala family, described by him as 'gran Lombardo' with much eulogy in *Par.* xvii. 71. Then in succession he sojourned in Tuscany (with Count Salvatico), in the Lunigiano (with Moruello Malaspina), near Urbino (with Ugucione della Faggiuola), and then at Verona again. During this period he is said to have visited Paris; but though there seems little doubt that he was actually there at some time of his life, yet some of his biographers connect this visit with the period of his early education. Among these is Serravalle, who wrote, it should be noted, as late as 1417, and who is also the sole authority for Dante's alleged visit to England and Oxford. Those who, like Boccaccio, take him to France during his exile, suppose him to have been recalled to Italy and politics by the election of Henry of Luxembourg as emperor, and his visit to Italy, where no emperor had set foot for more than fifty years (see *Purg.* vi. 105, &c.). The exile's hopes were now roused to the highest pitch, and he addressed an epistle to Henry, couched in language borrowed largely from Scripture, which to our ears sounds extravagant. His hopes were once more and finally crushed by Henry's unexpected death on August 24, 1313, after which Dante took refuge in Romagna, and finally in Ravenna, where for the most part he remained, under the protection of Guido Novello da Polenta, until his death. This took place on September 14, 1321. The precise cause of it is unknown. He was no doubt utterly broken in spirit and in health. He had been employed by his patron in an embassy to Venice, which proved unsuccessful, and he died very soon afterwards, as some biographers say, from grief and annoyance at his failure at Venice, and as others, with more probability, assert, from the effects of a fever, aggravated if not originally caused by the unhealthy marshes which he had traversed on his return to Ravenna by land, the Venetians having harshly refused to allow him to make the journey by sea.

He was buried with much pomp by his friend Guido at Ravenna, and there he still lies. At some unknown period, by unknown hands, and from a motive still unexplained, his body was removed from the sarcophagus in which it lay, and was walled up in the neighbouring church of St Francis, in a rough box, inscribed *Dantis Ossa*. There it was discovered by pure accident on May 27, 1865, and after the bones had been identified beyond possibility of doubt, they were replaced in the sarcophagus, from which it was found they had been abstracted. Dante had seven children, six sons and one daughter, Beatrice, who was a nun in a convent at Ravenna. His family, however, became extinct in the 16th century. His personal appearance is too well known to need much description. Fortunately, a cast was taken from his face after death, so that we have an absolutely

authentic record of his features. Boccaccio also, writing not very many years after his death, has preserved numerous personal details, such as that he was of moderate stature, stooping when he walked, slow and dignified both in gait and speech, reserved and taciturn in habit, but, when he spoke, keen, sarcastic, and often contemptuous. That he was devoted to music and painting appears from many passages in his works, as well as from current tradition.

The dates and sequence of his various works are a matter of conjecture, and are still very much disputed. Doubtless the *Vita Nuova* is the earliest. By far the most celebrated is the *Divina Commedia*, the pre-eminent greatness of which has tended to eclipse his other writings, which do not generally receive the attention they deserve. In this poem he purposes, and assuredly fulfils his purpose, 'to say of Beatrice that which never yet was said of any woman' (end of *Vita Nuova*). In this vision of Hell, Purgatory, and Heaven, we have, as it were, an encyclopedic view of the highest culture and knowledge of the age on philosophy, history, classical literature, physical science, morals, theology. All this, moreover, is expressed in the sublimest and most exquisite poetry, and with consummate power and beauty of language. The *Divina Commedia*, indeed, may be said to have made the Italian language, which was before so rude and unformed that Dante himself hesitated to employ it on such a theme, and is said to have commenced his poem in Latin. No work probably in the world, except the Bible, has given rise to so large a literature. To say nothing of nearly six hundred MSS. in which it was copied before printing became common, there have been published about three hundred editions; it has been no less than a hundred times translated into various European languages; and of commentaries, introductions, essays, and monographs there is no end. About fifty years after Dante's death, a public lectureship on the *Divina Commedia* was established at Florence, to which Boccaccio was first appointed.

The next most important work (and one throwing much light on the *Commedia*) is the fragment called the *Convito*, or *Banquet*. It takes the form of a commentary on some *canzoni*, or short poems, of the author, of which there are only three, though the work, if completed, would have contained fourteen of these 'courses,' as the author calls them. Its contents are almost as encyclopedic as those of the *Commedia*. The *De Monarchia* (written in Latin) expounds Dante's theory of the right, and, as he held, divinely-intended, government of the world, by a universal emperor acting in harmony with a universal pope, respectively administering, without conflict or interference, the temporal and spiritual affairs of mankind. Another work, again unfinished, since it consists of two books only, when four were promised, is the *De Vulgari Eloquentia*. It also is written in Latin, and is a discussion of the origin of language, the several divisions of languages, and the numerous dialects of Italian in particular. A considerable collection of short poems, *canzoni*, sonnets, &c., is also preserved under the title of the *Canzoniere*, and finally, we have about a dozen epistles addressed mainly to leading statesmen or rulers, and dealing with the most urgent political problems of the day. There are also some *Ecloques* and other minor works, as well as several of doubtful authenticity which are sometimes assigned to him.

The editions most to be recommended are as follows: For the *Commedia*, Brunone Bianchi, or Fraticelli, are the most serviceable for ordinary students; for a more thorough and critical study, Scartazzini (3 vols.) is indispensable; for the *De Monarchia* and the *Vita Nuova*,

the editions of Witte; for a complete edition of all the works, Fraticelli, or (for all except the *Commedia*, which he did not live to publish) Giuliani, the notes of the latter being much fuller. By far the best text of the *Commedia* yet published, and one leaving very little to desire, is that of Witte (Berlin). For the bibliography of the *Commedia* (including the description of its numerous MSS.) there is the invaluable *Bibliografia Dantesca* of Colomb de Batines up to 1845, continued by Carpellini (1845-65), and by Fetzholdt (1865-80). An extremely useful and handy little book for all students of the *Commedia* is L. G. Blanc's *Vocabolario Dantesco*. For a general introduction for English readers to the life, character, and works of Dante, and especially to the *Divina Commedia*, by far the best book is the essay entitled 'A Shadow of Dante,' by Maria Francesca Rossetti. The principal English translations in verse are by Cary, Wright, Cayley, Pollock, Longfellow, Plumptre, Hazelfoot, Rossetti, and Sibbald (the last two the *Inf.* only); and in prose by Carlyle (*Inf.* only) and Butler (*Purg.* and *Par.* only).

Danton. GEORGES-JACQUES, was born of good farmer-people, at Arcis-sur-Aube, 28th October 1759. The outbreak of the French Revolution found him a quiet and studious man, practising as an advocate in Paris, but ere long its fever filled his veins. It was not till 1792, however, that he became a great leader, as we find no trace of his influence in such movements as the destruction of the Bastille and the forcible removal of the court from Versailles to the Tuileries. Mirabeau quickly detected Danton's genius, and hastened to attach him to himself, but his death in the spring of 1791 removed the last stay to the speedy downfall of the monarchy and the onward progress of a turbulent and infatuated democracy. Along with Marat and Camille Desmoulins, Danton instituted the Cordeliers' Club, which soon became the rallying-point of all the hotter revolutionists. There the tall brawny man—a born Tribune—with harsh and daring countenance, beetling black brows, and a voice of enormous power, thundered with vehement eloquence against the aristocrats, till the passions of the populace rose into ungovernable fury. Meantime the unhappy king stumbled into ever new blunders—most fatal, the attempt to flee from Paris (June 1791), and the affair of the Champ de Mars (July 2, 1791). Assertions have been made that Danton was after these events corrupted by the court, but there is no trustworthy evidence of this, and it is certain that his hostility to the monarchy remained as implacable as ever. 'The Mirabeau of the Sansculottes' was, indeed, says M. Claretie, 'a kind of bourgeois Mirabeau, equally powerful, but neither dissolute nor venal.' Danton's share in the insurrectionary march on the Tuileries (10th August 1792) is very doubtful, but it is certain that immediately thereafter he appears as Minister of Justice. And now the gigantic personality of the man seemed to overshadow all the surrounding figures. He stood forth as the incarnate spirit of the Revolution, manifesting alike its heroic audacity in the presence of danger from without, and its mad suspicion and terror of danger from within. The advance of the Prussians seemed for a moment to strike a panic to the heart of France. On the 2d of September Danton mounted the tribune, and addressed the Legislative Assembly in a speech of tremendous power, which closed with the famous words regarding the enemies of France: 'Pour les vaincre, pour les atterrer, que faut-il? De l'audace, encore de l'audace, et toujours de l'audace.' The heart of Paris was moved with resistless enthusiasm: she poured forth army after army of her sons, whose fiery valour quickly drove the invaders from the sacred soil of France. But the excitement of Paris was not all heroic—the September murders in the prisons were merely an outburst of cowardice and fear. Danton had no share

in this atrocity, for which Marat was mainly responsible, but he admitted that such excesses were incidental to a revolution, and condoned them as merely morbid and passing ebullitions of forces that would yet flow freely in healthy channels.

Danton voted for the death of the king (January 1793), was one of the nine original members of the Committee of Public Safety, and frequently went on missions to Dumouriez and other republican generals. In the Convention he now bent all his giant strength to crush the Girondists, or moderate party, on whose fall the extremists found themselves supreme. But he could not restrain the forces he had created, and his heart filled with ineffectual pity when the heads of opponents against whom he had thundered in debate fell under the merciless guillotine of the triumphant Mountain (October 1793). Danton was chiefly instrumental in setting up a strong central authority in the Committee of Public Safety and investing it with dictatorial powers, but he elected not to belong to it himself. Henceforth all his energies were devoted at once to fire the hearts of Frenchmen against the foreign enemy, and to conciliate domestic hatreds. He strove with all his might to abate the fanatical and pitiless severity of the revolutionary tribunal, but although Hébert and his party were cut off, Danton's policy of clemency failed to commend itself to the Mountain, whose ferocious instincts saw a more promising leader in the narrow and acrid Robespierre. A fruitless attempt was made to reconcile the two, but their interview left them worse friends than before. Meantime Danton was strangely careless of his fate. He went awhile for rest to his native Arcis, and forgot all the machinations of his enemies in the quiet of domestic happiness with the wife he had just married. 'I prefer being guillotined to guillotining,' he said to a friend—a great saying which history will remember. Soon his friends summoned him to return to Paris. When news was brought him that the warrant for his arrest was made out, he said merely, 'They dare not,' and calmly went to sleep as usual. Arrested at last, he carried his head high until his doom:—'I leave the whole business in a frightful welter. Not one of them understands anything of government. Robespierre will follow me; I drag down Robespierre. Oh, it were better to be a poor fisherman than to meddle with governing of men.'

On the 2d April 1794 he was brought with Camille Desmoulins and a group of his friends before the bar of the Revolutionary Tribunal he had formed a twelvemonth before. Asked his name formally by Fouquier-Tinville, the attorney-general, he replied with more than his customary greatness of phrase: 'My name is Danton: a name tolerably known in the Revolution; my abode will soon be annihilation; but I shall live in the Pantheon of history.' His defence was sublime in its audacity, its incoherence, its mixture of heroism and magnificent buffoonery. 'I sold to the enemy!' he exclaimed, 'A man of my stamp is priceless.' 'Do I look like a hypocrite?' was his only answer to one of the absurdest of the charges. The first two days of his trial his mighty voice and passionate eloquence moved the people so greatly that the Committee of Public Safety in terror hastily concocted a decree that the mouths of men who had 'insulted Justice' should be shut; and only with this shameful outrage upon justice were his enemies able to send to his doom the greatest figure that fell in the Revolution (April 5, 1794). At the foot of the scaffold the thought of his much-loved wife filled his heart, but with the words, 'Danton, no weakness,' he nerved his heart to die as he had lived. To the headman he said, 'Thou wilt show my head to the people; it is worth showing.'

The outlines of the Titan of the Revolution in Carlyle's glowing pages are none too heroic; his story is written large on the annals of his time. His private life, which was no less great in its purity and simplicity, has been investigated by Dr Robinet and M. Alfred Bougeart.

Danube (Lat. *Danubius*; in the lower course *Ister*; Ger. *Donau*; Hung. *Duna*; Slav. *Донау*), the second river of Europe, inferior only to the Volga, has its origin in the Breg and Brigau mountain-streams rising in the Black Forest, Baden, and uniting at Donaueschingen, 1,460 feet above sea-level. The Danube has a total including windings, of 1740 miles, and drains an area estimated at 315,000 sq. m. It flows first S. to Gutmadingen, and then N.E. to Ulm (1515 feet above sea-level), which may be taken as the head of its upper course. A few miles above Ulm it receives on its right bank the Iller, from which point it is navigable for boats of 100 tons. At Regensburg (Ratisbon) the river reaches its most northerly point (49° 2'), and from thence its course is generally S.E. to the northern frontier of Bulgaria. Between Ulm and Passau, where it leaves German territory, it receives, among other tributaries, the three large alpine streams, the Lech, Isar, and Inn, on the right, and the Altmühl and Regen on the left bank. At Passau its width is 231 yards, and its depth 16 feet. The crystalline rocks of the Bohemian Forest mountains follow the stream into Austria, and as far as Aschach its banks are wild and picturesque. It flows E. to Presburg with little variation of course, receiving the Enns from the S., and the March or Morava from the N.; and it passes from the Austrian dominions through an opening, called the Carpathian Gate, between the Leitha chain and the Lesser Carpathians, where its width is 320 yards, and its depth 20 feet. Between Presburg and Komorn the stream divides, and forms the Great and Little Schüttlen, or alluvial islands. Near Waitzen it turns directly S., and enters upon the Hungarian plain, a vast sandy alluvial flat, in which it is continually forcing new channels and silting up old ones; it maintains this course for 230 miles, receiving from the N. the Waag and the Gran, while the Drave from the W. adds considerably to its volume.

After this last accession, the Danube turns again S.E., and, increased by the waters of the Theiss and Temes from the N., sweeps past Belgrade, where it is joined by the Save, and forms the boundary between Hungary and Servia. At Semlin, near Belgrade, it is 1706 yards wide and 46 feet deep, but the width is greatly contracted by spurs of the Transylvanian and the Servian mountains for 75 miles beyond Ujpalanka. Within this stretch are eight distinct rapids, shut in by lofty walls, and strewn with rocky shoals of limestone, crystalline schists, and granite. The lower Klissura is the most strikingly picturesque of these, but the most difficult passage is the shortest (1½ mile) of the eight—the 'Iron Gate,' properly so called, below Orsova, where the middle course of the river ends. Here the stream has a breadth of only 129 yards, and the piled-up waters attain a depth of 28 fathoms; ledges of rock lift their tooth-like points above the surface, and all around a seething stretch of whirlpools, cataracts, eddies and counter-eddies, combines with the river's rapid fall to present a serious and formerly impassable obstacle to navigation. Many attempts have been made to improve the bed here, which, under article 57 of the Berlin Treaty, Austria bound herself to clear; but prior to 1889 little had been effected: only when a depth of at least 8 feet covered the obstructions could steamers drawing 5 feet make the passage. From here the Danube enters on the Wallachian depression, and flows in a

wide stream, through a district fertile indeed, but solitary and poorly cultivated, constantly broadening into a lake, or overspreading its banks with swamps. It drains the country between the Transylvanian mountains and the Balkans, forming the northern boundary of Bulgaria as far as Silistria; and from here it turns northward, skirting the Dobruja, and flows between marshy banks to Galatz, receiving on the way the Jalomitza and the Sereth. From Galatz it flows E., and, after being joined by the Pruth from the N., SE. to the Black Sea. The delta, which begins 5 miles W. of Tuldja, is a vast wilderness, covering an area of 1000 sq. m., and resembling an immense green sea of rushes; it is cut up by numerous channels and lakes, and is the haunt of sea-birds, wolves, and buffaloes. The farthest mouths are 60 miles apart. Two-thirds of the Danube's volume passes through the Kilia, but this arm forms a secondary delta near its outlet, and the southern or St George branch also forms two channels; it is consequently by the middle or Sulina mouth that ships enter, although it discharges only $\frac{2}{3}$ of the river's waters. The improvements (1858-71) of this mouth, originally intended to be temporary, have increased the depth over the bar from 9 to 20 feet, and the proportion of ships wrecked has fallen from 8 to 2 per 1000. To defend Vienna against risk of inundation, the course of the Danube skirting it was, in 1868-81, diverted into an artificial channel, and the bed has since been improved, above and below the city, from the mouth of the Ispër to that of the March. Similar works have been undertaken near Pesth, and in 1888 the Hungarian diet voted 500,000 florins for preliminary works towards the removal of the impediments to navigation at the Iron Gate. Until then any effectual improvements of that passage had never advanced beyond the stage of projects, while throughout Hungary and along the lower course inundations had caused great damage. The first effect of this vote was to create no little panic among the Danubian towns, which foresaw for themselves the possibility of bombardment by a hostile flotilla at any time; and in Austria the construction of gunboats, torpedo boats, and fortifications was at once proposed. The Danube has about 400 tributaries, 100 of them navigable, and the Danube Steam Navigation Company (1830), which has done much to increase the commerce, possesses nearly 200 steamers and over 700 iron tow-boats; other companies also have placed steamers on the upper portions of the river. Nevertheless, owing to the obstructions and to the shifting course of the stream, the tonnage of the Danube trade is inferior to that of the Elbe. The Danube is connected with the Rhine by means of the Ludwigs-Canal (1844), and with the Elbe by means of the Moldau and Mühl, and canals.

THE INTERNATIONAL DANUBE NAVIGATION COMMISSION was constituted in 1856, when at the Peace of Paris the navigation of the river was declared free to all nations, and was composed of delegates of all the great powers, to whom a representative of Roumania has been added since 1878. It was appointed on the express condition that it should dissolve in 1858, but such was its usefulness that it was informally continued till 1866, when the Conference of Paris formally prolonged its powers for five years. In 1871 the Conference of London continued the Commission for twelve years, and in 1883 a second London conference extended its existence for other twenty-one years. It exercises almost sovereign power on the mouths of the Danube, where it has conducted the great engineering works already referred to; it has its own flag, uniform, and revenue, and has raised loans, made laws, and maintained its own small army of police. Its jurisdiction, originally limited

to the river between Isaktscha and the sea, was extended at the Congress of Berlin (1878) as far as Galatz, and afterwards to the Iron Gate; but in the last-named portion of the stream its authority is exercised only by delegation to the Riverain Commission of the states on the bank (also constituted in 1856), or on appeal from its decisions.

Danubian Principalities, a name applied to Moldavia and Wallachia. See ROUMANIA.

Danvers, a post-village of Essex county, Massachusetts, 4 miles NW. of Salem, with manufactures of shoes, carpets, bricks, &c. It is the seat of the state asylum for the insane. Peabody, 3 miles to the south, was formerly South Danvers. Pop. (1885) 7048.

Danville, (1) capital of Vermilion county, Illinois, on the Vermilion River, 132 miles S. of Chicago by rail. It is an important railway junction, and contains railway-shops, besides a number of steam-mills and foundries, and organ and chair factories. Bituminous coal is mined near by. Pop. (1880) 7733.—(2) Capital of Montour county, Pennsylvania, on the north branch of the Susquehanna, 68 miles N. by E. of Harrisburg by rail. The place was first settled in 1768, and the Pennsylvania Ironworks here is the oldest establishment in the United States for the manufacture of railroad iron. There are also numerous blast-furnaces, foundries, and rolling-mills, and the annual value of the iron forged and rolled here has sometimes reached \$5,000,000. Pop. 8346.—(3) A flourishing town of Virginia, on both sides of the Dan River, here spanned by an iron bridge, 141 miles SW. of Richmond by rail, with a female college, large cotton and other mills, and a very important trade in tobacco. Pop. (1880) 7526; (1888) 16,000.

D'Anville, JEAN BAPTISTE BOURGUIGNON, a geographer and map-maker, was born at Paris, 11th July 1697, and devoted himself to mathematical and geographical studies with such zeal and success that in 1719 he was appointed geographer to the king. He died 28th January 1782. He published in all 211 maps; the most notable collections were the *Atlas Général* (1737-80), and the *Atlas Antiquus Major*, with its accompanying three volumes of *Geographie Ancienne* (1769).

Danzig (Polish *Gdańsk*), an important seaport and capital of West Prussia, and fortress of the first rank, is situated on the left bank of the western branch of the Vistula, 284 miles NE. of Berlin by rail, and about 4 miles from the river's mouth in the shallow Gulf of Danzig, an inlet of the Baltic. Danzig was an important town in the 10th century, and its possession was contended for by Danes, Pomeranians, Prussians, Brandenburgers, Poles, and the Teutonic Knights, the last of whom held it from 1308 to 1454, when it became a free city under Poland. In 1793 it fell to Prussia, in whose hands, except during the years 1807-1814, when it existed as a separate dukedom under Napoleonic rule, it has since continued. It is surrounded by a wall with twenty bastions, and by wet ditches, and possesses works for laying the surrounding country under water on three sides; its works are strengthened by outlying forts, and a chain of batteries extends to the mouth of the river. The city is traversed by the Motlau and Radauue, tributaries of the Vistula, the former of which has been deepened to 15 feet, and admits vessels up to the *Speicherinsel*, an island forming one of the quarters of the town, retained for the storage of grain. The principal port, however, is at the mouth of the Vistula, below the sand-bars across it. Many of the streets are narrow and crooked, but the *Langgasse*, intersecting it from east to west, presents a most picturesque appearance, with its lofty gable houses of the 16th

and 17th centuries; and there are good suburbs to the west, with wide thoroughfares. Among the most noteworthy buildings are the large church of St Mary (1343-1502), with a noble 'Last Judgment,' painted probably by Meniling, and a finely-carved altar of wood; the church of St Catharine (1326-30); the fine old Gothic town-hall; the old exchange; and the Franciscan monastery, now used as a museum and school. Danzig was at one time a prominent member of the Hanseatic League, and is still one of the chief commercial cities of northern Europe. Of the seaward trade in 1884, nearly £2,850,000 represented the imports (chiefly herrings, cotton, iron, drugs, coal, coffee, and hides), and £3,162,000 the exports (sugar, wheat, timber, spirits, &c.). The river and railway trade is also important. The manufactures include beer, spirits (Danzig *Goldwasser*), sugar, tobacco, flour, iron-ware, machinery, amber, gold and silver ornaments; and there are also an imperial dockyard employing 1580 men, and an artillery arsenal with over 800 workmen. The town has a library of 100,000 volumes, and is well supplied with hospitals, asylums, schools, museums, &c. Pop. (1880) 108,551; (1885) 114,805, of whom 77,878 were Protestants.

Daoudnagar. See DAUDNAGAR.

Daphne, a nymph who, chased by Apollo, changed herself into a laurel. The myth is a *point d'appui* of the solar mythologists. Daphne was the name of a famous grove of cypresses and laurels near Antioch, with a temple of Apollo.

Daphne, a genus of Thymelaeaceae, all shrubs or small trees, deciduous or evergreen, acrid and with poisonous berries, but often with deliciously fragrant flowers. The deciduous Mezereon (*D. Mezereum*), well known both for the fragrance of its pink winter flowers and for its medicinal uses, is naturalised in some places of England. The only species certainly a native of England is the Spurge Laurel (*D. Laureola*), an evergreen shrub, 3 to 4 feet high, with large, leathery, tufted leaves,

Daphne Cneorum.

and greenish-yellow axillary flowers. It grows well under the shade of trees, and flowers in February, while the nearly allied *D. pontica*, introduced from Asia Minor, flowers a month later. Upon the three species are grafted the rarer or less hardy species. Easily recognised by its trailing and branching habit, with persistent smooth, linear, obtuse, mucronate (box-tipped) leaves, and its fragrant profusion of terminal flowers in early spring, *D. Cneorum* is the best of all species for small gardens; while *D. alpina*, with its varieties *Dauphin* and *Verloti*, is a pretty deciduous form for rock-work.—*D. japonica*, from Japan, has lemon-scented leaves. From the bast of some species of Daphne, and nearly allied genera, useful fibre is obtained, and paper is made in different parts of the East, particularly *Nepal paper* from that of *D. cannabina*. In Tibet *Edgworthia Gardneri* is employed in the same way.

Daphnia. See WATER-FLEA.

Darabgherd, or DARAB, a town of Persia, in the province of Farsistan, 115 miles SE. of Shiraz. Pop. 4000. To the south lie the ruins of an older town of the same name.

Daraganj, a suburb of Allahabad, from which it is 2 miles distant, on the right bank of the Ganges. Pop. 13,159.

Darbhanga, the chief town of Darbhanga district, in Behar province, on the Little Bagmati River, 78 miles NE. of Patna by rail. It has large bazaars and a handsome market-place, extensive tanks, a hospital, and the maharajah's palace, with fine gardens, menagerie, and aviary. There is an active trade in oil-seeds, food-grains, timber, salt, iron, lime, &c. Pop. (1881) 65,955.—The district has an area of 3665 sq. m., forming one large alluvial plain, intersected by a network of streams, and covered with wide rice-fields, bamboo, and mango-groves. The rivets flood extensive areas, and fever is endemic. Rice, indigo, linseed, mustard, and tobacco are the chief crops; the manufactures include indigo, sugar, saltpetre, pottery, cloth, and tobacco. Pop. (1872) 2,139,298; (1881) 2,633,447.

D'Arblay, MADAME, better known as a novelist by her maiden name of Frances Burney, was born at King's Lynn, 13th June 1752, the second daughter and the third child of the six children of Dr Burney, then organist there. Her father removed to London to teach music in 1760, and on his wife's death next year sent his daughters Esther and Susannah to a school in Paris, but kept Fanny at home from a fear that her great affection for her maternal grandmother, then in France, should make her a convert to Catholicism. Dr Burney's second marriage in 1766 gave her a kind step-mother, but did not disturb her daydreams nor her incessant scribbling of stories, plays, and poems, begun at ten, although but two years before she was ignorant of her letters. On her fifteenth birthday, in a fit of repentance for such waste of time, she burned all her papers, but she could not erase from her brain the plot of the story which grew later into *Evelina*, or a *Young Lady's Entrance into the World*. This was sold for £20 to Lowndes, and published anonymously in January 1778, not even her father having seen the manuscript, although he had been dutifully told beforehand of the project. Dr Burney at once recognised his daughter's touch, and soon confided the secret to Mrs Thrale, who, as well as Dr Johnson, petted and flattered the gifted young authoress to her heart's delight. The praises showered upon the book by Johnson, Reynolds, Burke, and the whole world of fashion, might well have turned her head, and are told in delightful detail in her diary. Urged to write a comedy, she had the sense to suppress it in deference to the criticisms of her father and Samuel Crisp, a sagacious old critic, soured to the world but not to her, the 'daddy' of so many of her letters. In 1782 she published *Cecilia*, which was no less successful than her first novel. At Windsor, in the house of her friend the venerable Mrs Delany, she became known to the royal family, and soon received (July 1786) the appointment of second keeper of the robes at court, with a salary of £200 a year. She soon found her menial duties intolerably tedious, and her health began to decline, but her veneration for the queen kept her from resigning until compelled by the remonstrances of Burke, Boswell, Windham, and others of her father's friends. At length in July 1791 she was permitted to retire with a pension of £100 a year, and soon recovered her health and spirits by travelling in England. At Mickleham, near Dorking, she met General D'Arblay, a French refugee, and married him on nothing more than her pension in July 1793. Her third novel, *Camilla*, was published by subscription in 1796, and brought her, it is supposed, about 3000 guineas, with which she built Camilla Cottage, near Mickleham. It was, however, nothing more than a pecuniary success, while her tragedy, *Edwy and Elvina*, had already been damned in 1795, spite of the acting of Mrs Siddons and Kemble. From 1802 to 1812 she lived at Passy in France with her husband, who

had procured civil employment there, then returned to England with her son, tended her father till his death in April 1814, and in the beginning of the same year published her last novel, *The Wanderer*, another literary failure. At the first Restoration she joined her husband in Paris, was at Brussels during the battle of Waterloo, and soon after returned finally to England with her husband, who died 3d May 1818. Her son was tenth wrangler at Cambridge that year, took orders, became minister at Ely chapel in 1836, and died of rapid decline the year after. In 1832 Madame D'Arblay published her memoirs of her father, written in a strangely pretentious style, and died after a severe illness, 6th January 1840. Five volumes of her *Letters and Diaries* were published in 1842, the remaining two volumes in 1846. Spite of its tedious triviality this work is invaluable from the insight it gives us into the very heart of the dull decorous court of George III., and much more for its revelation of English manners towards the end of last century. Its stories of Dr Johnson and his group will live in literary history. Croker's ill-tempered attacks on her veracity for allowing an impression to go abroad that *Evelina* had been written at seventeen, printed in the *Quarterly Review* for April 1833 and June 1842, were satisfactorily answered by Macaulay in the *Edinburgh Review* for January 1843. As a novelist, Frances Burney's greatest merit is that she conceived the idea of representing modern society in a manner realistic without ceasing to be feminine and completely artistic. She was the forerunner of Miss Edgeworth and Jane Austen, who were both greater than herself. The latter's admiration for her model is imperishably written in a passage in *Northanger Abbey*.

Darboy, GEORGES, an ill-fated Archbishop of Paris, was born 16th January 1813 at Fayl-Billot, in Haute-Marne. He was educated at the seminary of Langres, and four years after his ordination as priest (1836) was appointed a professor there. In 1845 he came to Paris, where his reputation as translator of Dionysius the Areopagite had preceded him. In 1854 he was made protonotary apostolic, in 1859 Bishop of Nancy, and in 1863 Archbishop of Paris. He strenuously upheld the Gallican theory of episcopal independence, and waged a long struggle with the Jesuits that lost him the favour of the holy see. At the Vatican Council he opposed with vigour the declaration of the papal infallibility, but when the dogma was finally adopted, was one of the first to set the example of submission. During the German siege of Paris he was unceasing in labours of benevolence, and during the brief but dreadful triumph of the Commune he refused to leave his flock. Arrested as a hostage by the Communists, 4th April 1871, he was shot in the court of the prison of La Roquette on the 24th of May. He died with the heroic courage of the Christian martyr, words of forgiveness on his lips, and his hands lifted in blessing as he fell. His two immediate predecessors had likewise died a bloody death—Sibour murdered during the celebration of a religious rite (January 3, 1857); Affre shot down on the barricades (June 1848). Darboy's body was reinterred in a stately public funeral, 5th June 1871. See Fonlon's *Vie de Darboy* (1889).

Darbylites, a name often applied to the Plymouth Brethren (q.v.) from their principal founder, John Nelson Darby (1800–82), of whose collected writings thirty-two volumes have appeared (1867–83). See his *Personal Recollections* (1881).

D'Arc. See JOAN OF ARC.

Dardanelles (the ancient *Hellespont*), a narrow channel separating Europe from Asia, and uniting the Sea of Marmora with the Archipelago. The

name is derived from the ancient city of Dardanus in the Troad, on the southern shore; and Dardanus was named from the Dardani, an ancient people farther inland. The strait extends from north-east to south-west, and has a length of about 40 miles, and a breadth varying from 1 to 4 miles. From the Sea of Marmora a strong current runs through the strait to the Archipelago. Both sides are strongly fortified. A treaty concluded between the five great powers and Turkey in 1841 arranged that no ship of war belonging to any nation save Turkey should pass the Dardanelles without the express consent of Turkey; all merchant-ships being also required to show their papers to the Ottoman authorities. These provisions were confirmed at London in 1871 and at Berlin in 1878, in the February of which year a British fleet had sailed into the Sea of Marmora. The Dardanelles is celebrated in ancient history on account of Xerxes and Alexander having crossed it, the former in 480 B.C. to enter Europe; and the latter in 334 B.C. to enter Asia. The point at which Xerxes crossed, by two separate bridges, was in the neighbourhood of Abydos, on the Asiatic shore, opposite to Sestos. Alexander crossed at nearly the same place; and here also young Leander nightly swam across to visit Hero—a feat performed in 1810 by Lord Byron.

Dardanus, a son of Zeus and Electra, the mythical ancestor of the Trojans, and through them of the Romans. Originally a king in Arcadia, he migrated to Samothrace, thence to Asia, where King Teucer gave him the site of his town, Dardania. He married a daughter of Teucer, and his grandson was the eponymous hero Tros, who removed his grandfather's Palladium to Troy.

Dardistan is the name given to a region of Central Asia, bordering on Baltistan, the north-western portion of Cashmere. The country, which consists of lofty mountains and high-lying valleys, is little known, and its limits are variously given. But its interest depends mainly on the fact that its inhabitants, the Dards, are an Aryan people, speaking a Sanskritic tongue mixed with Persian words. They had been called 'Stray Aryans in Tibet,' and are Moslems converted from Buddhism at a comparatively recent period: the rajah of Cashmere is constantly endeavouring to subject them completely to his authority. The chief districts are Hasora, Gilgit, and Tassin; some would also include Chitral (q.v.) in Dardistan. See Leitner's *Results of a Tour in Dardistan* (Lond. 1867–70), and the Report of the Survey of India Department for 1883–84.

Dar-fertit is the name of the thinly-peopled territory south of Dar-Fâr, beyond the Bahr-el-Arab, and north of the Niam-Niam country. It has been desolated by the slave-trade. Schweinfurth was the first European to visit the region, which he traversed in 1870–71.

Dar-Fâr, a country of Central Africa, one of the divisions of the Sûdân or 'Land of the Blacks,' situated approximately in 10° to 16° N. lat., and in 22° to 28° E. long.; but its limits are not clearly defined. It is hilly in parts, and traversed by a mountainous ridge called Marra, which is the source of numerous streams. Towards the north it is level, sandy, and almost destitute of water. During the rainy season (June–September) it exhibits a rich vegetation. The principal products are wheat, millet, rice, maize, and sesame. Tobacco, which is used by the natives in every form, abounds. Water-melons, also, are abundant during the rainy season. Among the fruits are tamarinds and dates. The chief minerals are copper and iron. The wealth of the inhabitants consists principally in cattle. Horses, sheep, camels,

and game abound. Dar-Fûr carries on a considerable trade with Egypt, Mecca, and the inland countries of Africa; it was (and probably is again) a notorious centre of the slave-trade. The Fulahs are an intelligent, well-built race, and have long been Mohammedans: their numbers are variously estimated at from three to four millions. Dar-Fûr was annexed to Egypt in 1874-75, and the country organised into four provinces (Umshanga, Fasher, Dara, and Kabbabia). The residence of the governor was Fasher. Kobbe is the chief trading town. In 1884 Dar-Fûr fell under the power of the Mahdi, and is still subject to his successor the Khalif Abdallah. See EGYPT.

Dargan, WILLIAM, railway projector, was born at Carlow, 28th February 1799, spent some time in a surveyor's office, and for a time was employed under Telford. He was a successful contractor, and became one of the first capitalists in Ireland. It was he who in 1831 contracted for the first railway ever executed in Ireland (the Dublin and Kingstown), and he was afterwards connected with most great Irish undertakings, such as the making of railways, canals, tunnels, and embankments. He was also an extensive holder of railway stock, a steamboat proprietor, flax-grower, farmer, and the main promoter of the Dublin exhibition of 1853, when he declined a baronetcy. He died 7th February 1867.

D'Argens, JEAN BAPTISTE DE BOYER, MARQUIS, born at Aix, in Provence, 1704, at the age of fifteen entered the army, but disabled in 1734 by a fall from his horse, and disinherited for his follies, he went to Holland and tried his fortune in authorship. Frederick the Great, then crown prince of Prussia, was attracted by his writings, and on his accession invited him to the court of Prussia. The king appointed him chamberlain and a director of the fine arts. When almost a sexagenarian he renewed the adventures of his youth by again falling a victim to the charms of an actress, whom he married without Frederick's permission. Deprived of his pension, he returned to Provence, and died near Toulon, 1771. His works fill 38 volumes. See his *Mémoires* (new ed. Paris, 1807).

D'Argenson, MARC PIERRE, COMTE, a celebrated French statesman, was born in 1696, the younger son of the Marquis d'Argenson (1652-1721) who created the secret police and established the *lettres de cachet*. After holding a number of inferior offices, he became war minister in 1743, at a time when the very political existence of France was imperilled, and by his vigour and lucky choice of generals changed the fortunes of the war in the course of a single year. After the peace of Aix-la-Chapelle (1748), he devoted himself to the improvement of the military system, and in 1751 established the *École Militaire*. He was an illustrious patron of literature. Diderot and D'Alembert dedicated to him their great *Encyclopédie*; and to Voltaire, whose fellow-student he had been, he furnished materials for his *Siècle de Louis XIV.* In 1757 he was banished to his estate by the machinations of Madame Pompadour; but on her death he returned to Paris, where he died in 1764.

Daric, a Persian gold coin named after Darius, weighing 128 grains; it was probably worth £1, 1s. 10d.

Darien, a name formerly applied to the entire isthmus now generally known as Panamá (q.v.). It is now more properly confined to the heavily-wooded hill-country lying between the Gulfs of Uraba on the north and San Miguel on the south. The former, a principal inlet of the Caribbean Sea, is commonly called the Gulf of Darien; and the Colombians distinguish San Miguel as the Darien of the South. The southern extremity of the

northern gulf forms the Bay of Choco, into which the river Atrato (q.v.) debouches; the southern gulf receives the Tuira, after a course of 190 miles, of which over 100 are navigable. Little of the district, which is rich in gold, has yet been explored. There is, however, an active trade in tortoiseshell, pearls, and gold-dust, which the Indians readily barter for firearms and rum. These natives are said to number 20,000, are uncivilised, and as expert with the gun as were their ancestors with the bow. The capital of the district is Yaviza (3000 inhabitants).

Darien Scheme, a disastrous speculation projected by William Paterson (q.v.), the founder of the Bank of England, was established by act of the Scottish parliament, and was sanctioned by royal authority in 1695. Its object was to plant a colony on the Atlantic side of the Isthmus of Panamá, and so form a commercial entrepôt between the eastern and western hemispheres. An entire monopoly of the trade of Asia, Africa, and America, for a term of thirty-one years, was granted to the Company. At that time, the foreign trade of Scotland had been ruined by the English Navigation Act of 1660, which provided that all trade with the English colonies should be conducted in English ships alone, so that when Paterson opened his subscription-list, the nobility, the gentry, the merchants, and people, royal burghs, and public bodies in Scotland all hastened to subscribe. No less than £400,000 was immediately put down on paper, of which £220,000 was actually paid up. Deputies in England received subscriptions to the amount of £300,000; and the Dutch and Hamburgers subscribed £200,000. The English parliament, however, actuated by a feeling of national antipathy, and the jealous clamours of trading corporations, gave its unequivocal condemnation to the scheme. The British resident at Hamburg, probably with the concurrence of William III., also made various insinuations against it. The result of this interference was the almost total withdrawal of the Dutch and English subscriptions. It must now be admitted that there was one fatal objection to the scheme—viz. the danger of settling on ground claimed by Spain, without coming to a proper understanding with that country beforehand. Unable, however, to see any sort of obstacles, incited by the vehement eloquence of Paterson, and dazzled by the magnificent proportions of the scheme, the Scotch hurried forward their arrangements. Five ships, with 1200 men on board, set sail from Leith for Panamá on the 25th July 1698. They reached their destination in four months, near what is still called Puerto Escoce (in 8° 50' N. lat.), and having bargained with the natives for a country which they called New Caledonia, the colonists fixed the site of what was to be their capital, New Edinburgh, and built a fort in its vicinity, which they named New St Andrews. Having thus constituted their colony, they issued a proclamation of perfect freedom of trade and universal toleration in religious matters to all who should join them. For the first few months they seemed to be on the highway to success. But the climate, which was tolerable in winter, became unbearable in summer, and many sickened under it; their supplies failed before they could derive a return from the soil; and on sending to the British colonies in America for provisions, they learned with the deepest indignation and despair that the British American colonies, having been informed that King William had not given his sanction to the expedition, had resolved to hold no intercourse with the new colony at Panamá.

Sickly and desponding, they waited long for supplies from the mother-country; but the Company at home was not aware of their wretched

condition, and none came. At length, having waited eight months for assistance, the colony broke up. In the meantime, 1300 colonists had set sail from Scotland, but ere they arrived the pioneers had fled. A Spanish force of 1500 men, and a squadron of 11 ships, immediately threatened the new-comers. Captain Campbell marched by night with a body of 200 Scots upon the Spanish camp, which he broke and completely dispersed. On returning to the fort, however, he found it invested by the Spanish squadron. The ammunition of the colonists had now become exhausted, and they were obliged to capitulate, the Spaniards granting honourable terms. Not more than thirty of the colonists, among whom was Paterson, who was rendered for a time insane by his dreadful misfortunes, ever reached Scotland. The collapse of the scheme caused unprecedented excitement in Scotland from 1695 till 1703, when the last of the adventurers reached home, and contributed to render the union of the kingdoms highly unpopular. It has been fairly contended that, but for the hostility of the king and the jealousy of the English companies, the scheme might have led to enormous extension of British commerce and British territory. And it should be remembered that a Panama Canal was included in the plans of the far-seeing projector. The books and other documents which had belonged to the Company are preserved in the Advocates' Library; the most complete account of the scheme is J. H. Burton's *Darien Papers*, printed by the Bannatyne Club (1849). See also his *History of Scotland*, vol. viii., and Warburton's novel *Darien*.

Darius (*Dāryavus*, Heb. *Dārēyāvesh*), the name of three kings of Persia. **Darius I.** (*Hystaspis*), born in 548 B.C., was the son of Hystaspes (Vistāspa, in the Babylonian cuneiform *Ustaashpi*), of the family of the Achaemenides (q.v.), and succeeded to the Persian throne in 521, after putting to death the Magian Gaumātā (the Pseudo-Smerdis of the Greeks), who gave himself out to be Bardes, brother of Cambyzes. We possess accurate accounts of his reign through a contemporary monument, the great trilingual inscription on the rock of Behistun (q.v.). He is there represented with his foot on the body of Gaumātā, and with nine conquered rebels in front of him, the first three from Susiana, Babylon, and Media, the ninth a Scian, with the characteristic pointed hat mentioned in Herodotus, vii. 64. The inscription states that his father, Hystaspes, was the great-grandson of Teispes, who was the son of Achaemenes. Darius had for several years to contend with revolts in all parts of his empire. Babylon resisted him with especial obstinacy under Nidinta-Bel for nearly two years (520-19), and revolting a second time, under Arakha, was again taken (514). He then reorganised the Persian empire, removing the seat of government to Susa, dividing his dominions into more than twenty satrapies, establishing a regular system of taxation, and providing facilities for communication and trade; while he also pushed his conquests as far as the Caucasus and the Indus. The Indian province paid into the exchequer £1,290,000 a year; Babylonia, £290,000; while other eighteen satrapies contributed altogether £1,674,000. In his expedition against the Scythians in 515, after carrying 700,000 men across the Bosphorus on a bridge of boats, and subduing Thrace and Macedonia, he was led on by the retreating Scythians as far as the Volga, and returned to the Danube with the loss of 80,000 of his warriors. He returned to Susa, leaving Megabazos in Thrace with a large part of his army. His first expedition against the Athenians miscarried through the wreck of his fleet at Mount Athos in 492; the

second was decisively defeated at Marathon (q.v.) in 490. He died in 485, before the Egyptian revolt (487) had been subdued, and in the midst of his preparations for a third expedition against the Athenians, and was succeeded by Xerxes (q.v.). Darius was a Persian by birth, and bred in the Zoroastrian faith, which under him and his successors became the state religion of the empire. He is mentioned in the Old Testament as permitting (520) the erection of the second temple at Jerusalem, which was completed in the sixth year of his reign (515).

Darius II. (*Ochus*, called by the Greeks *Nothos*, 'bastard'), illegitimate son of Artaxerxes I., in 424 B.C. snatched the crown from Sogdianus, his also illegitimate brother, who had put to death the rightful king, Xerxes II. He was entirely under the influence of the eunuchs and women of his harem, especially his cruel and depraved aunt and spouse Parysatis; and his reign was a long series of miseries and crimes. The numerous revolts were cruelly put down, except that of Amyrtæus, satrap of Egypt, who was independent from 414 to his death in 408. After the failure of the Sicilian expedition of the Athenians in 415, Darius seized the opportunity to break the humiliating treaty of 449. Through Tissaphernes, satrap of Asia Minor, and his successor Cyrus, younger son of Darius and Parysatis, he gave so much support to the Spartans against the Athenians in the Peloponnesian war as turned the scale to the side of the former. He died at Babylon in 405, and was succeeded by his eldest son, Artaxerxes II.

Darius III. (*Codomannus*), the last king of the Persians, son of the Achaemenid Arsanes by Sisymbis, daughter of Artaxerxes II. (q.v.). He is briefly designated as 'Darius the Persian' in Nehemiah, xii. 22, and in the 1st Book of Maccabees is called 'King of the Persians and Medes.' Artaxerxes III. had been poisoned by Bagoas in 338, and the speedy death of his son and successor, Arses, prepared the way for Darius III., who began to reign in the same year as his conqueror Alexander the Great (336). Defeated at the Granicus (334), at Issus (333), and at Arbela (331), the handsome and gentle king was betrayed and slain during his flight by one of his satraps (330). See ALEXANDER THE GREAT.

DARIUS THE MEDE, mentioned in the Book of Daniel, cannot with certainty be identified with any historical king.

Darjeeling (*Dārjiling*), a sanitary station in the Lower Himalayas, and administrative headquarters of Darjeeling district, is situated on a narrow ridge, at an elevation of 7167 feet above the sea. It has a fine sanatorium (1883), a good water-supply, and is an increasingly popular summer-resort for visitors and invalids. The fashionable month is October, after the rains, when the clear atmosphere shows at its best a view of unsurpassed extent and grandeur. Pop. 7018.—**DARJEELING** is the most northerly district of the Kuch Behar division of Bengal, divided from Independent Sikkim by a series of rivers and mountain-torrents. Area, 1234 sq. m. Pop. (1872) 94,712; (1881) 155,179, mostly Nepalis and other aboriginal or semi-aboriginal tribes, attracted to the district by the increased demand for labour on the railway and in the tea-gardens. With a surface divided between the Lower Himalayas and the marshy sub-montane strip, the scenery of the district is magnificent; up to 12,000 feet the ridges are clothed with valuable forests, and on the higher slopes the rhododendron grows in gorgeous luxuriance. The climate is excessively humid, but not unhealthy. Food-crops are raised, and there is a trade with Tibet and Nepal; but the staple industry is the cultivation of tea, of which the

yield in 1883 was 8,080,293 lb. See the Report of the Indian Survey for 1883-84.

Dark Ages. See AGE.

Darley, FELIX O. C., an eminent American artist, was born at Philadelphia, Jan. 23, 1822. He early gave himself to drawing with such success as to encourage him to devote himself exclusively to art, especially in the form of book illustration. His earliest important work was a series of drawings for the *Library of Humorous American Works*, after producing which he went to New York (1848), where his outline drawings to Washington Irving's *Legend of Sleepy Hollow* and *Rip Van Winkle* soon spread wide his reputation. Later works, not less popular, are his illustrations of Judd's *Margaret*, and to Cooper's, Dickens's, and Simms's novels. In 1868, after some years' residence in Europe, he published both illustrations and letterpress of *Sketches Abroad with Pen and Pencil*.

Darling, a name applied to a river, a mountain-range, and two districts in Australia, is derived from Lieutenant-general Sir Ralph Darling (1775-1859), who was governor of New South Wales (1825-31). (1) The river Darling, a tributary of the Murray River, is formed by the union of several head-streams, all of which rise in the great Dividing Range. The chief of these head-streams are the Barwon and Gwydir. Farther down, the Darling receives the Culgoa and the Warrego from the north, and the Bogan from the south. Its length, with affluents, is stated at 1160 miles, and it and its tributaries are estimated to drain an area of 198,000 sq. m. It joins the Murray at Wentworth, on the border between New South Wales and South Australia, having received no tributary in its lower course. Much of the district traversed by it is an arid plain, save near the river-bank; the river is subject to floods. (2) The Darling Range, in Western Australia, runs parallel to the west coast, at a distance of 10 to 25 miles inland, from the south-west corner of the colony to a point some 250 miles farther north. The range has a height of from 1500 to 2000 feet; and in Mount William attains an elevation of 3000 feet. (3) The Darling district at the south-western corner of New South Wales, scantily watered, has an area of 50,000 sq. m. (4) The Darling Downs form the richest pastoral district of Queensland, in the southern part of the colony. This is an upland district on and about the summit of the Dividing Range. It was discovered by Allan Cunningham, the botanist, in 1827, and has an area of 6080 sq. m. There is also much fine agricultural land in which the cereals, potatoes, and all kinds of vegetables grow well. The western railway traverses the north, and the southern line the extreme east of this district.

Darling, GRACE, a name famous in the annals of heroism, was the daughter of William Darling (1795-1860), lighthouse-keeper on Longstone, one of the Farne Islands, and was born at Bamborough, 24th November 1815. On the morning of the 7th September 1838, the *Forfarshire*, bound from Hull to Dundee, with sixty-three persons on board, struck the Harker's Rock, among the Farne Islands, and in fifteen minutes forty-three persons were drowned. The vessel was seen by Grace Darling from the lighthouse at a quarter to five lying broken on the rocks. Darling and his daughter agreed that if they could get to her, some of the shipwrecked crew would be able to assist them in getting back. By wonderful strength and skill, they brought their boat to where the sufferers (nine in number) crouched. The solitary woman and four men were safely taken to the Longstone; two of the men returned with Darling, and succeeded in bringing the remainder

off by nine o'clock A.M. Such an undertaking, so daring in itself, and so successfully carried out, filled every one with the warmest admiration. The lighthouse at Longstone, solitary and unknown no more, was visited by many of the wealthy and the great. Presents, testimonials, and money were heaped at the feet of Grace Darling; but she did not long survive her change of circumstances. She died of consumption, after a year's illness, on 20th October 1842. See *Grace Darling*, by E. Hope (1876), and the *Journal of William Darling* (1886).

Darlington, a parliamentary and municipal borough in the south of the county of Durham, on a slight elevation overlooking the Skerne near its junction with the Tees, 23 miles S. of Durham, and 45 NNW. of York. The chief industry of the place is connected with the extensive locomotive works, which give employment to many workers. There are iron and steel works in the north end of the town; brewing and tanning are carried on; and there are wool-mills. Pop. (1821) 6551; (1851) 11,228; (1871) 27,730; (1881) 35,102, of whom many are connected with the Society of Friends, long a prominent and influential element amongst the inhabitants. Darlington was created a parliamentary borough, sending one member to parliament, in 1867. Its prosperity dates from the opening, on 27th September 1825, of the Stockton and Darlington Railway, which was the first passenger-line on which a locomotive-engine was employed; and that locomotive now stands on a pedestal outside the station. From the 11th century onwards the town belonged to the bishops of Durham, and till 1867 a borough bailiff, appointed by the bishop, managed its affairs; in that year it obtained a charter of incorporation. St Cuthbert's collegiate church, a very fine specimen of Early English, was founded in 1160 by Bishop Pudsey, and was restored by Sir G. G. Scott in 1869. It has three beautiful sedilia, and a tower 180 feet high. Among the chief modern erections are the other churches (Anglican, Presbyterian, Roman Catholic, and Non-conformist), the spacious new railway station (1887), a grammar-school, a high school for girls, a British and Foreign School Society's college for female teachers, and the banks of Backhouse & Co., and Pease & Co. A free library was opened in 1885, for which Mr Edward Pease had bequeathed £10,000. At Oxen-le-field, 3 miles from Darlington, are curious cavities of unknown origin, called Hell Kettles; and near Darlington was the seat of George Allan the antiquary (1736-1800).

Darlingtonia, a genus of remarkable American Pitcher-plants, belonging to the family of Sarraceniacæ (q.v.); and like its congeners, is insectivorous. See INSECTIVOROUS PLANTS.

Darmstadt, a town of Germany, capital of the grand-duchy of Hesse-Darmstadt, is situated on the small river Darm, 15 miles S. of Frankfort-on-Main. The streets of the old town are narrow, but those of the new town exhibit many imposing specimens of architecture. Darmstadt has several public squares, and fine public gardens and promenades. Besides the arsenal, the barracks, and the various religious edifices, it possesses two palaces. One of these, the old ducal palace, contains museums of painting, natural history, and archaeology, and a library of 500,000 volumes; in the other, Prince Charles's palace, is Holbein's famous 'Meyer Madonna.' The handsome post-office dates from 1881, the theatre from 1871. There are manufactures of chemicals, hats, machinery, tobacco, playing-cards, carpets, and beer; and a trade in iron, petroleum, fruit, flour, and wine. But the place depends more on its ducal court and government offices than on

its industries. Pop., with suburb (1875), 44,088; (1885) 51,323.

Darnel (*Lolium temulentum*), an annual grass of the same genus with the valuable Rye-grass (q.v.)—from which it may be distinguished by the absence of the perennial rootstock, by the empty glume, equalling or exceeding the five to seven (instead of eight to fifteen) flowered spikelet, and the awn long instead of short, or absent—is common in corn-fields in England and many parts of Europe. It is the tares of the parable, and has from ancient times been reputed to have a narcotic poisonous seed, to which many bad effects were ascribed, which, in years of bad harvest, were observed to ensue upon the eating of bread or the feeding of horses upon oats. The poisonous properties have been denied by some botanists, and again maintained by others, the most recent investigations on the whole confirming the ancient view. The seed may lie in the ground for several years without germinating, and then appear suddenly in great quantity in a wet season. It can, however, be eaten by cattle with impunity.

Darnétal, a town in the French department of Seine-Inférieure, 2½ miles E. of Rouen, with manufactures of cotton, linen, and cloth goods. Pop. 6532.

Darnley, HENRY STEWART, LORD, husband of Mary, Queen of Scots, was the eldest son of the Earl of Lennox by Lady Margaret Douglas, so a grandson of Margaret Tudor, and a cousin of Mary. Born in 1546, in England, where also he was educated, he was handsome in appearance, accomplished in manners, but fatally destitute of all moral and intellectual power. He perished by a gunpowder explosion at Kirk-of-Field, Edinburgh, 10th February 1567. Darnley is interesting chiefly on account of the position which he occupied with respect to his wife. See MARY, QUEEN OF SCOTS.

Darter (*Plotus*), a genus of birds nearly allied to Cormorants (q.v.), but very heron-like in gait and gesture. The four species are severally restricted to the warm parts of America, Africa,

Darter (*Plotus anHINGA*).

Asia, and Australia. The head is small, with naked cheeks and throat; the neck is very long, thin, and flexible; the bill is long and straight; the tail and the toes are also long. The darters catch fish voraciously and with great dexterity; the name 'snake-neck' well describes them.

Though aquatic in habit, they rest and nest on trees. The American species figured is over three feet in length.

Dartford, a thriving market-town of Kent, in the narrow valley of the Darent, 2 miles above its influx to the Thames, and 17 ESE. of London. Edward III. here founded an Augustinian nunnery (1355); St Edmund's chantry was a great place of pilgrimage; and at Dartford Wat Tyler commenced his rebellion (1381). The church, with a Norman tower, was restored in 1863; among its interesting monuments is one to Sir John Spielman, Queen Elizabeth's jeweller, who in 1588 established at Dartford what is said to have been the first paper-mill in England. Paper is still manufactured, besides steam-engines and machinery, gunpowder, &c. The modern buildings include a county courthouse (1859), assembly rooms (1860), and, in the neighbourhood, the City of London lunatic asylum (1866). Pop. of parish (1851) 6224; (1881) 10,163. See the local histories by Dunkin (1844) and Bayly (1876).

Dartmoor is a great granitic upland in Devonshire, the source, with two exceptions, of all the principal rivers of the county, remarkable alike for its wild and rugged scenery, its antiquities, its wide, solitary, trackless wastes, and its mineral products. It is upwards of 130,000 acres in extent, the extreme length from north to south being 25 miles, and the extreme breadth from east to west 20 miles. The outline is irregular. The central portion is the ancient royal forest of Dartmoor, and this is surrounded by a belt of open country, once known as the 'Commons of Devonshire,' but portions of which have been inclosed. The attempts to cultivate Dartmoor itself have been very few, and the northern quarter for miles shows no trace of man, but the valleys through which the rivers descend to the lowland country are singularly fertile, and at times full of beauty. The moor itself affords valuable mountain pasture to cattle, sheep, and large numbers of half-wild ponies. The forest rights belong to the duchy of Cornwall; but there are rights of pasture exercised by holders of what are called venville tenures in certain parishes bounding the moor, which date prior to the Norman Conquest.

The average height of Dartmoor above the sea is upwards of 1200 feet, but its highest point, High Willhayes, is 2039 feet; and the next, Yes Tor, 2030. The hills are commonly called *tors*, and for the most part have granite crests, weathered into grotesque and picturesque shapes. The whole of Dartmoor is of granite, protruded between the close of the Carboniferous and the opening of the Triassic periods. Devonian rocks mantle round its southern extension, and Carboniferous round its northern, associated at various points with gabbros, dolerites, and other intrusive rocks. The granite is chiefly gray, but there are rich red varieties, as at Trowlesworthy. Large quantities of the ordinary stone have been quarried, especially at Hey Tor and King Tor. Dartmoor is rich in minerals. Tin has been raised for many centuries, long before the dawn of history, by streaming in the valleys, and vestiges of the ancient mining operations of the 'old men' abound. Copper, iron, and manganese have also been worked, but mining is now carried on at a few points only. Gold has frequently been found in the river-beds. The tinners of Devon had a quasi-corporate existence in Saxon times, and their rights were confirmed by King John and other monarchs. The Stannary Parliaments, in which they managed their affairs, were held in the open air on Crockern Tor. The most important mineral product of Dartmoor at the present day is china-clay, or kaolin, which is the result of the decomposition of the felspar

of the granite. The largest china-clay works in England are at Lee Moor, and are connected by a tramway with wharves at Plymouth.

The fauna and flora of Dartmoor have many points of interest. Trees are very rare; but there is a very singular group of gnarled and stunted oaks on a slope overlooking the West Dart, near Crockern Tor, of high antiquity and weird aspect, which has been called one of the 'wonders of the moor'—'Wistman's Wood.'

The chief rivers rise at a height of over 1800 feet above the sea, in a wide stretch of peat-bog around Cranmere Pool—the Dart, Teign, Taw, Okement, Lyd, Tavy, and Walkham. From the morasses of the southern quarter spring the Plym, Yealm, Erme, and Avon.

Dartmoor is unrivalled in England in the extent and character of its prehistoric and rude stone antiquities—earthworks, barrows, kistvaens, menhirs, lines or avenues, cyclopean bridges, circles, cromlechs, trackways, and pounds or inclosures of stones, sometimes containing the remains of villages. Many stone implements have been found. On several of the tors there are rock basins, formerly called Druidical, but now assigned to the operation of natural causes.

The chief centre of population is Prince Town, named after George IV. when Prince Regent. Here a prison was built (1806) during the war with Napoleon, for the reception of prisoners of war. When the war ended it was abandoned, and was at one time used for the manufacture of naphtha from peat, which failed, as all attempts to utilise the Dartmoor peat beyond the supply of local wants have done. In 1855 the buildings were adapted to their present purpose of a convict prison. Attached is a fertile reclaimed farm. A very picturesque railway runs to Prince Town. See the Rev. S. Rowe's *Perambulation of Dartmoor* (1856).

Dartmouth, a seaport and municipal borough (till 1867 also parliamentary) in the south of Devonshire, 32 miles S. by W. of Exeter. It is built in picturesque terraces on a steep slope 300 to 400 feet high, on the right bank of the romantic estuary of the river Dart, at a short distance from the sea. The streets are narrow, and many of the houses very old, with overhanging stories, projecting gables, and wood-carvings. St Saviour's Church (circa 1372) has a richly sculptured, painted, and gilt stone pulpit, and a beautifully carved rood-loft. A battery, and the remains of a castle built during the reign of Henry VII., stand at the entrance to the harbour. Pop. (1881) 5580. Dartmouth is a quarantine port of the English Channel, and has a considerable trade with the Mediterranean, and in the Newfoundland fisheries. It is the port of departure of the 'Castle' line of mail steamers to South Africa, and a favourite yachting station—the harbour being deep and landlocked. At Dartmouth, in 1190, the Crusaders, under Richard Cœur-de-Lion, embarked for the Holy Land. The French burned it in Richard's reign, but were repulsed, chiefly by the women, in an attack in 1404. In 1346 Dartmouth furnished 31 ships for the siege of Calais. In 1643 Prince Maurice besieged and garrisoned it; but in 1646 Fairfax stormed and took it. Newcomen, the inventor of the steam-engine, was born here; Sir Humphrey Gilbert was born at Greenway, on the opposite side of the Dart; and another great Elizabethan worthy, John Davis, at Sandridge.

Daru, PIERRE ANTOINE, COMTE, a French writer and financier, was born at Montpellier, 12th January 1767. At sixteen he entered the army, and rose rapidly, but was flung into prison during the Terror, where he amused himself by translating Horace. Under Napoleon he was Intendant-

general in Austria and Prussia, and a councillor of state, while in 1818 Louis XVIII. made him a peer. Thenceforth he devoted himself exclusively to letters. He died a member of the Institute and of the Academy of Sciences, 5th September 1829. Of his many books the chief are *Cléopâtre, ou Théorie des Réputations Littéraires* (1800), a spirited poem; *Histoire de la République de Venise* (7 vols. 1819-1821); and *Histoire de la Bretagne* (3 vols. 1826).—His son, NAPOLEON DARU, born at Paris, 11th June 1807, opposed the *coup d'état*, and was proscribed; but became a member of the National Assembly in 1871, of the senate in 1876.

Darwen, a municipal borough of Lancashire, on the river Darwen, $\frac{3}{4}$ miles S. of Blackburn, and 9 N. of Bolton. Cotton is the staple manufacture; then come paper-making and paper-staining; and to these and other industries, with its water facilities, and the neighbouring coal-mines and stone quarries, Darwen owes its rapid growth and its well-being. It was incorporated in 1878. Among the chief buildings are the free library, the market hall, the co-operative hall, and the public baths, erected in memory of Sir Robert Peel. Pop. (1851) 7020; (1881) 29,744.

Darwin, CHARLES ROBERT, F.R.S., naturalist, the discoverer of the principle of natural selection, was born at Shrewsbury, February 12, 1809. His grandfather was Dr Erasmus Darwin, and his father Dr Robert W. Darwin, F.R.S. His mother was a daughter of Josiah Wedgwood, the celebrated potter. Darwin was educated at Shrewsbury grammar-school, studied at Edinburgh University for two sessions in 1825-6-7, and entered at Christ's College, Cambridge, in 1828. Already at Edinburgh he had become a member of the local Plinian Society; he took part in its natural history excursions, and read before it his first scientific paper—a new contribution to our knowledge of the Flustra or sea-mats. It was at Cambridge, however, that his biological studies seriously began. Here he became acquainted with Professor Henslow, the well-known botanist, who encouraged his interest in botany and zoology. His chief taste at this time was for geological research. In 1831 he took his degree of B.A., and shortly after was recommended by Henslow as naturalist to the expedition of H.M.S. *Beagle*, under Captain (afterwards Admiral) Fitzroy, R.N., then about to start for a scientific survey of South American waters. He sailed on December 27, 1831, and did not return to England from his long cruise till October 2, 1836. Meanwhile he visited Teneriffe, the Cape de Verde Islands, the Brazilian coast, Monte Video, Tierra del Fuego, Buenos Ayres, Valparaiso, and the Chilean region, the Galapagos Archipelago, Tahiti, New Zealand, Tasmania, and the Keeling Islands, in which last he laid the foundation for his famous theory of coral reefs. It was during this long expedition that Darwin obtained that intimate knowledge of the fauna, flora, and geological conditions of many tropical, subtropical, and temperate climates which so admirably equipped him at last for the great task he was afterwards to perform in settling the factors of biological evolution.

On his return to England in 1836, he set to work to co-ordinate the results obtained during his voyage. He formed the friendship of Sir Charles Lyell and other scientific leaders, by whose aid he was appointed secretary of the Geological Society in 1838. A year later, he was elected to the fellowship of the Royal Society, and early in 1839 he married his cousin, Miss Wedgwood. In the same year he published his *Journal of Researches into the Geology and Natural History of the various Countries visited by H.M.S. Beagle*. From 1840 to 1843 Darwin was occupied with the publication of the *Zoology of the*

Voyage of the Beagle, under government auspices, to which great work (compiled by the leading specialist authorities of the day) he himself contributed an introduction and many notes. In 1842 appeared his work on *The Structure and Distribution of Coral Reefs*; in 1844, *Geological Observations on Volcanic Islands*; and in 1846, *Geological Observations on South America*. These works placed him at once in the front rank of contemporary scientific thinkers. In 1851-53 appeared his valuable treatise on barnacles, *A Monograph of the Cirripedia*.

Three years after his marriage Darwin settled at Down, near Beckenham, in Kent, where for the rest of his days he passed his time as a country gentleman among his conservatories, his pigeons, his garden, and his fowls. The practical information thus gained (especially as regards variation and interbreeding) was of invaluable use to him in his later researches. Private means enabled him to devote himself unremittingly henceforth, in spite of continuous and distressing ill-health, to the pursuit of science. It was at Down that Darwin began to occupy himself with the great work of his life—the problem of the origin of species. In 1837 he had already set out to accumulate facts and observations for this purpose. After five years' unremitting work, he 'allowed himself to speculate' on the subject, and drew up some short notes, which he enlarged in 1844 into a sketch of conclusions for his own use. These conclusions embodied in embryo the famous principle of natural selection, the germ of the celebrated Darwinian Theory (q.v.). With constitutional caution, however, Darwin delayed publication of his hypothesis, which was only at length precipitated many years later by an accidental circumstance of a romantic character. In 1858 Mr Alfred Russell Wallace, the distinguished explorer, sent home from the Malay Archipelago a memoir addressed to Darwin himself, for presentation to the Linnean Society. On opening this packet, Darwin found to his surprise that it contained in essence the main idea of his own theory of natural selection. Sir Charles Lyell and Sir Joseph Hooker, to whom he communicated the facts, persuaded Darwin to read a paper of his own concomitantly with Wallace's before the Linnean Society, which was accordingly done on July 1, 1858. Urged forward by this strange coincidence, Darwin set to work seriously at once to condense his vast mass of notes—the labour of a lifetime—and put into shape his great work on *The Origin of Species by means of Natural Selection*, published in November 1859. For an account of the main ideas there promulgated, see DARWINIAN THEORY. The book itself, an epoch-making work, was received throughout Europe with the deepest interest, was violently attacked and energetically defended, but in the end succeeded in obtaining recognition (with or without certain reservations) from almost all competent biologists. From the day of its publication Darwin continued to work on unremittingly at a great series of supplemental treatises, in which his main principles were still further enforced and enlarged, while minor corollaries were brought prominently into view. *The Fertilisation of Orchids* appeared in 1862, *The Variation of Plants and Animals under Domestication* in 1867, and *The Descent of Man* in 1871. The last-named work, hardly less famous than the *Origin of Species*, derives the human race from a hairy quadrumanous animal belonging to the great anthropoid group, and related to the progenitors of the orangutan, chimpanzee, and gorilla. In this book Darwin also developed his important supplementary theory of sexual selection, which on the whole has been received by scientific thinkers with less favour than his other ideas. His later works are *The*

Expression of the Emotions in Man and Animals (1873), *Insectivorous Plants* (1875), *Climbing Plants* (1875), *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* (1876), *Different Forms of Flowers in Plants of the same Species* (1877), and *The Power of Movement in Plants* (1880). His last work, *The Formation of Vegetable Mould through the action of Worms*, appeared in 1881. In it Darwin showed grounds for believing that the vegetable mould which covers a large part of the globe is mainly due to the castings of earth-worms, without which the greater portion of the land surface of the world must necessarily consist of barren rock or thirsty sand.

It is, however, as the great leader of evolutionary biology that Darwin will be mainly remembered among men. Though not (as is commonly, but erroneously, believed) himself the originator of the evolution hypothesis, nor even the first to apply the conception of descent with modification to plant and animal organisms, Darwin was undoubtedly the first thinker to gain for that conception a wide acceptance among biological experts. By adding to the crude evolutionism of Erasmus Darwin, Lamarck, and others, his own specific idea of natural selection, he supplied to the idea a sufficient cause, which raised it at once from the level of a hypothesis to the grade of a verifiable theory. His kindliness of character, honesty of purpose, devotion to truth, and attachment to his friends, rendered him no less remarkable on the moral and emotional than on the purely intellectual side of his nature. For many years his health had been extremely feeble, and he had worked under the severest physical disadvantages. He died suddenly, after a very short illness, April 19, 1882, and was buried with unusual honours in Westminster Abbey. See his *Life and Letters* by his son, Francis Darwin (1887).

Darwin, ERASMUS, physician, natural philosopher, and didactic poet, was born 12th December 1731, at Elston Hall, near Newark, in Nottinghamshire; entered St John's College, Cambridge, in 1750, graduated B.A. in 1754, and afterwards studied medicine at Edinburgh. After an unsuccessful attempt to establish a practice at Nottingham, he removed to Lichfield, where he married and became a popular physician and prominent figure from his ability, his radical and free-thinking opinions, his poetry, his eight-acre botanical garden, and his imperious advocacy of temperance in drinking. After his second marriage in 1781, he settled in Derby, and then at Breadsall Priory, where he died suddenly 18th April 1802. Darwin had once a great reputation as a physiologist, but his system is, for the most part, inconsequential, baseless, and untenable. At the same time, many of his ideas are original, suggestive, and contain within them the germs of important truths. His strength and his weakness lay in his faculty for seeing analogies in nature. Sometimes he is exceedingly happy in his discoveries; at other times he is quite fantastical. The same remarks hold good as regards his verse, where, amid the frequent extravagance and incomprehensibility of his notions, there burst forth strains of genuine poetry. *The Loves of the Plants* (1789), a part of his chief poem, the *Botanic Garden*, was happily burlesqued in the 'Loves of the Triangles' in the *Anti-Jacobin*. Interest in Darwin's speculations has been revived by the recognition of his partial anticipation of Lamarck's views on evolution, and so of his own famous grandson's. His chief works are *Zoönomia, or the Laws of Organic Life* (1794-96); and his *Phytologia, or Philosophy of Agriculture* (1799). See his *Life* by Krause, trans. by Dallas (1879). By his first wife he was grandfather of Charles Darwin; by his second, of Francis Galton.

Darwinian Theory, the explanation of the evolution of forms of life on our planet, offered by the great naturalist, Charles Darwin (q.v.). From the very outset we must carefully guard against the confusion, still widely popular, of 'Evolution' with 'Darwinism.' Evolution must clearly be retained to denote the entire drama of cosmic change; Darwinism, therefore, must as clearly be restricted to one particular interpretation of the mechanism and plot of this cosmic drama, of many which have been thrown out by reflective spectators. Darwin expressed the mode of the evolutionary process in a classic phrase, the title of his great work—*The Origin of Species by means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life*. That explanation is not only in itself peculiarly shrewd and well reasoned, luminous and widely applicable, but has been of the very greatest importance in awakening biologists and students of all other sciences, and thus ultimately the intelligent public, to the facts of the case—to the consciousness of this evolutionary drama. On the promulgation of this new hypothesis as to the mode of occurrence of evolutionary changes in the organic world, the whole discussion as to the occurrence of evolutionary change at all speedily came to centre round it; although in view of the powerful arguments for the occurrence of evolution which had been independently adduced by Spencer and others, it may be admitted this was not quite logical. The fact, however, remains. Moreover to the new standpoint afforded by the clear acceptance of both ideas—evolution and this through natural selection—and to the energetic application of these, first by Darwin himself, but soon by a multitude of zealous workers, we owe a progress which it would as yet be premature to estimate, but which has pervaded the whole field of biology, and even the fields of all the higher sciences, mental and social, which so largely utilise biological methods and generalisations. Whatever may be the subsequent development of our evolutionary conceptions, the epoch-making importance of the Darwinian theory will be unaltered. Hence the expediency of the present comparatively full exposition of its main positions and of their bearings, apart from the larger and more general argument under EVOLUTION.

To the statement of Darwin's theory, therefore, we may at once proceed, postulating no more than that general acquaintance with the aims and results of biology which is now becoming so commonly current, or which may readily be gained by help of the articles BIOLOGY and BOTANY. Nor need any statement of the general doctrine of evolution, or of evolutionary theories before Darwin, here detain us, since these find more fitting place in the general article EVOLUTION.

The failure of pre-Darwinian theories to gain any very general acceptance among naturalists was no doubt largely attributable to established prejudice, backed as this was by the predominant authority of Cuvier. This was by no means the whole explanation. For while those theories rendered it extremely probable that modification had occurred, they all fell short, as Darwin pointed out, in one most important particular. They failed to show how the modification of one species from another could take place, 'so as to acquire that perfection of structure and co-adaptation which justly excites our admiration;' since the hypotheses of the potency of external conditions, of habit, of the volition of the organism itself, and so on, alike successively broke down.

Darwin was especially struck by the distributional phenomena he witnessed during his 'Naturalist's Voyage,' and thereafter devoted himself primarily to the problem of the origin of

species, specially concentrating himself upon what seemed to him the weakest point of the preceding theories, the explanation of adaptations. Commencing in 1837, 'after five years' work, I allowed myself to speculate on the subject, and drew up some short notes; these I enlarged in 1844 into a sketch of the conclusions which then seemed to be probable; from that period to the present day I have steadily pursued the same object.' This was written as late as 1859, and even then because he had received a paper from Mr A. R. Wallace (at that time exploring the Malay Archipelago), in which views identical with his own were expressed, and thus was compelled to proceed to the publication of his results. He did so first in a brief outline read, by advice of Lyell and Hooker, simultaneously with Wallace's paper (see *Jour. Linn. Soc.*, 1858); and in the following year in that fuller abstract, as at first he merely regarded it, which soon became so famous—the *Origin of Species*. Its substance may with advantage be briefly summarised, so far as further compression of such 'intellectual pemmican' is possible. For details and explanations the reader must consult the work itself (7th ed. 1880).

Outline of 'Origin of Species.'—In order to gain insight, then, into the means of modification, Darwin commences with a study of the variation of plants and animals under domestication (later expanded into a separate work; 2d ed. 1876).

Variation and Heredity.—While all plants and animals exhibit some degree of variation, this is greatest among domesticated species, owing to their new and less uniform conditions of life. These may act directly on the whole organisation, or on separate parts, and the variation, though rarely, is sometimes definite, as when size increases with quantity of food, or colour changes with its quality; or the conditions may act indirectly by influencing the reproductive system, which is peculiarly sensitive. Changed habits produce an inherited effect—e.g. the leg-bones of the common duck weigh proportionally more, and its wing-bones less, than in the wild variety, because it flies less and walks more. So, too, tame mammals acquire drooping ears, since these are rarely pricked in alarm. One variation is usually correlated with others, thus long-beaked pigeons have small feet, and conversely. All variations tend to be inherited. The popular belief that domestic races simply revert to the aboriginal stock is unsupported by facts.

Save that domestic varieties are less uniform than wild species, often differ more widely in some single part, and are fertile when crossed, there is no well-marked distinction between these and so-called true species. If, therefore, such varieties as the different breeds of the dog can be shown to be descended from a single wild species, there necessarily arises great doubt as to the immutability of closely allied natural species, such as the foxes. While, however, the many breeds of dog appear to have arisen from several wild species, and those of cattle also from two or three, our fowls, ducks, rabbits, &c., all certainly arise from a single ancestral species. The case of pigeons is of peculiar importance, since pouter, carrier, fantail, and tumbler differ so thoroughly, externally and internally, that any ornithologist would be compelled to assign to them not merely specific but generic distinctness, if he had discovered them in the wild state. There is at least as much difficulty in believing that such breeds can have proceeded from a common ancestor, as there is in the case of any group of birds in nature; and every breeder of these has been firmly convinced of their descent from distinct species. Yet all these breeds are proved to come from the common rock-dove (*Columba livia*; see PIGEON),

and thus those who admit the unity of domestic races should be cautious in deriding the unity of wild ones.

Domestic races all exhibit adaptations to man's use or fancy, rather than to their own good. The key to this is man's power of selection: nature gives successive variations, man accumulates these, so making for himself useful breeds, and often (e.g. in sheep, cattle, roses, dahlias) profoundly modifies their character even in a single human lifetime; so that in all characters to which he attends, they may differ more than the distinct species of the same genera. Again, that unconscious selection which results from every one trying to possess and breed the best animals is yet more important than conscious selection. Two flocks of Leicester sheep, kept equally pure, appeared of quite different varieties after fifty years. Such slowly accumulated change explains why we know so little of the origin of domestic races; and its absence in regions inhabited by uncivilised man explains why these yield no plants worth immediate culture. Human selection is facilitated (1) by the keeping of large numbers, since variations will be more frequent, and (2) by preventing free-intercrossing; some species vary, however, more than others.

Variation under Nature.—All similar organisms in nature present individual differences, more considerable than is usually supposed. No two blades of grass are alike, and far more marked differences often occur, several castes or varieties sometimes existing in the same sex. Between these castes, and much more frequently between forms which systematic botanists and zoologists rank as true species, perfectly intermediate forms may occur. No agreement about the definition of species (the amount of difference necessary to give any two forms specific rank) has ever been come to; thus, in the British flora alone, there are nearly two hundred disputed forms, and individual opinion is in these cases the only criterion. As long as a genus is imperfectly known, and its species founded upon few specimens, they appear clearly limited. But with fuller knowledge, intermediate forms come in, and doubts as to specific limits augment. The terms species and variety are thus arbitrarily given to sets of individuals more or less closely resembling each other. See VARIETY, SPECIES, GENUS.

Individual differences are thus of the highest importance, as the first steps towards the slightest varieties worth recording, these in turn towards more distinct and permanent varieties, these varieties again towards sub-species, and in the next stage to species; though extinction may often arrest the process.

The species which present most varieties are those which have the greatest geographical range, or the widest diffusion in their own territory, or which possess the greatest number of individuals. In the larger genera of each country the species vary more frequently than in the smaller genera; and in many respects the species of large genera present a strong analogy with varieties, which analogy is alone intelligible on the view that they once existed as mere varieties themselves.

Struggle for Existence.—All organic beings tend to increase with extreme rapidity, so that if they were not kept down, the earth would soon be covered by the progeny of a single pair. This is evidenced not merely by calculation, but by actual observation of the extraordinary rapidity with which plants and animals have spread, when introduced into new and favourable circumstances (e.g. thistles and rabbits into Australia).

Since organisms then are reproducing themselves so rapidly, and since all their offspring cannot escape their enemies, get food, and live, much less

leave progeny in turn—since, in other words, the doctrine of Malthus applies to animals and plants with manifold force (for these can have no artificial increase of food, and no prudential restraints on reproduction)—there must in every case be a *struggle for existence*, either of one individual with another of the same species, or with the individuals of distinct species, or with the physical conditions of life; often, indeed, with all these at once, and that more or less intensely throughout the whole of life.

The checks which prevent increase are most obscure, and vary in each case. In all cases the amount of food, of course, gives the extreme limit. The youngest organisms generally suffer most; seedlings, for instance, are destroyed in vast numbers. Thus, even in a patch of ground purposely dug and cleared, where no choking from other plants could take place, 295 out of 357 seedling-weeds were destroyed, chiefly by slugs and insects. So, too, the stock of game on an estate depends chiefly upon the destruction of vermin. Climate, however, is highly important, and periodic seasons of extreme cold and drought seem the most effective of all checks—a severe winter sometimes destroying four-fifths or more of the birds of a locality. Epidemics, too, may occur, especially where numbers have inordinately increased. On the other hand, a large number of individuals of the same species is essential for its continued preservation.

The complex relations of all animals and plants to each other require illustration. The planting of part of a heath with Scotch fir leads to a profound alteration of its flora and fauna, while the growth of these firs again is wholly dependent upon the exclusion of cattle. Many flowers depend for fertilisation on the visit of a special insect—e.g. red clover on humble-bees. But bees are destroyed by field-mice, and consequently protected by cats; hence, not only no bees, no clover, but also the more cats, the more clover! The struggle for life is most severe between individuals and varieties of the same species, and between the species of the same genus, since these tend to fill the same place in the economy of nature; hence we see the brown rat supplanting the black, and the hive-bee supplanting its Australian congener. The structure of every being is related to that of the others with which it competes, or from which it seeks to escape, or on which it preys; as is alike evident in the structure of the tiger and of the parasite which clings to his hair. So, too, the albumen of a seed is chiefly useful in favouring the young plant's struggle for light and air against the adult plants around.

Natural Selection.—But how will the struggle for existence act with regard to variation? Can the principle of selection, so potent in the hands of man, apply under nature? Most efficiently so. Let us bear in mind (1) the constant occurrence of variation; (2) the infinite complexity of the relations in which organisms stand to each other, and to the physical conditions of life; and consequently (3) what infinitely varied diversities of structure might be useful to each being under changing conditions of life. Can it then be thought improbable, seeing that variations useful to man have undoubtedly occurred, that other variations useful in some way to each combatant in the great and complex battle of life should also occur in the course of many generations? And if such do occur, can we doubt (remembering that many more individuals are born than can possibly survive) that individuals having some advantage, however slight, have the best chance of surviving and of reproducing their kind, while injurious variations are destroyed? This preservation of favourable variations, and the destruction of injurious ones,

is termed Natural Selection, or less figuratively, the Survival of the Fittest.

Taking the case of a country undergoing a change of climate, the proportional numbers of its denizens would change, some species probably becoming extinct—and these changes* would in many ways affect the survivors. A further disturbance would come from the immigration of new forms; or if that were prevented, we should have places in the economy of nature which might be better filled up. Any slight favourable modification of the old species would tend to be preserved, and we have seen that changed conditions increase variability.

Nor are such changes necessary in order to leave places for natural selection to fill. No country can be named where the native inhabitants are perfectly adapted to their conditions and competitors, for as some foreigners have taken firm possession in every country, we may safely conclude that the natives might have been modified with advantage to resist them.

And when human selection has produced such great results, why may not natural? Human selection acts only for man's own good, on mere external and visible characters, and irregularly throughout a short period; natural selection acts for the good of the being itself, on the whole machinery of its life, and incessantly on the species, throughout almost infinite time. (It is important here to remember that the objection to this agency on the ground of its presumed insignificance, is identical with that so long but unsuccessfully employed against Lyell's explanation of the origin of the physical features of the globe by summing up the existing natural changes.)

Natural selection thus leads to the improvement of each creature in relation to its organic and inorganic conditions of life, and consequently in most cases to what must be regarded as an advance in organisation. Nevertheless, low and simple forms will long endure, if well fitted for their simple conditions.

Natural selection may modify the egg, seed, or young, as easily as the adult, and these modifications may effect through correlation the structure of the latter, and conversely.

Besides Natural, we have to consider Sexual Selection—i.e. not merely do individuals struggle for existence, but the males struggle for the females, and the most vigorous thus tend to leave most progeny. Special weapons, offensive and defensive, like the cock's spur, the stag's horns, or the lion's mane, are used in this struggle, and the most useful variations are those which are transmitted. Again, just as man can in a short time give beauty to his domestic birds, so there is no good reason to doubt that female birds in thousands of generations, by selecting, as they are observed to do, the most melodious or beautiful males, might produce a marked effect, and many sexual differences are thus explained.

The theory of natural selection may be applied in special cases—e.g. (1) to explain the evolution of swift greyhound-like varieties of wolves; (2) to explain the origin and the excretion of nectar in flowers, its use to insects, the action of insects in transferring pollen from flower to flower, with its advantage in intercrossing; and the resultant modification and adaptation of flower and insect to each other by the preservation of advantageous variations.

The circumstances favourable to the production of new forms through natural selection are also reviewed. These are chiefly, great variability; large numbers of individuals; the complex effects of intercrossing; isolation in small areas, yet also extension over continental ones, especially if these

vary in altitude; and considerable lapse of time. Rare species are shown to be in process of extinction. The *divergence of character* in domestic breeds, largely due to the fact that 'fanciers do not, and will not, admire a medium standard, but like extremes,' applies throughout nature, from the circumstance that the more diversified the descendants from any one species become in structure, constitution, and habits, by so much will they be better enabled to seize on many and widely diversified places in nature, and so to increase in numbers. Thus, taking a carnivorous animal which has reached the maximum numbers its territory will support, it is evident that it can succeed in increasing only by its varying descendants seizing places hitherto occupied by other animals. This must hold equally of all species, and is separately demonstrated for plants. The greatest amount of life can be supported by help of proportionally great diversification of structure; hence, in small areas where competition is severe, the inhabitants are extremely varied.

The probable effects of the action of Natural Selection, through divergence of character and extinction, on the descendants of a common ancestor are then discussed in detail by Mr Darwin with an illustrative diagram. This takes the form of a genealogical tree—'the great tree of life, which fills with its dead and broken branches the crust of the earth, and covers the surface with its ever-branching and beautiful ramifications.'

Laws of Variation (see VARIATION).—Of the cause of most variations we are still ignorant, but the same laws appear to have acted in producing the lesser differences between varieties of the same species and the greater differences between species of the same genus. Changed conditions sometimes induce definite and permanent effects: habit, use, and disuse are potent in their effects. Specific characters are more variable than generic, and varietal than either. Rudimentary organs and secondary sexual characters are highly variable. Species closely related of similar constitution and similarly influenced, present analogous variations, and frequently exhibit characters which can only be explained as reversions to those of their ancient progenitors—e.g. zebra-like stripes on horses, or wood-pigeon's markings on fantails, tumblers, &c.

Difficulties and Objections.—In four chapters all the miscellaneous objections raised against the theory between 1859 and the appearance of the latest edition are successively stated, weighed, discussed, and met, as well as the much more serious difficulties pointed out by Darwin himself. These latter are, (1) the definiteness of species and the rarity of transitional forms; (2) the enormous degree of modification in habits and structure assumed by the theory, and the seeming improbability that Natural Selection should produce on the one hand an organ of such trifling importance as the tail of a giraffe, and on the other, an organ so wonderful as the eye; (3) the acquirement and modification through Natural Selection of such marvellous instincts as those of the bee; (4) the sterility of crossed species, and the fertility of crossed varieties. For these discussions, however, the reader must consult the work itself.

Imperfection of the Geological Record.—On the assumption of the extermination of an enormous number of intermediate varieties, which were the links between existing and remote ancestral forms—why, then, is not every geological formation charged with such links? Why does not every collection of fossils afford plain evidence of the gradation and mutation of the forms of life? Geology, assuredly, does not reveal any such finely graduated organic chain, and this is one of the most obvious and plausible objections to the

theory. The explanation offered is the extreme—the almost incredible—imperfection of the geological record. Only a small portion of the globe has been geologically explored with care; only certain classes of beings have been fossilised; and the number, both of specimens and species yet discovered, is absolutely as nothing compared with the number which must have passed away during even a single formation. The Malay Archipelago equals in area the formations best known to us; its present condition represents that of Europe while Europe's strata were being deposited; its fauna and flora are among the richest on the globe, yet, even if all the species were to be collected which ever lived there, how imperfectly would they represent the natural history of the world! Only few species are preserved at all, and most of these in an imperfect manner; moreover, subsidence being almost necessary for the accumulation of rich deposits, great intervals of time must have elapsed between successive formations, so that during periods of elevation, when variation would be most frequent, the record is least perfect. Moreover, geological formations have not been continuously deposited; the duration of specific forms probably exceeds that of each formation; migrations have largely taken place; widely ranging species are most variable, and oftenest give rise to new species; varieties have been at first local; and finally, it is probable that periods of modification are short as compared with periods of permanence. Hence we cannot find innumerable varieties, and any linking variety between two forms is, of course, ranked as a distinct species, for the whole chain cannot be permanently restored. Thus the geological record is a history of the world indeed, but one imperfectly kept, and written in a changing dialect; of this history we possess the last volume only, relating to two or three countries. Even of this volume only here and there has a short chapter been preserved, and of each page only here and there a few lines.

Geological Succession of Organic Beings (Distribution in Time).—The preceding difficulties excepted, the facts of palaeontology agree admirably with the theory. New species come in slowly and successively; they change in different rates and degrees; old forms pass through rarity to extinction, and never reappear; dominant forms spread and vary, their descendants displacing the inferior groups, so that after long intervals of time the productions of the world appear to have changed simultaneously. The most ancient forms differ most widely from those now living, yet frequently present characters intermediate between groups now widely divergent, and they resemble to a remarkable extent the embryos of the more recent and more highly specialised animals belonging to the same classes. These laws, and, above all, the important law of the succession of the same types within the same areas during the later geological periods, and most notably between the Tertiary period and the present time (e.g. fossil and recent marsupials in Australia, and edentates in South America), cease to be mysterious, and become at once thoroughly intelligible on the principle of inheritance, and on that alone.

[Since the publication of the *Origin of Species* in 1859, palaeontological research has been constantly furnishing the most triumphant verification of these views. The imperfection of the geological record was so far from overestimated that Huxley (*Science and Culture*, 1880), in comparing our present knowledge of the mammalian Tertiary fauna with that of 1859, states that the results of the investigations of Gaudry, Marsh, and Filhol are 'as if zoologists were to become acquainted with a country hitherto unknown, as rich in novel forms of life as Brazil or South Africa once were to

Europeans.' Gaudry has found the intermediate stages by which civets passed into hyænas; Filhol has disinterred still more remote ancestral carnivores; while Marsh has obtained a complete series of forms intermediate between that, in some respects, most anomalous of mammals, the horse, and the simplest five-toed ungulates (see MAMMALIA). Again, Darwin's belief that the distinctness of birds from all other vertebrates was to be accounted for by the extinction of a long line of progenitors connecting them with reptiles, was in 1859 a mere assumption; but in 1862 the long-tailed and intensely reptilian bird *Archæopteryx* (q.v.) was discovered, while in 1875 the researches of Marsh brought to light certain cretaceous birds, one (*Hesperornis*) with teeth set in a groove, the other (*Icthyornis*) with teeth in sockets, and with bi-concave vertebrae. Besides these reptilian birds, bird-like reptiles have similarly been forthcoming, and the hypothesis of Darwin is thus admirably verified. Considerable light, too, has been thrown on the pedigree of crocodiles; ammonites, trilobites, and other invertebrates have been arranged in series, while important collateral evidence is also furnished by 'persistent types' such as *Ceratodus*, *Beryx*, *Nautilus*, *Lingula*, &c., which have survived—we must assume by ordinary generation—almost completely unchanged since remote geological periods. On such grounds, therefore, Huxley asserts (*op. cit.*) that 'on the evidence of palaeontology, the evolution of many existing forms of animal life from their predecessors is no longer an hypothesis, but an historical fact; it is only the nature of the physiological factors which is still open to discussion.'

Geographical Distribution.—Neither the similarity nor the dissimilarity of the inhabitants of various regions, whether of land or sea, can be accounted for by identity or differences of climate, or other physical conditions, but both are related in the most striking degree to the absence or presence of barriers to migration between those regions. Within the same area there exists the most marked affinity among the species, though these differ from place to place. Species appear to have arisen in separate definite centres, the few apparent exceptions being accounted for by migration and dispersal, followed by climatic and geographical changes. But for a summary of our knowledge of the existing mode of distribution of organic life, and of the way in which that distribution has been effected, as well as of the very important bearing of these facts upon the theory of evolution, which they may be said, indeed, more than any other class of facts, to have suggested, see the article GEOGRAPHICAL DISTRIBUTION.

Morphological Arguments.—The physiological and distributional lines of argument being summarised, those furnished by morphology, although not less numerous and highly important, can only be very briefly outlined. These are mainly four, and are derived from (a) Classification, (b) Homologies, (c) Embryology, (d) Rudimentary Organs.

(a) *Classification.*—Naturalists arrange the species, genera, and families in each class, on what is called the Natural System. But what is meant by this system? Is it, after all, merely an artificial scheme for enunciating general propositions, and of placing together the forms most like each other? or does it, as many believe, reveal the plan of creation? The grand fact of classification is, that organic beings, throughout all time, are arranged in groups subordinated under other groups—individuals under varieties, and these again under species; species under genera; genera under sub-families, families, and orders; and all under a few grand classes. The nature of all these relationships—the rules followed and the difficulties met

by naturalists in their classifications—the high value set upon constant and prevalent structures, whether these be of great or little use, or, as with rudimentary organs, of none at all—the wide opposition in value between such misleading resemblances of adaptation, as, for instance, the fish-like form of whales, and such characters of true affinity as are afforded by the structure of their circulatory or respiratory system—all these receive a simple and natural explanation on the view of the common descent of allied forms with modification through variation and natural selection; while it is to be noted that no other explanation has ever even been attempted. The element of descent, too, is already used in linking all the sexes, ages, forms, and varieties of the same species, widely though these (e.g. *Cirripedes*) may differ from each other in structure: and we have only to extend it to understand the meaning and origin of the Natural System.

(b) *Homology*.—The members of the same class, independently of their habits of life, resemble each other in their general plan of organisation. Thus, the hand of man, the digging-paw of the mole, the leg of the horse, the paddle of the porpoise, and the wing of the bat, are all constructed on the same pattern, bone corresponding to bone. Similarly with the hind-limb. Again, the mouths of insects are of innumerable varieties of form and use—witness the long spiral trunk of a moth, and the great jaws of a beetle—yet these are formed by modifications of an upper lip, mandibles, and two pairs of maxillæ. And so it is with the limbs of crustaceans, or the flowers of plants; in fact, with the organs of every class of beings.

This *conformity to type* is 'powerfully suggestive of true relationship, of inheritance from a common ancestor'; it admits, in short, as no one indeed denies, of a simple explanation in terms of the evolutionary theory, and thus strengthens that theory not a little. Attempts have been made to explain this unity of plan in two other ways—first, by assuming it due to utility, which is negatived by the facts, since organs of identical use (e.g. the wings of a bird and those of a butterfly) very frequently do not conform to the same type at all; secondly, by attributing it to a unity of design, which, however, (a) instead of being always maintained, as it should be, on the theory, is not unfrequently quite lost in highly specialised forms; and which, even if it always existed, (b) would directly suggest the unity of descent, the design thus serving only to mislead the anatomist.

Serial Homology, too, has to be accounted for—that unity of type which is found on comparing the different parts and organs in the same individual, so that the wonderfully complex and varied jaws and legs of a lobster, or the widely different leaves, sepals, petals, stamens, and pistils of a flower, are all found to be modifications of a simple limb, and a simple leaf-organ respectively. Not only are such metamorphoses apparent on comparison, but they can be actually observed to occur during the development of each individual; is then the term *metamorphosis* to have a mere metaphorical meaning when applied to the species, or has it not actually arisen in past time, through the natural selection and transmission of advantageous variations?

(c) *Development*.—It has been already indicated that the serially homologous parts in the same individual are alike during an early embryonic period, as also are the homologous organs in animals which, like bat, horse, and porpoise, may be widely differentiated in adult life. So closely, too, do the embryos of the most distinct species belonging to the same class resemble each other, that even Von Baer was unable to distinguish whether two un-

labelled specimens were lizards, birds, or mammals. This law of embryonic resemblance holds very widely—e.g. with young crustaceans. The embryo often retains within the egg or womb structures which are of no service to it, either at that or at a later period of life, like the transitory gill-arches of birds or mammals; while, on the other hand, larvæ (e.g. of insects), which have to provide for their own wants, undergo complete secondary adaptation to the surrounding conditions. The process of development goes from the general to the special; thus there is generally an advance in organisation. In peculiar conditions, however, degeneration may occur. All these facts are readily explained on the principle of successive slight variations not necessarily or generally supervening very early in life, and inherited at a corresponding period; hence it is in the highest degree probable that most embryonic stages show us more or less completely the progenitor of the group in its adult state; and embryology thus rises greatly in interest. See EMBRYOLOGY.

(d) *Rudimentary Organs*.—Rudimentary, atrophied, and abortive organs, bearing the plain stamp of inutility, are so extremely common that it is impossible to name a higher animal in which none occurs. The mamma of male mammals, the hind-legs of boas, the wings of many birds, or the teeth of foetal whales, and the upper incisors of unborn calves, are familiar instances. Such organs are intelligible on the evolutionary theory, and on that theory alone.

Recapitulation and Conclusion.—After tersely summing up the preceding mass of evidence, Darwin concludes by pointing out (a) that the theory of evolution by natural selection is no more inimical to religion than is that of gravitation, to which the same objection was strongly raised; (b) its revolutionary influence on the study of all departments of natural history; (c) on Psychology (q.v.); (d) on the origin of man and his history (see MAN); (e) on our theories of future progress.

Envoy.—It is interesting to contemplate a tangled bank clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent on each other in so complex a manner, have all been produced by laws acting around us. These laws, taken in the largest sense, being Growth with Reproduction; and Inheritance, which is almost implied by reproduction; Variability from the indirect and direct action of the conditions of life, and from use and disuse; a Ratio of Increase so high as to lead to a Struggle for Life, and as a consequence to Natural Selection, entailing Divergence of Character and the Extinction of less improved forms. Thus, from the war of nature, from famine and death, the most exalted object which we are capable of conceiving, namely, the production of the higher animals, directly follows. There is grandeur in this view of life, with its several powers, having been originally breathed by the Creator into a few forms, or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being, evolved.

The stormy reception of the *Origin of Species*, the controversies to which it gave rise, its rapid and widespread acceptance, helped as it was by the independent support, yet generous self-abnegation, of Mr Wallace, and the powerful advocacy of Huxley, Hooker, Asa Gray, and others, are all recorded in Darwin's Life. Of the proposed expansion of the *Origin*, only the first chapter actually

appeared, as *Variation of Animals and Plants under Domestication* (see VARIATION); but in *Fertilisation of Orchids, Forms of Flowers, Insectivorous Plants, Climbing Plants, Movement in Plants*, we have a series which not only greatly developed Darwin's favourite study of adaptations, and with it enormously strengthened his general theory, but gave to the arid field of botany the interest and freshness of a new intellectual spring (see BOTANY). Again, the very difficulties which he felt to be presented to his theory by the complex phenomena of bee and ant society led him onwards, till he reached the problems of mind and language: the obvious and burning question of the origin of man had also to be faced, and thus we had the *Descent of Man* and the *Expression of the Emotions*.

Before conclusion, justice demands, if not discussion, at least mention of some of the more important criticisms which have been urged against Darwin's theory. That which Darwin himself seems to have felt as most serious was made by Fleeming Jenkin, who laid stress on the tendency to swamping any individual variation, however advantageous, through intercrossing. Mr Mivart's *Genesis of Species* next engaged him most; but Darwin's replies to these and other criticisms up to 1872 will be found in the final edition of the *Origin of Species*. In his essay in Darwin's Life, Huxley says, 'I venture to affirm that so far as all my knowledge goes, all the ingenuity and all the learning of hostile critics have not enabled them to adduce a single fact of which it can be said this is irreconcilable with the Darwinian theory;' while Mr Ray Lankester still more recently assures us that 'since its first publication in 1859 the history of Darwin's theory has been one of continuous and decisive conquest, so that at the present day it is universally accepted as the central, all-embracing doctrine of zoological and botanical science.'

As a matter of fact, however, this 'universal acceptance' is not without its universally distributed exceptions. Some of Darwin's contemporaries have withheld their adhesion—e.g. Virchow in Germany, Owen and Cleland in Britain, and the older French naturalists; nor can the critical and controversial writings of Mivart, the Duke of Argyll, Samuel Butler, and others, be thus wholly ignored. Constructive criticism is also busy. On one hand certainly we have the ultra-Darwinian speculations of Weismann, warmly accepted by Lankester and others; but on the other, attempts are again being made, and with increasing frequency, to restate the theory of evolution more or less completely in non-Darwinian terms. Thus, following up the doubt which occasionally troubled Mr Darwin's recent years, that he had assigned too little importance to the modifying factors of use and disuse, of environment, &c., we have Mr Spencer re-entering the field; in America an active Neo-Lamarckian school has also arisen, which lacks neither knowledge nor thoughtfulness; in Germany we owe new constructive efforts to Nägeli and Semper, and more recently to Eimer; while in Britain, complementary hypotheses have been propounded by Romanes, Sutton, Gulick, Geddes, &c. But such proposed positive contributions to the evolutionary theory fall rather to be treated under EVOLUTION.

See BIOLOGY, BOTANY, EVOLUTION, ENVIRONMENT, HEREDITY, GEOGRAPHICAL DISTRIBUTION, ZOOLOGY, and other articles. Besides the works of Darwin himself, and those of Alfred Russell Wallace (from *Natural Selection* in 1870 to *Darwinism* in 1889), with the special treatises referred to under the above-mentioned and minor articles (e.g. FERTILISATION), see F. Darwin's *Life of Charles Darwin*; also minor Lives by Grant Allen and Bettany. Of other expository literature may be

mentioned Haeckel's *Generelle Morphologie und Natural History of Creation*; Huxley's *Lesser Sermons, American Addresses, Science and Culture, Anatomy of Invertebrated Animals*; also his essay *On the Reception of the Origin of Species* in Darwin's Life, vol. ii.; *Obituary Notice of Charles Darwin* in *Proc. Roy. Soc.* (Lond. 1888); and *Struggle for Existence, a Programme* (*Nineteenth Century*, 1888). Weismann's *Studies in the Theory of Descent* (1880-82), and for more recent developments his subsequent papers (see HEREDITY, REPRODUCTION), must also be noted. Romanes' *Scientific Evidences of Organic Evolution*, Lankester's *Degeneration* (both *Nature* series), Schmidt's *Doctrine of Descent and Darwinism*, Fiske's *Darwinism and other Essays*, are examples in English of an abundant and more popular literature, in which the writings of Mr Grant Allen and Dr A. Wilson are also specially known, and which is likewise abundant in Germany, France, and Italy.

Of controversial writings may be cited Mivart's *Genesis of Species, Lessons from Nature*, &c.; the Duke of Argyll's *Unity of Nature*, as well as the review articles of both writers. See also Butler's *Evolution, Old and New*, and *Luck or Cunning*. For the literature of the more constructive attempts referred to, see EVOLUTION. For general bibliography Bettany's *Life of Darwin* is most accessible; while complete help will be obtained from Seidlitz, *Die Darw. Theorie* (Leip. 1875), and from the Naples *Jahresbericht f. Zoologie*; preferably, however, since 1886 from the *Zoological Record*.

Darwin Sound and **MOUNT DARWIN** are on the SW. side of King Charles's South Land, Tierra del Fuego. The mountain rises 6800 feet.

Dasent, SIR GEORGE WEBBE, was born in 1820 at St Vincent in the West Indies, of which island his father was attorney-general. He was educated at Westminster School and King's College, London; graduated B.A. at Magdalen College, Oxford, in 1840; and was called to the bar at the Middle Temple in 1852, in which year also he received his degree of D.C.L. He acted some years as an assistant-editor in the *Times* office, and married a sister of its editor, Mr Delane. An accomplished linguist, he had often acted as examiner in English and modern languages for civil service appointments, when he was appointed a Civil Service Commissioner in 1870, and knighted 'for public services' in 1876. Already in 1842 he published a translation of *The Prose or Younger Edda*; which was followed by an essay, 'The Norsemen,' in the *Oxford Essays* (1858); *Popular Tales from the Norse, with an Introductory Essay on the Origin and Diffusion of Popular Tales* (1859), and *Tales from the Fjeld* (1874), both from the Norwegian of Ashbjørnsen; translations from the Icelandic of the *Saga of Burnt Njal* (1861), and the *Story of Gisl, the Outlaw* (1866); and an Introduction and Life of Cleasby, prefixed to Vigfusson's completion of Cleasby's unfinished *Icelandic-English Dictionary* (1874). Sir George Dasent has also written several fair novels. His famous introduction to Ashbjørnsen's *Popular Tales* was a solid contribution to folklore, being an admirable exposition of the Aryan theory of story-transmission as advocated by Grimm and Max Müller.

Dash, COUNTESS, the name under which Gabrielle Anna Cisterne de Courtiras, Vicomtesse de Saint-Mars, published a series of novels, many of which were readable, if of but slender literary merit. She was born at Poitiers, August 2, 1804, of a noble family, married early, and took to literature for a living after the loss of her property, writing sometimes as many as five or six novels a year. She died 11th September 1872. Her stories deal almost exclusively with the aristocratic world and its more or less illegitimate liaisons. They have a certain brightness and vigour, but lack reality, and are peopled by a crowd of stilted puppets rather than living men and women. Of her numberless books may only be mentioned

Les Amours de Bussy-Rabutin (1850), *La Pomme d'Ève* (1853), *Le Galantries de la Cour de Louis XV.* (1861), *Comment Tombent les Femmes* (1867), and *Les Aventures d'une Jeune Mariée* (1870).

Dashkoff, PRINCESS EKATERINA ROMANOVNA, daughter of Count Voronzoff, was born 23th March 1743, at St Petersburg, and from her earliest youth received a careful training. She married Prince Dashkoff when only fifteen years old, but was left a widow three years after. She was an intimate friend of the Empress Catharine II., and one of the heads of the conspiracy formed against Peter III., the success of which secured the throne to Catharine. Soon afterwards quarrelling with Catharine, she obtained permission to travel, and visited Germany, England, France, and Italy, making the acquaintance of many eminent men (among others, Garrick, Dr Blair, and Dr Robertson). The empress and she were reconciled to each other, and the princess was appointed Director of the Academy of Arts and Sciences; and in 1783, President of the Russian Academy, established at her own suggestion in imitation of the French Académie. On the death of Catharine in 1796, she was deprived of her offices, and ordered by Paul III. to retire to her estates at Novgorod. She died 16th January 1810. Besides writing several comedies and occasional papers, the Princess Dashkoff was mainly instrumental in inducing the Russian Academy to draw up a dictionary of the Russian language, and herself executed part of the work. Her very interesting autobiography was published in English by her friend Mrs Brailford (2 vols. 1840).

Dasyure (*Dasyurus*), a genus of carnivorous marsupials, including forms which in the Australian and Tasmanian fauna take the place filled in other regions by carnivores. The large sharp canines, the sharp-pointed cusps on the back teeth, and the clawed toes are among the adaptive carnivorous features, and there are others of a more technical nature. The dasyures are nocturnal and savage animals, and as one would expect, peculiarly untamable. One of the most pronounced is the Tasmanian Devil (*D. ursinus*), a savage animal, about the size of a badger, with a disproportionately large and broad head, and massive crowded teeth. The body is plump; the fur is coarse and brownish-black, with a white band on the chest, and another at the end of the back; the tail is

Tasmanian Devil (*Dasyurus ursinus*).

thick, and about half as long as the body. In Tasmania these 'devils' used to commit great havoc among poultry and even sheep, but are being driven into more and more remote haunts. The Spotted Dasyure (*D. maculatus*), also Tasmanian, is a much smaller animal, about the size of a cat. Another 'wild cat' of the same country and Victoria is Mauge's Dasyure (*D. maugei* or *viverrinus*). Other species occur in Australia and New Guinea. Nearly allied to the dasyures are two genera,

Thylacinus and *Phascogale*. The former, the Thylacine (q.v.) or Tasmanian wolf, is the largest carnivorous marsupial; the latter is insectivorous. See MARSUPIAL.

Date. See CHRONOLOGY.

Date Palm (*Phoenix*), a genus of palms, the most important species of which is the Common Date Palm, the *Palm Tree* of Scripture (*P. dactylifera*), a native of the northern half of Africa, the southwest of Asia, and some parts of India, and of which the cultivation is no less wide, and still extending.

Date Palm :

a, bunch of dates dependent from their spathe; b, portion of leaf.

Some parts of China produce large crops. The stem, which is straight and simple, reaches a height of 30 to 60 feet, and bears a head of 40 to 80 glaucous pinnated leaves, of 8 to 10 feet long, and a number of branching spadices, each of which on the female tree bears 180 to 200 fruits (dates, *dactyli*). A bunch of dates weighs 20 or 25 lb., so that an average year's crop may be reckoned at 300 to 600 lb. per tree, and the yield per acre at about twelve times that of corn. From the earliest times fertilisation has been artificially aided by cutting off the male inflorescences just before the stamens ripen, and suspending them among those of the female tree; so avoiding the risks and losses of ordinary wind-fertilisation. In a palm grove there may be but one male stem to forty or fifty fruit-bearing ones. The Arabs seldom raise palms from seed; to make sure of the sex they take suckers from female trees known to bear good fruit. The tree begins to bear about the eighth year, reaches maturity at about thirty years, and does not decline until about the age of one hundred. This is one of the most important and useful of all the palms. In Egypt, and generally in North Africa, Persia, and Arabia, dates form the principal food, and date palms the principal wealth of the people. The fleshy part of the fruit contains 58 per cent. of sugar, accompanied by pectin, gum, &c. The fruit is eaten either fresh or dried, and in the latter state becomes an article of commerce. Cakes of dates pounded and kneaded together, and so solid as to be cut with a hatchet, are the store of food provided for African caravans on their journey through the Sahara. A sweet juice (date-honey) can be expressed from the fruits, from which a kind of wine is obtained by fermentation; also a sort of vinegar; an ardent spirit is of course also distilled from the fermented juice. Palm-wine is also made from the sap after the terminal bud is removed. The bud is eaten as palm-cabbage, similarly also the undeveloped panicles of flowers. The date

'stones' or seeds are roasted in North Africa as a substitute for coffee, and have also been introduced into Britain for the same purpose. They are also ground and pressed for oil, and the residue used for feeding cattle. From leaf-stalks of the common date palm, all kinds of basket and wicker work are also made, and walking-sticks, fans, &c. The leaves themselves are made into bags, mats, &c.; the fibres of the web-like integuments at the base of their stalks into cordage. The wood is used for building, fences, &c.—The Toddy Palm of the north of India, or Wild Date Palm (*P. sylvestris*), so nearly resembles this species, that it is doubtful if it is distinct. In some places, the trees present a curiously distorted and zigzag appearance, from the practice of yearly tapping the alternate sides for the sap or *toddy*. This forms a grateful and wholesome beverage; readily also fermenting into palm-wine, and by distillation yielding *Arrack* (q.v.); whilst if boiled down it yields the syrup called *jaggery*, from 4 lb. of which 1 lb. of sugar is obtained, a single tree producing about 7 or 8 lb. of sugar annually. The operation of tapping for toddy spoils the fruit of the tree, which is small and much inferior to the African date. It is, however, eaten.—Another species, *P. paludosa*, the most gregarious of Indian palms, growing only 6 or 8 feet high, covers the landscape of the Sunderbunds with the liveliest verdure. *P. acaulis* and *P. furinifera* are also dwarf and closely allied common Indian species. *P. reclinata* is a characteristic palm of the Natal coast, and *P. spinosa* of Sierra Leone, &c. Some derive the origin of the colonnade pillar in architecture to the regular mode of its planting and the use of its stem in building, while in symbolic interest it stands second to no other plant. The symbol of beauty and of victory alike to Hebrews and Hellenes from the earliest times, it passed readily to the suggestion of victory over death and glorious immortality; hence alike the name *Phoenix* from the fabled bird, and the habit of representing angels and the blessed with palms in their hands. It was largely used also for decoration of festivals, and for strewing in processions. Christ's triumphal entry into Jerusalem is still commemorated on Palm Sunday (q.v.).

Date Plum (*Diospyros*), a genus of Ebenaceæ, important for timber (see EBONY, IRONWOOD) and fruit. The Common Date Plum or Pishamin, also called the European Lotus and the Date of Trebizond (*D. lotus*), is a tree of 18 to 30 feet in height, with oblong shining leaves and small reddish-white flowers, a native of the coasts of the Caspian Sea, Northern Africa, &c., but cultivated and naturalised in the south of Europe. It can also be grown in the south of England. Its fruit is of the size of a cherry, and in favourable climates larger, yellow, sweet, and astringent. It is eaten when over-ripe, like the medlar, or is used for conserves. This fruit has been supposed by some to be the *Lotus* (q.v.) of the Lotophagi. The Virginian Date Plum, or Persimmon (*D. virginiana*), is a tree of 30 to 60 feet high, with ovate oblong leaves and pale-yellow flowers, a native of the southern states of North America, where one tree often yields several bushels of fruit. The fruit is about one inch in diameter, with six to eight oval seeds. It is not palatable till mellowed by frost, and is sweet and astringent. A kind of beer or cider and an ardent spirit are made from it. *D. Mabola* is cultivated as a fruit-tree in Mauritius. *D. Kaki*, sometimes called the Keg-fig, is a native of Japan, which occasionally is kept in greenhouses in France and England. The sweetmeat called *Figues-cagues* is made from this fruit in France. The fruit of some other species is also edible—e.g. *D. decandra* of Cochinchina.

Datholite (Gr. *dathos*, 'turbid'), a mineral, colourless or inclining to grayish, greenish, white, or yellowish-gray colour, occurring both massive and crystallised in rhombic prisms, the edges and angles of which are commonly replaced by planes. It is composed of boracic acid, silica, and lime, with a little water. It has been found both in schistose and crystalline igneous rocks; and occurs near Edinburgh, in Norway, Italy, Connecticut, &c.

Datia, a native state of Bundelkhand, with a pop. (1881) of 182,598. The chief town, *Datia*, 125 miles SE. of Agra, on a rocky eminence, has a pop. (1881) of 28,346. It has several palaces, some now untenanted.

Datiscaceæ, a very small order allied to Begoniaceæ, including only four species, of remote distribution. *Datisca cannabina*, a plant much resembling hemp, is cultivated in Crete and Asia Minor for its hemp-like fibre, also as a source of yellow dyestuff. It has tonic properties.

Dative. See DECLENSION.

Datu'ra. See THORN APPLE.

Daub, KARL, a speculative theologian, was born 20th March 1765, at Cassel, studied philosophy and theology at Marburg, and became in 1795 professor of Theology at Heidelberg, where he died 22d November 1836. An earnest and singularly open-minded seeker after truth, although defective in the true historical sense, and not a robust and independent thinker, Daub laboured incessantly to find a sound basis for a reconciliation between religion and philosophy, and his successive writings reflect the whole development of prevailing philosophy from Kant to Hegel. Thus his *Lehrbuch der Katechetik* (1801) rests completely on Kant's fundamental principles; again, dominated by the influence of Schelling's 'philosophy of identity' are his *Theologumena* (1806) and *Einleitung* to Christian dogmatics (1810); while Schelling's transition to theosophy and to 'positive philosophy' is mirrored in Daub's *Judas Ischarioth* (1816), despite its eccentricities his best work. Hegel was called to Heidelberg in 1816, and henceforth it was his influence which was dominant over the receptive mind of Daub. In his *Dogmatische Theologie* (1833) and *Prolegomena* (1835), he attempts in the darkest language of the Hegelian dialectic a philosophical restoration of the dogmas of the church. Daub's *Theol.-philos. Vorlesungen* were collected by Marheineke and Dittenberger in seven volumes (1838-43). See Rosenkranz's eulogistic but uncritical *Erinnerungen* (1837), and D. F. Strauss, *Charakteristiken und Kritiken* (2d ed. 1844).

Daubenton, LOUIS JEAN MARIE, naturalist, was born at Montbar in Burgundy, 29th May 1716. He studied theology at the Sorbonne, but soon gave himself up to medicine and anatomy. In 1742 his old schoolfellow, Buffon, invited him to assist him in the preparation of his great work on Natural History, and Daubenton contributed richly to the first fifteen volumes of the *Histoire Naturelle*, until the jealousy of Buffon led to an estrangement. Daubenton now devoted himself almost entirely to his duties in the Jardin du Roi, where he was professor of Mineralogy. He was also for a time professor of Natural History in the College of Medicine. He contributed largely to the first *Encyclopédie*, and wrote many valuable *mémoires*. He died 31st December 1799.

Daubeny, CHARLES GILES BRIDLE, chemist and botanist, was born at Stratton in Gloucestershire, 11th February 1795. He devoted himself chiefly to the elucidation of natural phenomena by the aid of chemical science—his great work being *A Description of Active and Extinct Volcanoes* (1826). He also wrote on thermal springs. He

became professor of Chemistry at Oxford in 1822, of Botany in 1834, and was an F.R.S. Other works are an *Introduction to the Atomic Theory* (1831), *Lectures on Agriculture* (1841), and *Lectures on Climate* (1862). Daubeny died December 13, 1867.

D'Aubigné, JEAN-HENRI MERLE, a popular ecclesiastical historian, was born at Eaux-Vives, near Geneva in Switzerland, 16th August 1794, studied there and at Berlin—under Neander—and in 1818 became pastor of the French Protestant Church in Hamburg. In 1823 he was appointed court-preacher at Brussels; but after the revolution of 1830, he declined the post of tutor to the Prince of Orange, and returning to Geneva, took part in the institution of the new evangelical church, and filled the chair of Church History in its theological seminary until his sudden death, in the night of October 20-1, 1872. With the exception of some visits to England and Scotland, where he had numerous readers and admirers, and where he received the degree of D.C.L. from Oxford and the freedom of the city of Edinburgh, he remained constantly at Geneva. The work which has given him a widespread reputation is his *Histoire de la Réformation au Seizième Siècle* (1835-53); it has been translated into most European tongues, and has attracted more notice abroad than at home; it is written with a devout, fervid sympathy that is often eloquent, although the narrative is too graphic to be everywhere exact. Its popularity has been immense. Among his other writings are *Germany, England, and Scotland* (Lond. 1848); a vindication of Cromwell (1848); *Trois Siècles de Lutte en Ecosse* (1849); and *Histoire de la Réformation en Europe au Temps de Calvin* (1862-78).

D'Aubigné, THÉODORE AGRIPPA, a famous French scholar, was born on 8th February 1550, near Pons in Saintonge. At an early period he exhibited a remarkable talent for the acquisition of languages. Although born of a noble family, he inherited no wealth from his father, and consequently chose the military profession. In 1567 he distinguished himself by his services to the Huguenot cause, and was subsequently rewarded by Henry IV., who made him vice-admiral of Guienne and Brittany. His severe and inflexible character frequently embroiled him with the court; and after Henry's assassination (1610), he betook himself to Geneva, where he spent the remainder of his life in literary studies. He died April 29, 1630, leaving a worthless son, Constant, who was father of Madame de Maintenon. D'Aubigné's best-known work is his *Histoire Universelle, 1550-1601* (Amsterdam, 1616-20), which had the honour of being burned in France by the common hangman. D'Aubigné was possessed of a spirit of biting satire, as is proved by his *Confession Catholique du Sieur de Sancy*, and his *Aventures du Baron de Foënesté*. See his *Histoire Secrète, écrite par lui même* (1731); also French studies by Réaume (1883) and Morillot (1884).

Daubigny, CHARLES FRANÇOIS, landscape-painter and etcher, born in Paris in 1817, studied under his father, who was a miniature-painter, Paul Delaroche, and others, and from 1838 exhibited in the Salon, although his full recognition came only after the artist had reached his fiftieth year. He devoted himself to close and sympathetic study from nature, working much on the Seine in a house-boat, and developed a style of landscape art marked by singularly unaffected fidelity and originality. In 1853 he gained a first-class medal with his 'Pool of Gylien.' In 1857 he produced his 'Spring-time'; in 1861, 'The Banks of the Oise'; in 1872, 'Windmills at Dordrecht'; and in 1877, his large and very impressive 'Rising Moon.' His 'Sluices in the Valley of Optevos' (1855) and his 'Vintage'

(1863) are in the Luxembourg Gallery. He is also known as a book-illustrator and as a vigorous etcher, having produced over a hundred plates, some reproductions, others direct from nature, marked by great frankness of method and free painter-like quality. He died in Paris, 19th February 1878.

D'Aubusson, PIERRE, Grand-master of the order of St John of Jerusalem, surnamed 'the Shield of the Church,' was born of a noble French family in 1423. At an early age he entered the service of the Emperor Sigismund, and served under the Archduke Albrecht of Austria against the Turks. Returning to France, he served with the Armagnacs against the Swiss, and covered himself with glory at their defeat near St Jacob (1444). He next joined the order of the Knights of Rhodes, and rose rapidly into power, becoming grand-master in 1476. He laboured to bring about a confederation of all the Christian powers to counteract the triumph of the Turks that followed the fall of Constantinople. Mohammed II.'s career of conquest, which threatened to spread over Western Europe, was stayed alone by the obstinate bravery of D'Aubusson and his little colony of Christian soldiers in the island of Rhodes. In May 1480 an army of 100,000 Turks invested the town, but were forced to raise the siege after a month's desperate fighting, leaving behind them as many as 9000 dead. Mohammed was filled with fury, and a second attack was only averted by his death in 1481. D'Aubusson died in 1503.

Daudet, ALPHONSE, was born at Nîmes on May 13, 1840. His family had been in trade, but were not in good circumstances. He was, however, well educated at the Lyons Lycée, and was able when quite a boy to take the place of usher in a school at Alais, an employment of which, in *Le Petit Chose* and others of his works, he has given no cheerful reminiscences. He was only seventeen when, giving up his ushership, he set out for Paris with his elder brother, Ernest, who himself became a journalist and novelist of some mark. Alphonse (as also did Ernest) obtained an appointment as clerk or private secretary in the office of the Duke de Morny, of whom he has drawn a famous portrait in *Le Nabab*. Indeed, one of the main characteristics of M. Daudet's method, and one of the main reasons of his popularity with some, and his unpopularity with other readers, is the manner in which he seems to have utilised almost every circumstance and almost every acquaintanceship of his life in his books. M. Daudet's literary efforts, however, began with poetry; and his first book, in 1858, was entitled *Les Amoureuses*. He also devoted some not too successful years of experiment to theatrical work, writing by himself, or with a collaborator, *La Dernière Idole* (1862), *L'Œillet Blanc* (1865), *Le Frère Aîné* (1868), *Le Sacrifice* (1869), *Lise Tavernier*, and *L'Arlesienne* (1872), pieces of which the earlier were more successful than the later. Besides this, he contributed to many journals, especially the *Figaro*. In this form appeared some of his best work, the *Lettres de Mon Moulin* (collected 1869), *Robert Helmont* (1871), the *Contes du Lundi*, and others; and it was in these years that he conceived the charming extravaganza of *Tartarin de Tarascon*, a most amusing satire on the characteristics of the natives of the south of France, which he has followed up more recently with a second part, *Tartarin sur les Alpes*.

It was not, however, till many years after his literary beginnings that M. Daudet hit on the style which has made him popular and famous. He had sketched something of the kind early in *Le Petit Chose*, a book full of pathos and of reminis-

cences of his own early struggles. This pathetic quality is still further developed in *Jack* (1873), the story of an illegitimate child, part of the interest of which turns on the half-malicious sketches of certain literary Bohemians; and in *Fromont Jeune et Risler Aîné* (1874), where the devotion of a man of business to his firm, his wife, and his brother, meets in all three cases with an equally evil return. These have been followed by *Le Nabab* (1877), a transparent caricature of Morny and other well-known personages under the empire; *Les Rois en Exil* (1879), the chief parts in which are supposed to have been played also by actual persons; *Numa Roumestan* (1882), the hero of which was supposed to have some resemblance to Gambetta, and which at any rate is as remarkable in the serious way as *Tartarin* in the comic amongst satires on the 'meridional' type; *L'Évangéliste* (1883), in which the then new craze of the Salvation Army was introduced; *Sapho* (1884), a book somewhat out of M. Daudet's usual line, in which the mutual infatuation of a young man and a courtesan and artist's model is drawn with remarkable if not very wholesome power; and *L'Immortel* (1888), in which all the author's powers of ridicule, and all his practised skill in attacking individuals under a thin disguise, are employed to throw discredit on the French Academy. The vigour, and within certain limits, the versatility, of this series of novels is not denied by any one; but in addition to the personality already noticed, there has been charged against the earlier ones at least a following of Dickens, which can hardly be accidental, though it has been asserted to be so.

M. Daudet married early a lady of talent, who is understood to have rendered him much assistance in his literary work, and he formed for some time part of a group or coterie of remarkable literary characters, which included besides himself the Russian novelist Turgeneff, Gustave Flaubert, the brothers Goncourt, and M. Zola. He has published at various times autobiographic papers, which have been collected as *Trente Ans de Paris* (1887), and *Souvenirs d'un Homme de Lettres* (1889).

Daudnagar, a town in the Gaya district of Bengal, on the Sonne, 90 miles SW. of Patna. It is a wretched-looking place, with narrow, crooked lanes winding among miserable hovels. It possesses, however, a considerable river trade, and manufactures coarse fabrics both of wool and of cotton. Pop. 9870.

Daulatabad ('fortunate city'), a town and fort in the Deccan, within the Nizam's dominions, 28 miles NW. of Hyderabad. The fortress consists of a conical rock, 600 feet high, with a wide ditch and an outer wall nearly 3 miles in circumference. The place surrendered to the Mohammedans in 1294, and Shah Muhammad Tughlak (1324-51) thrice attempted to remove the seat of government thither from Delhi. The fortress has not been garrisoned now for many years, and the town has greatly decayed. Pop. 1243.

D'Aulnoy, MARIE CATHERINE JUMELLE DE BERNEVILLE, COUNTESS, was born about 1650, and died in 1705. She wrote many tedious and long-winded romances long consigned to safe oblivion. Of these may here only be mentioned *Hippolyte, Comte de Douglas* (1690). Equally worthless are her historical memoirs. But her fame rests securely on her *Contes des Fées*, which are written in a simple, bright, and charming style, not altogether unworthy of the inimitable master, Perrault. The White Cat, the Yellow Dwarf, Finette Cendron, and Le Mouton have for two centuries been naturalised in the nurseries of Europe, and are still familiar figures in pantomime.

D'Aumale. See AUMALE, DUC D'.

Daumer, GEORG FRIEDRICH, an able but eccentric German writer, was born in 1800 at Nuremberg, where for a time he was a professor in the gymnasium, and where Kaspar Hauser (q.v.) was committed to his care. Abandoning the pietism of his student days, he passed through Schelling's philosophy to a position of bitter antagonism to Christianity, which he wished swept from the face of the earth; but in 1859 he joined the Ultramontane party, and became one of its foremost champions. His many philosophical writings reflect his varying positions; so late as 1847 he endeavoured to prove that among the ancient Jews and the Christians of the first century human sacrifice obtained; from 1859 he expounded and defended the faith. His poetical works, especially *Mahomet* (1848) and the *Liederblüten des Hafis*, two graceful imitations of Persian poetry, have gained a high reputation. Daumer died at Würzburg, 14th December 1875.

Daumier, HENRI, a celebrated French caricaturist, was born at Marseilles in 1808. Fashion, tittle-tattle, scandal, politics, blemishes of figure, and oddities of character in turn inspired his inexhaustible genius for mockery. Few among his illustrious contemporaries escaped his pencil, and his caricatures had always some strikingly truthful feature about them. He made his début in the *Charivari*, in a series of sketches from *Robert Macaire*; and the revolution of 1848 suggested two of his most remarkable series—*Idylles Parlementaires* and *Les Représentants représentés*. In his old age Daumier became blind, and was befriended by Corot the landscape-painter. He died at Valmondois, 10th February 1879.

Daun, LEOPOLD JOSEPH, GRAF VON, commander-in-chief of the imperial troops during the Seven Years' War, was the son of Count Wierich Philipp von Daun, a distinguished officer in the Austrian service, and was born at Vienna, 24th September 1705. Entering his father's regiment, he acquired a reputation during the Turkish campaigns (1737-39). The war of the Austrian Succession also afforded him many opportunities of displaying that combination of valour and prudence for which he was famous. After the peace with Prussia in 1745, Daun fought against the French in the Netherlands (1746-48), and in 1754 received the dignity of field-marshal. Before this, he had, in spite of many obstacles, introduced into the imperial army a new military system, and reorganised the Military Academy at Vienna. At the commencement of the Seven Years' War he commanded the army of Moravia in 1757, and neutralised the defeat of the Austrians under General Browne near Prague, by driving Frederick the Great, who had beleaguered that city, as far as Kolin, and forcing him, after a hard-fought battle, to evacuate Bohemia. On the 14th of October 1758 he gained another victory over Frederick at Hochkirch, and came near to annihilating the Prussian army. In 1759, at Maxen, he compelled Fink, the Prussian general, with 11,000 men, to surrender. After this, however, he gained no important successes; Frederick began to understand the tactics of 'the Austrian Fabius Cunctator,' and to conduct his campaigns accordingly. Daun died 5th February 1766.

Dauphin (Lat. *Delphinus*), formerly the title of the eldest son of the French king, was originally that of the sovereign lords of the province of Dauphiné, who bore a *dolphin* as their crest. The last of these, the childless Humbert III., in 1343 bequeathed his possessions to Charles of Valois, grandson of Philippe VI. of France, on condition that the eldest son of the king of France should bear the title of Dauphin of Vienne, and govern the province. As late as the time of Louis

XI., the dauphin exercised almost sovereign rights; but after his time these were gradually abridged, until Dauphiné was placed under the same laws as the rest of the kingdom, and the title became merely honorary. After the revolution of 1830, it was abolished altogether. See DELPHIN CLASSICS.

Dauphiné, formerly a frontier province in the south-west of France, now forming the departments Drôme, Isère, and Hautes Alpes. Its capital was Grenoble, and it boasted its 'seven wonders'—remarkable caves, mountain-peaks, &c. Once the territory of the Allobrogi, after the fall of the Roman empire Dauphiné formed the southernmost part of the kingdom of Burgundy. It then passed under the dominion of the Franks, and after the dismemberment of the Carolingian monarchy, it became a portion of the new Burgundian kingdom of Arles. It then passed by legacy into the possession of the German emperor in 1032, and remained united with Germany till 1343, when it was presented to France (see DAUPHIN). There is a history by Chorier (2 vols. 1883).

Daurat, JEAN, a gifted French scholar, who played an important part in determining the course which his country's literature took at the time of the Renaissance. He was born about 1510, and became president of the Collège Coqueret, where he superintended the studies of Ronsard, Du Bellay, Baif, and Belleau. These poets, with whom he was united in the famous coterie of the Pléiade (q.v.), he carefully trained for the task of reforming the vernacular, and ennobling French literature by the imitation of Greek and Latin models. He wrote nothing of importance in French, but devoted himself to guiding and stimulating the other members of the Pléiade, in whose works his learning and enthusiasm bore rich and enduring fruit. He died in 1588.

Dauria, a mountainous region of south-eastern Siberia, between Lake Baikal and the river Argun, on the Chinese frontier.

Dauw. See HORSE, QUAGGA, ZEBRA.

D'Avenant, SIR WILLIAM, English poet and playwright, was born in 1606 at Oxford, where his father kept the Crown Tavern, a house at which Shakespeare was in the habit of stopping when on his journeys between London and Stratford. A story arose later that D'Avenant's birth was due to an intrigue between his mother and the great dramatist, but for this there seems to be no foundation, though apparently D'Avenant himself was willing enough to barter his mother's reputation for the credit of such a parentage. Aubrey tells us that D'Avenant would often say, when pleasant over a cup of wine, that it seemed to him that he wrote with the very spirit that Shakespeare did, and 'seemed contented enough to be thought his son.' In his twelfth year the precocious boy penned an *Ode in Remembrance of Master Shakespeare*, not printed, however, until 1638. After a short period of study at Lincoln College, he became page to Frances, Duchess of Richmond; next passed into the household of the aged poet, Fulke Greville, Lord Brooke, and in 1628 took to writing for the stage. During the next ten years he produced many plays, the least poor of which were *The Cruel Brother* (1630) and *The Wits* (1636). In 1638, at the request of the queen, he was appointed poet-laureate in succession to Ben Jonson. About the same time he lost his nose through an illness—a calamity which laid him open to the merriment of such wits as Suckling, Denham, and Sir John Mennis. He afterwards became manager of Drury Lane Theatre, but became embroiled in the intrigues of the Civil War, and was apprehended and flung into the Tower. He soon escaped to France, and returning, distin-

guished himself so much in the royalist cause, that he was knighted by Charles at the siege of Gloucester (September 1643). D'Avenant again got into difficulties, and was confined in the Tower for two years, when he was released, it is said, on the intercession of Milton. Once more he set about establishing theatrical representations, and in 1658 succeeded in opening a theatre. Two years earlier he had given what was practically the first opera in England, with Mrs Coleman as the first actress that ever appeared on an English stage. After the Restoration, D'Avenant was favoured by royal patronage, and continued to write and superintend the performance of plays until his death, April 7, 1688. His epic, entitled *Gondibert*, a feeble reaction from the romanticism of the Elizabethan poets, consists of fifteen hundred four-line heroic stanzas with alternate rhymes—a metre which the genius of Gray's *Elegy* can scarce save from the damning sin of monotony; much bepraised by its contemporaries, it now sleeps securely in the same oblivion with the author's *Madagascar*, and his great opera *The Siege of Rhodes*. A collected edition of his plays, with memoir, was edited by Logan and Maidment (Edin. 5 vols. 1872-74).—CHARLES D'AVENANT, his eldest son, was born in London in 1636, was educated at Balliol College, sat in parliament under James II. and William III., was commissioner of excise and joint-licenser of plays, under Anne secretary to the Commissioners for Union with Scotland, next inspector-general of imports and exports. He died 6th November 1714. Among his writings are *Discourses on the Publick Revenues and the Trade of England* (1698), and *A Discourse upon Grants* (1700).

Davenport, capital of Scott county, Iowa, on the Mississippi, opposite Rock Island (q.v.), 183 miles W. by S. of Chicago by rail. It is the seat of Griswold College (1839) and of several Catholic institutions, has extensive manufactures of flour, wooden and iron wares, and woollen goods, and is the shipping depot of a large grain trade. Pop. (1880) 23,830.

Daventry (pronounced *Daintry*), an ancient municipal borough of Northamptonshire, at the sources of the Avon and Nene, 12 miles W. of Northampton, and 4 NW. of Weedon by a branch line opened in 1888. It is well built on an eminence, and has two principal streets. Charles I. spent six days here in 1645 before the battle of Naseby. Pop. (1851) 4430; (1881) 3859. A mile to the east is Danes or Borough Hill, one of the largest Roman camps in the kingdom.

David, capital of Chiriqui (q.v.) in Panamá, lies in a fertile plain on the Rio David, which enters the Pacific 8 miles to the south. Stock-raising and the cultivation of tobacco are extensively engaged in, and there is a considerable trade. Pop. 9000.

David (Heb., 'beloved'), the second king over Israel. He sprang from a family of Judah, and was the youngest son of Jesse, a man of some substance at Bethlehem. He is described as a handsome youth, 'red-haired, with beautiful eyes, and fair of face,' when he first distinguished himself in Israel by slaying the Philistine giant Goliath. After this heroic deed, Saul took him to his court, and appointed him to a military command. According to another account (1 Sam. xvi. 14-23) it was his skill in playing the harp, and his being sent for to banish the melancholy of Saul by that means, that first led to his coming into contact with the moody king. He had soon to flee from Saul's court, as the king's jealousy of his supposed rival led him to seek David's life; but, by the craft of his wife Michal, Saul's daughter, and the friendship of Jonathan, Saul's son, he escaped, and fled to the

country of the Philistines, where, however, he found refuge only for a short time. In the cave (or hill-fort) of Adullam, near Gath, he gathered a troop of 400 freebooters, which afterwards increased to 600, and with which he ranged through the country between Philistia and the Dead Sea, never attacking his king or countrymen, but always their enemies on the west and south, and levying contributions from the people of Judah for his protection of their flocks. The expeditions which Saul led against him frequently put him to great straits, and the difficulty of controlling his irregular force without assuming the offensive against 'the Lord's anointed' becoming ever greater, David left Judah, and became a vassal of the Philistine king of Gath, occupying for a year and four months the town of Ziklag in the desert to the south. After the death of Saul and Jonathan at Gilboa, he reigned seven and a half years in Hebron over the tribe of Judah, while Ishbosheth, Saul's son, ruled the rest of Israel with the help of Abner—probably as a vassal of the Philistines. On the death of Ishbosheth, all Israel chose David as king. He conquered the independent city of Jebus (Jerusalem), the strongest natural fortress in the country, and made it the political and religious centre of his kingdom, building, with the help of Tyrian artificers, a palace for himself on its highest hill Zion (the 'city of David'), and placing the Ark of the Covenant (q.v.) there under a tent—to be replaced under his successor by a temple, for which large collections of materials were made in David's reign. The nucleus of his army consisted of his old bodyguard of 600 *gibbōrim* (or 'heroes'), from which the officers of the general levy were drawn. A plan is described in Chronicles by which 24,000 were put under arms each month out of the 288,000 able-bodied men who were the fighting strength of the country. There was an additional regiment of life-guards, mostly foreigners ('*Crēthi* and '*Plēthi*'). In the course of a few years the conquest of the Philistines, Moabites, Arameans, Edomites, and Ammonites reduced the whole territory from Egypt to the Euphrates. During the siege of Rabbah, the Ammonite capital, David committed the greatest sin of his life, his adultery with Bathsheba and indirect murder of her husband. Henceforward 'the sword never departed from his house.' The last years of his long reign of thirty-two years in Jerusalem were troubled by popular disaffection, of which his favourite son Absalom availed himself to attempt a revolution, which nearly succeeded in placing him on the throne, but cost him his life, to David's excessive grief; and shortly before David's death—which was at earliest 1018, at latest 993 B.C.—another such unsuccessful attempt was made by another son, Adonijah, who was aggrieved at the choice of Solomon as his father's successor.

David is by far the greatest of the kings of Israel. The spirit of his rule is beautifully expressed in his 'last (poetic) words,' in 2 Sam. xxiii. 1-7. His personal courage, his skill and unvarying success in war, his foresight and circumspection in government, and his readiness to sacrifice merely personal ends to the welfare of his whole people are especially conspicuous. He 'executed judgment and justice unto all his people.' The foundation of his rich and complex character was his strong faith in Jehovah his God. It was this that distinguished him from Saul as 'the man after God's own heart.' He was no saint in the Christian sense, and in his lapses from veracity, his polygamy, and his cruel treatment of conquered enemies, he followed the customs of his time. But the same unvarnished history which is the sole authority for the dark sides of his character is equally to be believed in its presentation of the brighter sides, and does not support the unfavourable judgment of David expressed by

Bayle, Voltaire, Renan, and others, who would make him out either a licentious, cruel, and hypocritical despot, or simply a child of nature gifted with an equal share of great virtues and great vices.

The historical picture of David fully supports the tradition that 'the sweet singer of Israel' was the greatest poet of his time, and the founder of the sublime religious lyric poetry of the Hebrews, though many of the Psalms are rather productions of the Davidic spirit than of David's own pen. 'At an earlier date,' says Cheyne, 'much labour was rather unprofitably spent in defending the Davidic authorship of psalms transparently non-Davidic. An opposite tendency now prevails. Of the three most distinguished writers, Ewald acknowledges only eleven entire psalms and some fragments of psalms as Davidic, Hitzig fourteen, and Delitzsch forty-four. All of these agree as to the Davidic authorship of Psalms iii., iv., vii., viii., xi., xviii., xix. 1-7, and two out of three as to that of Psalms ix., x., xii., xiii., xv.-xviii., xix. 8-14, xxiv., xxix., xxxii., ci. Kuenen, however, will admit no Davidic psalm, though Davidic passages may have been inserted. In any case, it is quite certain that there are none in the last three books, and the probability is that Ewald's is the most conservative view of the headings at present tenable.'

The reign of David not only determined the political life of Israel, but also its conception of ideal glory. As the succeeding ages grew darker and more troubled, believing hearts in Israel turned back to those days of the kingdom's glory; men felt that only a king like David could restore the theocracy ordained of Jehovah; he formed the prototype for the Messianic hope that Jehovah would send a son of David, who should redeem Israel.

David, or DEWI, ST, the patron saint of Wales, first mentioned in the *Annales Cambrie* (10th century) as having died in 601, Bishop of Moni Judeorum, or Menevia, afterwards St David's. He presided over two Welsh synods, at Brefi and at 'Lucus Victoriae.' A rich legendary history supplements these meagre but authentic details. Rhygyfarch tells that he was grandson of King Ceredig, and a pupil of Paulinus, that he journeyed through Wales preaching and working miracles, visited Jerusalem, and denounced Pelagianism at Brefi with such triumphant loudness that he was made by acclamation metropolitan Archbishop of Wales. Giraldus follows Rhygyfarch in his life, and Geoffrey of Monmouth supplements it further by making David the uncle of King Arthur, and locating the metropolitan see first at Caerleon, whence it was transferred by David, with the sanction of Arthur, to Menevia.

David I. (often called ST DAVID), king of Scotland, was the youngest of the six sons of Malcolm Ceannmor and St Margaret (q.v.). Born in 1084 he was sent in 1093 to England along with his sister Matilda (who in 1100 married Henry I. of England), and remained for several years at the English court—a residence that powerfully affected his after career. There, as his contemporary William of Malmesbury puts it, he was 'polished from a boy' until he 'had rubbed off all the rust of Scottish barbarity.'

In 1107, when his elder brother Alexander succeeded to the throne, David, by express bequest of Eadgar, became Prince of Cumbria, a territory which, besides part of the modern shire of Cumberland, included the whole district between the Tweed and Solway and the Firths of Forth and Clyde, except the shires of Haddington, Edinburgh, and Linlithgow. Over the greater part of this domain he appears to have held absolute sway. Alexander seems at first to have been inclined to

dispute David's right to the district, but the success of his claim was secured without contest by the influence of the great Norman barons who had by this time acquired extensive possessions in the south of Scotland, and to whom David's English training rendered him peculiarly acceptable. By David's marriage in 1110 to Matilda, widow of Simon de Senlis, and heiress of Waltheof, Earl of Northumberland, he still further increased his power, becoming Earl of Huntingdon and Earl of Northampton.

In 1124 he succeeded his brother on the Scottish throne, but had in 1130, and again in 1137, to fight for his crown against the heirs of the old Celtic dynasties supported by the wild tribes of the north and west. On both occasions the Anglo-Norman chivalry which David had gathered around him gave him decisive victories. Having sworn, along with the other great barons of England, to maintain the right of his niece, Matilda, to the English crown, David took up arms on her behalf in 1135 when Stephen mounted the English throne, and penetrated into England as far as Durham, where at a meeting between him and Stephen peace was restored by the grant of the earldom of Huntingdon, and the promise of the earldom of Northumberland, to David's son Henry. In 1138 the war was, however, renewed, and the king of Scots, deserted by Bruce and others of his Anglo-Norman vassals who owned large estates in England as well as in Scotland, was signally defeated at the 'Battle of the Standard,' near Northallerton. The next year, a second peace was concluded, when the promised earldom of Northumberland was bestowed on Prince Henry.

The rest of David's reign—which marks the end of Celtic and the beginning of Feudal Scotland—was devoted to the accomplishment of the great designs begun by his father and mother, and continued by his two predecessors—the union of the different races of Scotland into one nation, and the civilisation of the people. How well he succeeded may be traced in the two centuries of prosperity that followed his reign. By the introduction of the feudal system, and the promulgation and vigorous personal superintendence of the working of wise laws, he endeavoured to secure the peace and safety of the country; and he looked for aid in this work to the Anglo-Normans whom he had brought from the south. By the erection of burghs he promoted the trade, manufactures, and commerce of the nation, and laid the foundations of its freedom. In his civilising efforts he depended also largely on the church, the extension and influence of which he greatly fostered and encouraged. Immediately after he became Prince of Cumbria he restored the fallen bishopric of Glasgow, and after his accession he founded and endowed the bishoprics of Ross, Aberdeen, Caithness, Brechin, and Dunblane; besides enriching the previously established sees of St Andrews, Moray, and Dunkeld, and reviving the old see of Galloway (Whithorn). He also founded or restored the abbeys of Kelso, Jedburgh, Melrose, Newbattle, Holyrood, Cambuskenneth, and Kinloss, as well as a number of minor religious establishments. So far indeed did this process of endowment go, that according to Bellenden, 'the crown was left indegent throw ampliation of gret rentis to the kirk,' a state of matters that led James I. (of Scotland) to remark, while standing by David's tomb at Dunfermline, that 'he was ane sair sanct for the crown.' On the other hand one who was a hard judge of monarchs—George Buchanan—said with much more truth, that 'if men were to set themselves to draw the image of a good king, they would fall short of what David showed himself throughout the whole course of his life.' Though King David

is often called St David, he was never formally canonised; but his name was inserted in the calendar prefixed to Laud's Prayer-book for Scotland, printed at Edinburgh in 1637.

King David died at Carlisle, 24th May 1153. His son Henry had died in the previous June, and he was succeeded by his grandson, Malcolm, then in his twelfth year.

The oldest Scottish painting now known to exist—an illuminated charter to the monks of Kelso, written in 1159—preserves rude miniatures of the young king Malcolm and his saintly grandfather. It is preserved at Floors Castle, and engraved in fac-simile in the *Liber S. Marie de Calchou* (Bannatyne Club, 1846). See also Innes's *Scotland in the Middle Ages* (1860); Robertson's *Scotland under her early Kings* (1862); and Skene's *Celtic Scotland* (1876). The remains of David's legislation, including the interesting code of the *Leyes Burghorum*, have been carefully collected in the first volume of *The Acts of the Parliaments of Scotland* (1844).

David II., only son of King Robert Bruce, was born at Dunfermline, 5th March 1324, and was married in 1328 to Edward II.'s daughter, Joanna. In June 1329 he succeeded his father, and in November 1331 was crowned, with his child-queen, at Scone. In 1334 the success of Edward Baliol (q.v.), and Edward III.'s victory at Halidon Hill, forced David's guardians to send him and his consort to France, whence by the triumph of the national party he was permitted to return in 1341. Five years later, in fulfilment of his alliance with France, he invaded England, but at the battle of Neville's Cross, near Durham, was utterly routed by the Archbishop of York, 17th October 1346. For eleven years he remained a prisoner, in or near London, and at Odiham, in Hampshire; at length, in 1357, he was released on promise of a heavy ransom (100,000 marks), whose non-payment involved him in shameful dependence on England. In 1363 he actually proposed to his parliament that Edward III.'s second son should succeed him on the Scottish throne; and though the proposal was curtly rejected, the intrigue between the two kings was ended only by David's death at Edinburgh Castle, 22d February 1371. He was not forty-seven years old, yet his reign had lasted more than forty-one years—a reign as inglorious as it was long, but still of great moment to Scotland, since, 'from a war of conquest and patriotic resistance, the struggle had died into a petty strife between two angry nations, a mere episode in the larger contest which it had stirred between England and France.' Queen Joanna dying in 1362, David next year had married Margaret Logie, a comely widow, whom he divorced in 1369. By neither marriage had he any issue, so was succeeded by his sister's son, Robert II.

David, FÉLICIEN, a French composer, was born 8th March 1810, at Cadenet, in the department of Vaucluse. He was first a chorister in the cathedral of Aix, then at the age of twenty entered the Paris Conservatoire. He threw himself earnestly into the social speculations of his day; became an ardent disciple of St Simon, and afterwards of *Enfantin*; and finally, on the break-up of the brotherhood in 1833, he betook himself, along with several of his fellow-dreamers, to the East. The little knot of enthusiasts reached Constantinople, whence they made their way to Smyrna and Cairo. As they had no means, they suffered greatly from want, sickness, and ill-usage. In 1835 he returned to Paris, and published his *Mémoires Orientales* for the pianoforte. They were unsuccessful; and David remained in obscurity till 1844, when he brought out at the Conservatoire his *Désert*, a grand *Ode-symphonic*, as he called it, the words of which were furnished by his friend and fellow-wanderer, Auguste Colin. Its success was sudden

and complete. David was declared a master at once, and his *Désert* was performed in all the theatres. Subsequently, he travelled through Belgium and Germany, and was everywhere greeted with applause. Less successful works were—*Moïse sur le Sinaï* (1846), *Christophe Colomb* and *Le Paradis* (1847), *La Perle du Brésil* (1851), *Herculanum* (1859), and *Lalla Rookh* (1862). He composed also a quartette for strings, a nonette, a symphony, and songs. Appointed an officer of the Legion of Honour in 1862, and in 1869 librarian to the Paris Conservatoire de Musique, David died 29th August 1876.

David, FERDINAND, a distinguished violin virtuoso, born 19th June 1810, at Hamburg, was from thirteen a pupil of Spöhr at Cassel, and became in 1836 concertmeister at Leipzig, which place he kept till his death at Klostern in the Grisons, 19th July 1873. His remarkable talent for teaching his instrument he showed after the establishment of the Leipzig Conservatorium, and many of the best violinists of his time were his pupils. His compositions were equally esteemed.

David, GERHARD, painter, born about 1450, at Oudewater in Holland, in 1484 entered the Painters' Guild of Bruges, of which he became dean in 1501. He died in Bruges in 1523. The National Gallery, London, contains an admirable example of his work in 'A Canon and his Patron Saints,' a wing from an altarpiece; and among his other pictures are a Madonna, in the museum at Rome; a Crucifixion, in Berlin; and a Baptism of Christ and a Descent from the Cross, both at Bruges.

David, JACQUES LOUIS, historical painter, was born at Paris, 31st August 1748. He received his first instruction from Boucher, his uncle, and at the age of twenty-one became a pupil of Vien. After several unsuccessful attempts he gained the 'prix de Rome' in 1774, and in the following year he settled in Rome, where Vien had been appointed director of the French Academy. Here he produced little in colour, but devoted himself to making accurate drawings from the antique. Six years later he returned to France, and his 'Belisarius' (1780) procured his admission to the Academy. Soon afterwards he married, and again visited Italy and also Flanders. It is in the works executed during this period, such as the celebrated 'Oath of the Horatii' (1784), 'The Death of Socrates' (1788), 'The Loves of Paris and Helen' (1788), and 'Brutus condemning his Son' (1789), that the classical feeling—founded upon sculpture and possessing much of its hardness as well as its clear-cut accuracy of form which was the painter's chief characteristic—is first clearly visible. During the Revolution David entered with enthusiasm into the political conflicts of the period. In 1792 he became a representative for Paris in the Convention. He voted for the death of Louis XVI., and was a member of the Committee of Public Safety; and he was the artistic director of the great national fêtes of the republic, which were founded on classical customs. After the death of Robespierre he was twice imprisoned, and narrowly escaped with his life. On his release in 1795 he devoted himself to his art, producing 'The Rape of the Sabines' (1799), which is usually ranked as his masterpiece. He was an original member of the Institute, and in 1804 was appointed first painter by Napoleon I. After the restoration of the Bourbons, he was banished in 1816 as a regicide, and retired to Brussels, where, having declined an invitation to undertake the directorship of Fine Arts at Berlin, he died, 29th December 1825.

David's productions are distinguished by a certain austere dignity of conception and by elaborate

accuracy of form. On the other hand they are often cold and unreal in sentiment, unpleasantly monotonous in colouring, and defective in their arrangements of light and shade. His art and example exercised the most powerful effect upon the French school of painting; among his pupils were Girodet, Gros, Léopold Robert, Ingres, and Gérard; and the classicism which he introduced reigned supreme until the rise of the Romantic school headed by Géricault and Delacroix. The influence which in his later days he exercised upon the school of Belgium was hardly less marked and powerful. Fourteen of his works are in the Louvre, and five—including 'Bonaparte crossing the Alps' (1805)—are at Versailles. See *Le Peintre David*, by his grandson, J. L. Jules David (1880).

David, PIERRE JEAN, a French sculptor, known as David d'Angers, was born at Angers, 12th March 1789. In spite of the opposition of his father, a talented wood-carver, he resolved to become an artist; and after studying in the art schools of his native town, he made his way on foot to Paris in 1808, and placed himself under Jacques Louis David, the painter. In 1811 his 'Death of Epaminondas' gained the 'grand prix,' and David proceeded to Rome, where, though he became intimate with Canova, he preserved his own individuality, and produced works modern in feeling and full of strongly marked character. In 1816 he returned to France. A statue of the Great Condé, which he executed about this time, established his reputation. In 1826 he was named a member of the Institute, and appointed a professor in the School of the Fine Arts; in 1828, and again in 1834, he visited Germany. During the July revolution, David fought in the ranks of the people, and in consequence he was employed by the new government to execute the pediment of the Pantheon (1835-37). By many it is considered his *chef d'œuvre*. In 1848 the well-known republicanism of the artist procured for him the honour of a seat in the Constituent Assembly. After the *coup d'état* he was sent into exile, and went to Greece, but soon after returned to France. He died 5th January 1856. In the museum of Angers about two hundred of David's works in relief and the round are preserved, as well as some four hundred of his medallions and many of his drawings. Besides its artistic value this collection possesses the greatest historical interest, as including portraits of the most eminent of the sculptor's contemporaries. See his *Life* by Joutin (1878).

Davidson, ANDREW BRUCE, D.D., LL.D., born in Aberdeenshire in 1831, was educated at Marischal College, Aberdeen, and at the Free Church College, Edinburgh, where in 1863 he was appointed to the chair of Hebrew and Old Testament exegesis. In this capacity he has since laboured quietly, but has exercised a quite unusual personal influence upon his students, and through them has done much to leaven the Free Church with a critical spirit that is fearless in method, but reverent in spirit, and in the best sense conservative of the real essentials of faith. With a singular reticence and self-repression, Dr Davidson, beyond an occasional sermon or article in the *Expositor*, has seldom spoken outside his lecture-room, and has published little, and that rather suggestive than demonstrative of his power as an exegete. He was throughout a member of the Old Testament Revision Committee. His books are a short treatise on Hebrew accentuation (1861), an unfinished commentary on Job (1862), a thoroughly serviceable *Introductory Hebrew Grammar* (1874), and admirable short school Commentaries on Job, the Epistle to the Hebrews, and Ezekiel.

Davidson, SAMUEL, D.D., LL.D., one of the ablest of English exegetes, born near Ballymena in Ireland in 1807, educated at the Royal College of Belfast, entered the Presbyterian ministry, and was called in 1835 to the chair of Biblical Criticism in his own college. Becoming a Congregationalist, he was called in 1842 to the chair of Biblical Literature and Oriental Languages in the Congregationalist College at Manchester; a position which he was compelled to resign on the publication of the volume which he contributed to a new edition of Horne's *Introduction*, though his tone is reverent, and his theological opinions are moderately conservative. He was a member of the Old Testament Revision Committee. His works are *Sacred Hermeneutics* (1843), *Lectures on Ecclesiastical Polity* (1848), *An Introduction to the New Testament* (3 vols. 1848-51), *Treatise on Biblical Criticism* (2 vols. 1852), *The Hebrew Text of the Old Testament revised* (1855), *Text of the Old Testament, and the Interpretation of the Bible*, for the new edition of Horne's *Introduction* (1856); *Introduction to the Old Testament* (3 vols. 1862), *An Introduction to the New Testament* (2 vols. 1868), *On a fresh Revision of the English Old Testament* (1873), *The Canon of the Bible* (1877), *The Doctrine of Last Things* (1883); besides translations of the New Testament from Tischendorf's text, of Gieseler's *Church History*, and Fürst's *Hebrew Lexicon*.

Davies, SIR JOHN, poet and statesman, was born of a good family at Tisbury, Wiltshire, in 1569. At sixteen he entered Queen's College, Oxford, whence he passed to the Middle Temple. He was called to the bar in 1595, but was disbarred three years later for breaking a stick in the dining-hall over the head of a wit whose raillery had provoked him. He returned to Oxford, and there wrote his long didactic poem on the immortality of the soul, *Nosce Teipsum*, dedicated to Queen Elizabeth, in 1599. Spite of the difficulties of a formal poem upon such a theme, it is a fairly successful performance, clear, vigorous, and sincere, though quite devoid of passion or imagination. The verse is that of the *Annus Mirabilis* and Gray's *Elegy*. Davies had already published in 1596 his *Orchestra, or a Poeme of Dancing*, 'a sudden rash half-capreol of my wit.' It is written in seven-line stanzas in imitation of Spenser, and is a graceful and harmonious poem on the conceit that all natural phenomena are subject to a regulated motion here called dancing. In 1599 Davies published also his *Hymns to Astraea*, a collection of clever acrostics each making the name Elizabeth Regina. He contributed also to *England's Helicon* and to Francis Davison's *Poetical Rhapsody*. In 1601, after ample apologies, Davies was readmitted to the society of the Middle Temple, and was returned to parliament for Corfe Castle. On the death of Elizabeth he accompanied Lord Hunsdon in his journey to the Scottish court, and quickly came into favour with James I., who sent him in 1603 as solicitor-general to Ireland. Three years later he was appointed Irish attorney-general and serjeant-at-law, and was raised to the honour of knighthood. He sent many statesmanlike letters and reports to Cecil, supported severe anti-Catholic and repressive measures, and took an important part in the plantation of Ulster. He sat in the Irish parliament for Fermanagh, and was for some time its speaker; but was returned to the English parliament in 1614 for Newcastle-under-Lyne, and resigned his office at Dublin in 1619, continuing to practise as king's serjeant in England. He was nominated chief-justice in November 1626, but died suddenly of a fit of apoplexy about a month after. He collected his three chief poems into one volume in 1622. His complete works were collected by Dr

Grosart in the 'Fuller Worthies Library' (3 vols. 1869-76).—His widow, Eleanor Touchet, daughter of Baron Audley, whom he had married in 1609, married again and survived till 1652. She was crazy enough to imagine herself a prophetess; but her exertations brought her nothing save fine, imprisonment, and ridicule (see ANAGRAM).—With Sir John Davies must not be confounded John Davies of Hereford (1565-1618), poet and writing-master, whose poetry is not without merit, although prolix and tedious. His chief long poems are *Miram in Modum*, *Microcosmus*, and *Summa Totalis*. In his collection of three hundred poor epigrams (about 1611) is one addressed 'To our English Terence, Mr Will. Shake-speare.' His works were collected by Dr Grosart in two volumes in 1873.

Davila, ENRICO CATERINO, a celebrated Italian historian, was born at Pieve di Sacco, in the vicinity of Padua, in 1576. When seven years old, he was taken to France for his education, and at the age of eighteen he entered the service of Henry IV., which he afterwards exchanged for the military service of Venice. In 1631 he was shot by an assassin on his way to Crema, to take command of the garrison. Davila has been rendered famous by his great work, entitled *Storia delle Guerre civili di Francia* (1630; best ed. Milan, 1807), a history comprising that eventful period from the death of Henry II. (1558) to the peace of Vervins in 1598. There is an English translation by Aylesbury and Cotterell (1647; new ed. 1678).

Da Vinci. See LEONARDO DA VINCI.

Davis, JEFFERSON, president of the Confederate States, was born in Christian county, Kentucky, June 3, 1808. He studied at Transylvania College, and at the United States military academy at West Point, where he graduated in 1828. Entering the army, he served in several frontier campaigns, but resigned his commission in 1835. He entered congress in 1845 as a representative from Mississippi, and served in the Mexican war (1846-47) as a colonel of volunteers, in which capacity his bravery won high commendation. He was appointed to the United States senate in 1847, and re-elected in 1848 and 1850; in 1851 he made an unsuccessful canvass for the governorship of Mississippi. From 1853 to 1857 he was Secretary of War under the presidency of Franklin Pierce. After this he returned to the senate, where he succeeded Calhoun as the leader of the extreme State Rights party. He was the author of the seven resolutions passed in May 1860 by the senate, in which it was virtually asserted that neither congress nor the legislature of any territory could prohibit slavery in such territory, but that both were bound to protect property in slaves; that the people of no territory could prohibit slavery until after the adoption of a state constitution; and that congress could neither prohibit nor permit the institution of slavery in any state applying for admission into the Union. The refusal of the lower house of congress to concur in these resolutions led to great popular agitation in the South. The failure of the Democratic National Convention at Charleston to adopt resolutions embodying substantially the same ideas had already (May 1, 1860) caused the disruption of that body and of the Democratic party; and the election of Lincoln, the Republican candidate, to the presidency was an immediate result of this division of the Democrats. In January 1861 the state of Mississippi seceded from the Union, and as a consequence Davis left the senate. A few weeks later he was chosen president of the Confederate States under their provisional form of government. In the November following he was without opposition elected president of the confederacy for a term of six years. The history of his presidency is that

of the war of 1861-65 (see UNITED STATES). In May 1865, after the collapse of his government, Davis was captured by a force of Union cavalry. After two years' imprisonment in Fort Monroe he was released on bail, and though he had been indicted for treason, was never brought to trial, a *nolle prosequi* being entered in his case in 1868. After 1879 he resided on an estate bequeathed to him in Mississippi; and in that year he was specially excepted in a bill to pension veterans of the Mexican war. In 1886 he dedicated a monument to Confederate soldiers in Montgomery, Alabama. He published *The Rise and Fall of the Confederate Government* (2 vols. 1881). See his *Life by Alfriend* (1868) and *Pollard* (1869); also Craven, *The Prison-life of Jefferson Davis* (1866).

Davis, JOHN, an English navigator, was born at Sandridge, near Dartmouth, about 1550, and is principally distinguished for having undertaken in 1585 and the two following years three voyages to the Arctic Seas in search of a north-west passage. In the last voyage, he sailed with a bark of apparently not over twenty tons, as far north as the 73d degree of latitude, and discovered the strait which bears his name. He next made two ill-fated voyages towards the South Seas, and as pilot of a Dutch vessel bound to the East Indies. In his last voyage as pilot of an English ship of 240 tons he was killed in a brush with some Japanese pirates at Bintang, near Singapore, 30th December 1605. His writings, *The World's Hydrographical Description* (1595) and *The Seaman's Secrets* (1594), were edited for the Hakluyt Society in 1880 by Captain A. H. Markham, with a biographical introduction. Here it is pointed out that Davis is often confounded with John Davis of Limehouse, a navigator to the East Indies, who died at Batavia in 1622, and published in 1618 *A Ruter or Briefe Direction for Readie Sailings into the East India*, which will be found in Part I. of *Purchas his Pilgrimes*.

Davis, THOMAS, Irish poet and patriot, was born at Mallow, 14th October 1814, the son of an army surgeon. At Trinity College, Dublin, he read hard and graduated, and, after spending nearly three years in London and on the Continent, was called to the bar after his return to Dublin in 1838. Next year, though a Protestant, he joined the Repeal Association, and in 1841 became for a short time joint-editor with John Dillon of the *Dublin Morning Register*. In the July of 1842, with Dillon and Duffy, he founded the famous *Nation* newspaper, the chief end of which was 'to direct the popular mind and the sympathies of educated men of all parties to the great end of nationality.' It was the first time that conspicuous literary ability had been devoted to the cause, and ere long its bright vigorous articles and stirring as well as pathetic songs, many of them from the pen of Davis himself, made the pages of the *Nation* dear to Irishmen all over the island. Davis started a projected series of Irish orators with the *Speeches of Curran* (1844), and wrote a good 'Essay on Irish Songs' for Barry's *Songs of Ireland* (1845). But his bright and promising career was soon closed by his premature death of fever, in Dublin, September 16, 1845. His *Poems* were published in 1846 in 'Duffy's Library of Ireland'; his *Literary and Historical Essays* in 1847.

Davis Strait washes the western coast of Greenland, and connects Baffin Bay with the Atlantic Ocean. At its narrowest point, immediately north of the Arctic circle, it measures about 200 miles across. In 1888 the identity between Ginnunga Gap, referred to in the Sagas, and the present Davis Strait was demonstrated.

Davits, on shipboard, are upright columns of forged iron, curved at their upper ends, which pro-

ject, or may be made to project, over a vessel's side or stern, and are used as a kind of crane to hoist, suspend, or lower a boat. They are arranged in pairs, one for each end of the boat. See BOAT-LOWERING GEAR.

Davitt, MICHAEL, founder of the Irish Land League, the son of a Mayo peasant, was born near Straid, County Mayo, in 1846. Evicted from their small holding, the family emigrated to Hastingden in Lancashire (1851); and here six years later the boy lost his right arm through a machinery accident in a cotton-factory. In 1866 he joined the Fenian movement, the result being that he was sentenced in 1870 to fifteen years' penal servitude. He was released in 1877; and, supplied with funds from the United States, began some two years later an anti-landlord crusade in Ireland, which culminated in the foundation of the Irish Land League (October 21, 1879). Davitt was thenceforward in frequent collision with the government, and from February 1881 to May 1882 was imprisoned in Portland for breaking his ticket-of-leave. His *Leaves from a Prison Diary* were published in 1885. The views of the 'Father of the Land League' on the subject of land therein take a Socialistic form, and on the question of land nationalisation he found himself in opposition to the Parnellites. But his zealous support of the cause of Home Rule more than counterbalanced this difference of opinion; while his general popularity in Ireland was proved by the national present of 'Land League Cottage' near Dublin on his marriage in 1887. His Life has been written by D. B. Cashman (Glasgow, 1882).

Davôs' (Romansch *Tarant*) is a small valley lying amongst the Alps of the Eastern Grisons, 16 miles SE. of Coire. The village of Davos-Platz stands 5105 feet above sea-level; but the valley, inclosed by lofty hills, has become famous as a health-resort in winter, especially for such as suffer from chest disease. The air is still and dry, and throughout the winter there is a great deal of bright, warm sunshine. Till lately mere out-of-the-way hamlets, the villages of Davos-Platz and Davos-Dörfli have now eight or ten hotels, numerous villas and chalets, several doctors, and daily posts. The 3561 inhabitants of the valley, which till 1848 was one of the 26 independent republics of the Grisons, are mostly German Protestants. See English works on the place by Wise (1881) and Muddock (1884).

Davoût (not DAVOUST, as commonly written), LOUIS NICOLAS, a French marshal, was born 10th May 1770, at Annoux, in the old province of Burgundy; was educated along with Bonaparte at the military school of Brienne; and in 1788 became lieutenant in a cavalry regiment. During the revolutionary wars he rose to the rank of general. He accompanied Bonaparte to the East, where he mainly contributed to the victory at Aboukir, and otherwise distinguished himself both in Upper and Lower Egypt. On his return to France, he was named general of division in 1800, commander-in-chief of the consular grenadier guards in 1800, and marshal of the empire in 1804. He acted a brilliant part in the great victories obtained by the French at Austerlitz (1805) and Auerstädt, and was created by the emperor Duke of Auerstädt (July 2, 1808). On the renewal of the war with Austria in 1809, Davoût rendered useful service at Eckmühl (22d April); and at Wagram, where he commanded the right wing, he succeeded in turning the enemy's left, and so first checked the Austrians' attack. In 1811 he was created Prince of Eckmühl. Appointed governor of Poland, he ruled that country in a spirit of the harshest despotism, and provoked the reproaches of the emperor, but,

nevertheless, did not forfeit his system. In the Russian campaign of 1812 he gathered fresh laurels on the fields of Moliliev and Vitebsk (27th July). After the retreat from Moscow, Davoût became governor-general of the Hanse towns, and established himself at Hamburg, where he gallantly maintained himself till the first restoration of the Bourbons. On the return of Bonaparte from Elba, Davoût was appointed war-minister, and as such showed a remarkable genius for the rapid organisation of troops and supplies. After the battle of Waterloo, he received the command of the remnant of the French army under the walls of Paris. He would have continued the contest had he not been ordered by the Provisional Government in the capital to conclude a military convention with the Allies. In 1819 he was made a peer of France. His death took place June 1, 1823. Firmness of character and dauntless courage were Davoût's leading characteristics; but his military severities often went the length of harshness, and even cruelty, while his rapacity had in it something akin to barbarism. See his *Correspondance* (4 vols. 1885), and his *Life* by Chénier (1886), by his daughter, the Marquise Blocquville (3 vols. 1879-80), and by Montegut (1882).

Davy, Sir Humphry, one of the greatest chemists, was born 17th December 1778, at Penzance, Cornwall, where his father was a carver in wood. At the school at Penzance, and afterwards at Truro, he developed a taste for storytelling, poetry, and angling, and for experimental science, in which he was aided by Dunkin, a saddler. In 1795 he became apprentice to a surgeon and apothecary in Penzance, wrote verses, and indulged in chemical experiments. He at the same time entered upon a course of study all but universal. 'Speculations on religion and politics, on metaphysics and morals, are placed in his notes in juxtaposition with stanzas of poetry and fragments of romance.' The study of natural philosophy brought him near to that department which was to be his own; but it was not till he had reached his nineteenth year that he entered seriously upon the study of chemistry. He now made the acquaintance of Dr Beddoes (q.v.), who in 1798 established a Pneumatic Institute at Clifton, and took him as his assistant. Here he made the acquaintance of the Earl of Durham, of Coleridge, and Southey, and carried on a course of experiments on the respiration of different gases, in which he had more than once nearly sacrificed his life. He thus discovered the singular exhilarating effect of nitrous oxide when breathed. The account which he published in his *Researches Chemical and Philosophical* (1799), although afterwards regretted, established his reputation, and led to his appointment, at the age of twenty-two, as lecturer to the Royal Institution of London. He delivered his first lecture in 1801; and his eloquence, and the novelty and variety of his experiments, soon attracted crowded and brilliant audiences. In 1803 he began researches connected with agriculture, on which he delivered a course of epoch-making lectures, which were published under the title of *Elements of Agricultural Chemistry* (1813). The discoveries, however, on which Davy's fame as a chemist chiefly rests, took their origin in the views which he developed in 1806, in his Bakerian lecture, *On Some Chemical Agencies of Electricity*. This essay was universally regarded as one of the most valuable contributions ever made to chemical science, and obtained the prize of the French Institute. Following out his principle, he was led to the grand discovery that the alkalis and earths are compound substances formed by oxygen united with metallic bases. It was potash that he first suc-

ceeded in decomposing, on the 19th October 1807. When he first saw the globules of the new metal, *potassium*, his delight is said to have been so ecstatic that it required some time for him to compose himself to continue the experiment. He next decomposed soda and the alkaline earths, baryta, strontia, lime, and magnesia; and discovered the new metals, *sodium*, *barium*, *strontium*, *calcium*, and *magnesium*. With regard to the earths proper, he succeeded in proving that they consist of metals united to oxygen. It was reserved for Wöhler and others to exhibit the metals by themselves. He lectured in Dublin in 1808-9, and received the honorary degree of LL.D. from Trinity College.

On 8th April 1812 Davy was knighted; he married Mrs Apreece, a lady of considerable wealth, daughter and heiress of Charles Kerr of Kelso, and resigned the chemical chair of the Royal Institution, April 1813. In order to mark the high sense of his merits, he was elected honorary professor of Chemistry. He discovered the talents of Faraday (q.v.), for whom he secured the appointment as assistant in the laboratory of the Royal Institution. That he might investigate his new theory of volcanic action, he received permission from the French government—though the two countries were then at war—to visit the Continent, and was received with the greatest distinction by the scientific men of France. He was accompanied by Faraday. On returning to England in 1815, he entered on the investigation of the nature of fire-damp, which is the cause of explosions in coal-mines. This resulted in the invention of the Safety-lamp (q.v.). A public subscription of about £1500 was collected as a testimonial by those interested in 1817, and he was entertained to dinner, and presented with a service of plate. He was created a baronet, 20th October 1818. On the death of Sir Joseph Banks in 1820, Sir Humphry Davy was elected President of the Royal Society. In 1820-23 his researches on electro-magnetism were communicated to the Society. He invented an ingenious plan for preventing the corrosion of the copper-sheathing of ships by altering the electric condition of the copper by means of bands of zinc; but the bottoms of the vessels became so foul from the adhesion of weeds and shells that the plan had to be abandoned.

Early in 1825 Sir Humphry Davy had begun to complain of the loss of strength, and in 1826 he had an apoplectic attack. He made two journeys to the Continent for the recovery of his health, and died at Geneva on the 29th May 1829, at the early age of fifty-one. The Genevan government evinced their respect by a public funeral. He was a member of almost all the scientific institutions in the world. Cuvier, in his *Eloge*, says: 'Davy, not yet fifty-two years of age, occupied, in the opinion of all that could judge of such labours, the first rank among the chemists of this or of any other age.' Another critic has said: 'He was not only one of the greatest, but one of the most benevolent and amiable of men.' His widow placed a tablet to his memory in Westminster Abbey, and a statue was erected to him in Penzance. Besides the works already mentioned, and a great number of contributions to the *Philosophical Transactions*, Sir Humphry Davy was author of *Elements of Chemical Philosophy* (1812); *On the Safety-lamp in Coal-mines* (1818); *Salmonia, or Days of Fly-fishing* (1828); and *Consolations in Travel* (1830)—all included in his *Collected Works* (9 vols. 1839-40). See *Memoirs of the Life of Sir Humphry Davy*, by his brother, John Davy (1836); his *Fragmentary Remains* (1858); and *The Life of Sir Humphry Davy*, by Dr Paris (1831).

Davy, John, musician, was born near Exeter in 1763, and died in London in 1824. Many of his songs were great favourites, and though most are

forgotten, 'The Bay of Biscay' has never lost popular favour.

Davy Jones, a sailor's familiar name for a malignant sea-spirit or the devil generally. The common phrase 'Davy Jones's locker' is applied to the ocean as the grave of men drowned at sea. A dubious explanation of the name makes it compounded from *Duffy*, a West Indian negro spirit name, and the scriptural prophet Jonah, in jocular allusion to his somewhat unusual adventures.

Davy Lamp. See SAFETY-LAMP.

Dawalla (*Hypophthalmus dawalla*), a fish of the family Siluridae, found in the rivers of Guiana, and highly esteemed for the delicacy of its flesh. It is sometimes 2½ feet long, and is brightly coloured. The eye is situated below the angle of the mouth.

Dawkins, WILLIAM BOYD, was born at Buttington vicarage, near Welshpool, Montgomeryshire, 26th December 1838, and educated at Rossall School and Jesus College, Oxford. In 1862 he joined the Geological Survey, became curator of Manchester Museum in 1869, and professor of Geology in Owens College there in 1874. In 1882 he presided over the anthropological section at the Southampton meeting of the British Association, and in the same year was elected honorary fellow of his old college. The Channel Tunnel committee employed him in 1882 to make a special survey of both coasts; and next year he laid down the line for a tunnel under the Humber. Professor Dawkins is a fellow of the Royal and other learned societies, and has contributed numerous papers to their issues relating especially to fossil mammalia. His books are *Cave-hunting: Researches on the Evidence of Caves respecting the Early Inhabitants of Europe* (1874), and *Early Man in Britain, and his place in the Tertiary Period* (1880), the latter a work of great interest.

Dawlish, a pleasant watering-place, on the SE. coast of Devonshire, 12 miles S. by E. of Exeter by rail. Backed by the Great Haldon (818 feet), it has public baths, and a dressing pavilion connected with the sea by a small tram-car. Pop. (1861) 3505; (1881) 3977.

Dawn. See TWILIGHT.

Dawson, GEORGE, a busy and popular preacher and lecturer, was born in London, 24th February 1821, taught for a time in his father's academy, and studied at Aberdeen and Glasgow. He became pastor of Rickmansworth Baptist Chapel in 1843; of Mount Zion, Birmingham, in 1844, where his eloquence, breadth of view, and entire freedom from conventionality drew crowds to his services. Dawson's doctrinal position, which did not allow of his being fettered by theological forms of belief, led to his resignation; the 'Church of the Saviour' was built for him (1847), which borrowed its ritual from many sources. He took a lively interest in politics; was extremely popular as a lecturer for thirty years; popularised the views of Carlyle and Emerson, with both of whom he was personally acquainted; taught English literature classes at the Midland Institute for six years; advocated free libraries, and was one of the founders of the Shakespeare Memorial Library, Birmingham. Since his sudden death at King's Norton, near Birmingham, 30th November 1876, other works have been published: *Sermons* (4 vols. 1878-82), *Prayers* (2 vols. 1878-83), *Biographical Lectures* (2 vols. 1886-87), and *Every Day Counsels* (1888). See the Memoir by Crosskey (1876).

Dawson, SIR JOHN WILLIAM, geologist and naturalist, was born at Pictou, Nova Scotia, October 1820. He studied at Edinburgh, and afterwards devoted himself to researches in the

natural history and geology of Nova Scotia and New Brunswick, aiding Sir Charles Lyell in his investigations in Nova Scotia in 1842 and again in 1852. He was appointed superintendent of education in Nova Scotia in 1850; principal of McGill University, Montreal (1855), and afterwards vice-chancellor. In 1882 he received the Lyell medal of the London Geological Society, to whose Proceedings he has frequently contributed; in 1884 he was knighted; and he is an LL.D. of Edinburgh, as well as honorary member of many learned societies. His address as President of the Birmingham meeting of the British Association (1885) was on the geographical history of the Atlantic Ocean. His *Devonian and Carboniferous Flora of Eastern North America* records the discovery of what he believed to be the lowest known form of animal life, the Eozoön Canadense of the Laurentian limestone (see EZOÖN). In some of his works he has combated the Darwinian theory of the origin of species. He has published *Archæia* (1858), *Story of the Earth and Man* (1872), *Dawn of Life* (1875), *Origin of the World* (1877), *Fossil Men and their Modern Representatives* (1878), *Change of Life in Geological Time* (1880), *Egypt and Syria* (1885), and *Science in Bible Lands* (1888).

Dax, a town in the French department of Landes, on the Adour, 93 miles S. by W. of Bordeaux by rail. A fine bridge connects it with its suburb of Sablar; and it has a 14th-century castle, now a barrack, remains of Roman walls, a cathedral and several other interesting churches. It has manufactures of pottery and liqueurs, and some trade; but it is chiefly remarkable for its hot sulphur-springs (77°-144° F.) whose waters are used in cases of rheumatism and nervous complaints. A commodious bathing establishment has been constructed. The springs were known to the Romans, who called the place *Aquæ Tarbellæ*; in the middle ages it was called Aqqs. Pop. (1872) 8154; (1886) 9458.

Day originally meant the space of time during which it is light, in opposition to the space of darkness or night; it now more usually denotes a complete alternation of light and darkness. It is the earth's rotation that causes the vicissitude of day and night. The earth being a globe, only one-half of it can be lighted up by the sun at once; to that half it is day, while to the other half, which is in shade, it is night. But by the earth's rotation, the several portions of the surface have each their turn of light and of darkness. This happens because the position of the earth is such that the equator is on the whole presented towards the sun; had either pole been towards the sun, that hemisphere would have revolved in continual light, the other in continual darkness.

One complete rotation of the earth does not make a day, in the usual sense. If the time is noted when a particular fixed star is exactly south or on the meridian, when the same star comes again to the meridian the next day, the earth has made exactly one rotation, and the time that has elapsed is called a *sidereal day*. This portion of time may be regarded as being always of the same length; for the motion of the earth on its axis differs extremely little from absolute uniformity. Hence sidereal or star-time is much used by astronomers. But the passage of a star across the meridian is not a conspicuous enough event for regulating the movements of men in general. It is not a complete rotation of the earth, but a complete alternation of light and darkness that constitutes their day. This, which is called the *civil* or the *solar* day, is measured between two meridian passages of the sun, and is about four minutes longer than the sidereal day. The cause of the greater length is

this: When the earth has made one complete turn, so as to bring the meridian of the place to the same position among the fixed stars as when it was noon the day before, the sun has in the meantime (apparently) moved eastward nearly one degree among the stars, and it takes the earth about four minutes more to move round so as to overtake him. If this eastward motion of the sun were uniform, the length of the solar day would be as simple and as easily determined as that of the sidereal. But the ecliptic or great circle in which the sun apparently moves, crosses the earth's equator, and is therefore more oblique to the direction of the earth's motion at one time than another; and besides, as the earth moves in her orbit with varying speed, the rate of the sun's apparent motion in the ecliptic must also vary. The consequence is, that the length of the solar day is constantly fluctuating; and to get a fixed measure of solar time, astronomers have to imagine a sun moving uniformly in the celestial equator, and completing its circuit in the same time as the real sun. The time marked by this imaginary sun is called *mean solar time*; when the imaginary sun is on the meridian, it is *mean noon*; when the real sun is on the meridian, it is *apparent noon*. It is obvious that a sun-dial must show apparent time, while clocks and watches keep mean time. Only four times in the year do these two coincide. The difference is called the *equation of time*, because, when added to or subtracted from apparent time, according as the sun comes too soon or too late on the meridian, it makes it equal to mean time. The mean solar day is divided into twenty-four hours, the hours into minutes and seconds. A sidereal day, we have seen, is shorter; its exact length is 23 hours, 56 minutes, 4 seconds of mean solar or common time. Astronomers divide the sidereal day also into twenty-four hours, which are of course shorter than common hours. In the course of a civil year of 365 days, the earth turns on its axis 366 times, or there are 366 sidereal days. Astronomers reckon the day as beginning at noon, and count the hours from 1 to 24. The civil day begins at midnight, and the hours are counted in two divisions of twelve each. The ecclesiastical day was reckoned from sunset to sunset. The Greeks counted their day from sunset, as did also the Hebrews, the Romans from midnight, the Babylonians from sunrise, the Umbrians from mid-day.

The diagram will explain the variation in the relative duration of light and darkness at different times of the year and different parts of the earth's

surface. C represents the position of the earth, P being the north pole of the heavens. E and W represent the east and west points. EQW and EKW are the celestial equator and the ecliptic respectively. Let us suppose the observer to be in the northern hemisphere and that HEH'W is his horizon. When the sun is on the equator it is obvious that the arcs EQW and EKW are equal—i.e. the sun is as long above the horizon as it is below it. But, if the sun be in the northern half of the ecliptic, its apparent path is a circle parallel to EQW passing through the sun's position; and more of this circle is above the horizon than below it. Similarly we can explain the appearances for other positions of the sun and of the observer.

Day, as opposed to night, varies with the latitude and the season of the year. As we go north from

the equator it *increases* in summer, and *decreases* in winter. At the equator, day is a little more, night a little less than twelve hours; at the poles, day is a little more, night a little less, than six months. For the time of day in different countries, see TIME.

A *day*, in Law, includes the whole twenty-four hours from midnight to midnight. In reckoning periods of time from a certain event, the day on which the event occurred is excluded. On the other hand, if it be required to prove survival for a certain number of days, it will suffice if the person be alive for any portion, however small, of the last day. While an obligation to pay on a certain day would therefore be theoretically discharged by payment before midnight, the law requires that reasonable hours be observed—e.g. if the payment (as a bill) is at a bank or place of business, it must be within business hours.

A *lawful day* is a day on which there is no legal impediment to the execution of a writ—i.e. all days except Sundays and fast-days appointed by government. Criminal warrants, and in Scotland warrants against debtors in *meditatione fuge*, are an exception to this rule, and may be both granted and executed on Sundays and fast-days. By 29 Car. II. chap. 7, all contracts made by persons in their ordinary calling on a Sunday are void. The exceptions to this rule will be explained under LORD'S DAY. In England, Christmas-day and Good-Friday generally stand on the same footing with Sundays and fast-days appointed by royal proclamation; but in Scotland there is no exception made in favour of any of the feast or fast days of the church.

Days of Grace.—The time at which a bill is actually *due* and payable, except in the case of bills payable on demand or at sight, is three days after the time expressed on the face of it, and these three additional days are called days of grace. If the third day of grace fall on a Sunday, Christmas-day, Good-Friday, or a national fast or thanksgiving day, the bill is payable the day before. If it fall on any of the other bank holidays, or if the last day of grace is a Sunday and the second a bank holiday, the bill is payable on the succeeding business day (see BILL). Days of grace have now been abolished in many countries, but there are still three allowed in the United States, and ten in Russia.

Day, JOHN (1522-84), a native of Dunwich, was an early London printer, his most celebrated production being Foxe's *Book of Martyrs*.

Day, JOHN, a dramatist, of whose life hardly anything is known. He is mentioned in Henslowe's *Diary* in 1598 as an active playwright. But few of his earlier works have come down to us save *The Blind Beggar of Bednal Green*. Day collaborated freely with contemporary writers, as Chettle and Dekker. Ben Jonson in his conversations with Drummond of Hawthornden grouped him with some other admirable gentlemen and authors as a rogue and a base fellow. His best works that have reached us are a graceful comedy, *Humour out of Breath*, and *The Parliament of Bees*, a kind of allegorical masque in which all the characters are bees. 'The very air,' says Charles Lamb, 'seems replete with humming and buzzing melodies. Surely bees were never so berhymed before.' An edition of Day's works was privately printed by A. H. Bullen in 1881.

Day, THOMAS, the author of *Sandford and Merton*, was born in London, 22d June 1748, and thirteen months later, by his father's death, became heir to £900 a year. From the Charterhouse he passed to Corpus Christi College, Oxford, where he formed a close friendship with Richard Lovell

Edgeworth (q.v.). In 1765 he entered the Middle Temple, in 1775 was called to the bar, but he never practised. A good, clever eccentric, a disciple of Rousseau, he brought up two children, an orphan blonde and a foundling brunette, one of whom should presently become his wife. That scheme miscarried; and, admitted to the Lichfield coterie, he proposed first to Honora Sneyd, next to her younger sister Elizabeth. She sent him to France to acquire the French graces; as acquired by him, they but moved her to laughter. Finally in 1778 he married an appreciative heiress, Esther Milnes, and spent with her eleven happy years, farming on philanthropic and costly principles in Essex and Surrey, till on 28th September 1789 he was killed by a fall from a colt he was breaking in. His wife died broken-hearted two years afterwards, and both lie in Wargrave churchyard near Henley. Two only of Day's eleven works call for mention—*The Dying Negro* (1773), and the *History of Sandford and Merton* (3 vols. 1783-89). The poem struck the keynote of the anti-slavery movement; the child's book, like its author, is sometimes ridiculous, but always excellent. See Day's Life by Keir (1791) and Blackman (1862); also Miss Thackeray's *Book of Sibyls* (1883).

Day-fly. See EPHEMERA.

Day-lily (*Heimerocallis*), a perennial herbaceous genus of Liliaceæ, so named from the ephemeral duration of its individual flowers, which, however, succeed each other freely upon the peculiar inflorescence (a helicoid cyme). Several species are cultivated in our flower-gardens, especially the fragrant Yellow Day-lily (*H. flava*), a native of

Yellow Day-lily (*Heimerocallis flava*).

warmer Europe, Southern Siberia, and Northern China, and *H. fulva*, from the Levant. Both species, but particularly the latter, have been recommended as sources of green fodder for cattle.

Dayton, capital of Montgomery county, Ohio, the fifth city of the state in point of population and of wealth, is situated on the Great Miami, at the mouth of the Mad River, 60 miles NNE. of Cincinnati by rail. The streets are broad, the private residences generally handsome; the public buildings include a court-house of white marble, a large gaol, a number of schools, and about fifty churches. Standing on the line of the Miami Canal (opened 1829), the city is the terminus of eight railroads, and the water of the Mad River is brought through its streets by an hydraulic canal, supplying abund-

ant water-power. It has numerous and important manufactures, including railroad-cars, cotton, woollen, and iron goods, oil, flour, paper, and machinery. Dayton, it may be noticed, is the headquarters of the Gypsies in the United States. Pop. (1870) 30,473; (1880) 38,678.

D'Azara, FELIX, naturalist, was born in Aragon in 1746, entered the army, and in 1781 was appointed a commissioner for defining the Spanish and Portuguese possessions in South America. He wrote an important *Natural History of the Quadrupeds of Paraguay* (1801; Eng. trans. 1838), and *Voyages dans l'Amérique Méridionale* (4 vols. 1809). He died in Spain in 1811.

D'Azeglio. See AZEGLIO.

Deacon, lit. a 'servant' or 'follower' (and, in that sense, found in classic and also in Hellenistic (Greek), became in ecclesiastical usage the name for an office-bearer in the Christian church. In Acts vi. we read of the appointment of seven men chosen by the laity and ordained by the apostles to attend to the finances of the infant church, and to see that its alms are fairly distributed. The name deacon is not applied to them. They are to be spiritually-minded men; they are solemnly set apart from the rest of the congregation; and almost immediately they are found preaching and baptising (Acts, vi. vii. and viii. 38); and the most distinguished of them, St Stephen, dies as the first Christian martyr. In the epistle to the Philippians they are named along with the bishops, and in the pastoral epistles they are recognised as part of the Christian ministry (1 Tim. iii. 8-13) without any special reference to financial duties. Chrysostom suggested that the appointment in the Acts was of a temporary nature, and distinct from the sacred ministry of the diaconate subsequently instituted; and this view obtained some sanction from the sixth General Council. But a great Anglican antiquary, Bingham (supported in this matter by the Roman Catholics Thomassinus and Petavius), takes the opposite side, and is able to appeal to Justin Martyr, Irenæus, Hilary, Cyprian, and other doctors, to the effect that the seven were truly deacons in the later sense, and were authorised by the apostles to undertake these higher functions. The number seven continued to be adhered to in many churches—e.g. at Rome, until the 11th century, when the number was doubled.

During the 2d and 3d centuries, the duties falling to the deacons had considerably increased; and since as confidential attendants and helpers of the bishops, they had risen into consequence, it became necessary to divide the various functions among an arch-deacon, deacons, and sub-deacons. Deacons might now dispense the bread and wine at the communion, but not consecrate them. They had to receive the offerings and presents for the bishop, to keep the sacred vessels, to chant the introductory formulas of public worship, and to take the oversight of the morals of the congregation; and they were allowed, in many cases, with the leave of the bishop, to preach and baptise, and receive penitents into the communion of the church. At an early period, the offices of arch-deacon and deacon were considered to belong to the higher orders of consecration (*ordines majores*); this was not the case with that of sub-deacon till after the 12th century. At the consecration of a deacon, according to the Roman rite, certain sacred vessels may be handed to him as symbols of his office; but this does not seem to be regarded as essential. In the Greek rite the *flabellum* (a fan for driving away flies from the sacred elements) is given to the deacon. The peculiar robes are the dalmatica and the stole, but the stole (both in East and West) is only placed over the left shoulder.

In Protestant churches the position of deacons varies. Among Presbyterians, the elders have the spiritual oversight of the congregations; while deacons (as in the Free Church of Scotland) and managers in others have the care of the financial affairs. Among Congregationalists, the deacons combine both spiritual and financial duties. The Church of England has retained in the main the older form of ordination. The deacon has only the hands of the bishop laid upon him, and not those of any attendant priests also; he cannot consecrate the elements at holy communion or pronounce the absolution or benediction; and he only preaches by special license from the bishop, and not directly by virtue of his office. For this, as well as for holding any benefice or church-preferment, priest's orders are necessary. The office is now regarded very much as simply one of probation before admission to priest's orders. But in ancient times it was not uncommon for a man to remain a deacon for life. The cardinal deacons at Rome sometimes remain such, especially if much occupied with secular business. Thus the late celebrated Cardinal Antonelli always remained a deacon. Before a person can be appointed deacon in the English Church, he must have reached the age of twenty-three, and he usually remains in this office one year at least.

DEACONESSSES (*ancille, ministræ, viduæ, virgines, episcopæ, presbyteræ*), female ministers or servants of the church or Christian society in the time of the apostles (Rom. xvi. 1). At a later period, they co-operated with the deacons, showed the women their place in the church assemblies, assisted at the baptism of persons of their own sex, instructed those who were about to be baptised as to the answers they should give to the baptismal questions, arranged the *agapæ* or love-feasts, and took care of the sick. In the 3d century it seems to have been also part of their duty to visit all Christian women who were suffering imprisonment, and to be hospitable to such as had come from afar. In very early times they were consecrated to their office by ordination in the same manner as other ecclesiastical or spiritual personages; later, however, they were inducted into their office by prayer without the imposition of hands. Until the 4th century, the deaconesses had to be either maidens or widows who had been only once married, and sixty years of age; but after the Council of Chalcedon the age was fixed at forty. Their assistants were called *sub-deaconesses*. After the 6th century in the Latin Church, and after the 12th century in the Greek Church, the office of deaconess was discontinued; but the former has retained the name. In convents, for example, the nuns who have the care of the altar are called deaconesses. In the Reformed Churches of the Continent there are deaconesses who nurse the sick and tend the poor. The first deaconesses' house at Kaiserwerth on the Rhine, near Düsseldorf, was founded by Pastor Flidner in 1836; and now scattered over the Protestant world there are upwards of sixty similar institutions, with fully 6000 sisters. The Church of Scotland adopted the office of deaconess in 1887-88. The Diocesan Deaconess Institution, London, was established in 1861; but Sisterhoods (q.v.) have struck a much deeper root in the Anglican communion. See Dean Howson's *Diaconate of Women in the Anglican Church* (1886).

Deacon of a Trade, the president, for the time being, of certain incorporations in Scotland, where, prior to the passing of the Burgh Reform Act, 1834, the deacons of trades or crafts represented the trades in the respective town-councils. That act enacted that the deacons shall no longer be recognised as official and constituent members of the town-council, but preserved the power of the crafts to elect deacons and other officers for the

management of their affairs. The deacon-convenor of the trades in Edinburgh and Glasgow is still a member of the town-council. See **DEAN OF GUILD**.

Dead, in *seafaring* language, is very frequently employed as part of a designation or phrase having, in general, a meaning somewhat opposite to that of *active, effective, or real*. The chief of such phrases are the following: *Dead-eyes*, circular, flattish wooden blocks, without sheaves, and having eyes for lanyards, which form a purchase or tackle whereby the shrouds or other fixed rigging are extended or set-up taut; *Dead-flat*, the name for one of the midship-timbers; *Dead-lights*, strong wooden shutters used to close cabin-windows, on the approach of a storm, to protect the glass; *Dead-ropes*, such as do not run in blocks; *Dead-wood* is the term applied to the solid blocks of timber erected upon the keel throughout the sharp portions of a ship's hull at stem and stern, the chief object being to give solidity and strength to the ends of the ship; *Dead-reckoning*, an estimation of a ship's place without celestial observations, made chiefly by the log-book, and liable to error on account of currents, lee-way, fluctuation of wind, &c. To these may be added *Dead-wind*, a seaman's designation for a wind blowing directly against a ship's course.

Other compounds are *Dead-lock*, a position of matters when they have become so complicated that they are at a complete standstill and progress is impossible; *Dead-freight*, the compensation paid to the shipmaster by the merchant who freights a whole ship for the space which he fails to occupy; *Dead language*, one no longer spoken; and *Dead-letter*, a letter undelivered and unclaimed at the Post-office (q.v.). The *Dead-points* of an engine are when the connecting-rod and the crank are in one line (see **CRANK**). The impetus of the fly-wheel is necessary to carry the engine over these points, and if it is allowed to stand at either of them, a start is impossible till the fly-wheel is turned by hand sufficiently to permit of the piston acting on the crank.

Dead, **BOOK OF THE**, the great funerary work of the ancient Egyptians, who themselves entitled it *Per-em-Hru*, 'to go forth from (or by) day.' It is 'a collection of prayers and exorcisms composed at various periods for the benefit of the pilgrim-soul in his journey through Amenti (the Egyptian Hades); and it was in order to provide him with a safe-conduct through the perils of that terrible valley that copies of the work, or portions of it, were buried with the mummy in his tomb.' Such copies, hieroglyphic or hieratic according to the age when they were executed, and made some to order, others for sale, constitute fully one-half of the thousands of extant papyri. They are mostly corrupt and faulty; but as the fruit of ten years' toil, a pure text at last has been published by Edouard Naville in *Das Aegyptische Todtenbuch der XVIII. bis XX. Dynastie* (Berlin, 1886), whose folio supplement contains 212 plates of texts, vignettes, and variants of vignettes. Dr Birch's English translation (*Egypt's Place in Universal History*, vol. v. 1867) is based on Lepsius' imperfect Turin text (1842), as also is Pierret's French translation (1882). See the articles **EGYPT**, **HIEROGLYPHICS**, and **AMENTHES**; chap. ix. of E. A. Wallis Budge's *Dwellers on the Nile* (1885); and a masterly article on M. Naville's work by Miss A. B. Edwards in the *Academy* for 10th September 1887.

Dead Nettle (*Lamium*), a genus of Labiatae. *L. purpureum* and *L. album*, together with (*Gale-*

opsis) the closely allied common British weeds.

White Dead Nettle
(*Lamium album*).

Hemp-nettle, are very common. The commoner species have been somewhat thoroughly naturalised in the long-settled parts of the United States. They are sometimes boiled as pot-herbs in Sweden. The name seems derived from the superficial resemblance to the true or stinging nettles; this is especially marked in *L. album*.

Dead Sea is the usual name, dating from the time of Jerome, for a most remarkable lake in the south-east of Palestine, called in the Old Testament *The Salt Sea*, *Sea of the Plain*, or *East Sea*; by Josephus, *Lacus Asphaltites*; and by the Arabs now, *Bahr-Lit*, 'Sea of Lot.' It is 46 miles long, with a

breadth of from 5 to 9 miles. Its surface, which is lower than that of any water known, is 1292 feet below the level of the Mediterranean. The depth of the greater part, the northern section, is about 1300 feet; but at the southern end the water is only from 3 to 12 feet deep. The shape is that of an elongated oval, interrupted by a promontory which projects into it from the south-east. The Dead Sea is fed by the Jordan from the north, and by many other streams, but has no apparent outlet, its superfluous water being supposed to be entirely carried off by evaporation. Along the eastern and western borders of the Dead Sea there are lines of bold, and in some cases perpendicular, cliffs rising in general to an elevation of 1500 feet on the west, and 2500 feet on the east. These cliffs are chiefly composed of limestone, and are destitute of vegetation save in the ravines traversed by fresh-water streamlets. The north shores of the lake form an extensive and desolate muddy flat, marked by the blackened trunks and branches of trees, strewn about and incrustured with salt. The southern shore is low, level, and marshy, desolate, and dreary. On this shore is the remarkable ridge of rock-salt, 7 miles long and 300 feet high, called *Khashm Usdom* ('Ridge of Sodom'). Lava-beds, pumice-stone, warm springs, sulphur, and volcanic slag prove the presence here of volcanic agencies at some period. The neighbourhood of the Dead Sea is frequently visited by earthquakes, and the lake still occasionally casts up to its surface large masses of asphalt. The basin of the sea and the valley of the Jordan seem both to be due to a great fault or crack in the earth's surface of very ancient date. The long-entertained belief that the exhalations from this lake were fatal is not founded upon fact. Within the thickets of tamarisk and oleander, which here and there may be seen upon its brink, the birds sing sweetly, and they fly over and swim about on its surface. But the salinity of the waters is adverse to life, though some lower organisations are found in them.

The water of the Dead Sea is characterised by the presence of a large quantity of magnesian and soda salts. Its specific gravity ranges from 1172 to 1227 (pure water being 1000). The proportion of saline matter is so great, that whilst sea-water contains only 3.5 per cent. of salts, the water of the Dead Sea contains upwards of 26 per cent., or more than eight times as much as that of the ocean. In all

lakes or collections of water without any outflow, the water acquires an infusion of salt, its feeders constantly bringing in this material, while none can go off by evaporation, even when the shores do not as here abound in salt and nitre. The evaporation is great as the heat is intense, and the sea rather contracts than increases. Rain hardly ever falls; the water is nearly as blue and clear as that of the Mediterranean; and though its taste is horribly salt and fetid, a bath in it is refreshing. Owing to the great specific gravity of the water, it is almost impossible for the bather to sink in it, strive as he may. Several of those who have navigated and explored the sea have fallen victims to a fatal fever. For the story of the 'Cities of the Plain,' see Gen. xix.; but according to Captain Conder, 'it is now generally agreed that the Dead Sea and Jordan were formed by a great fault or crack in the earth's surface long before the creation of man, and that the district presents in our own days much the same aspect as in the days of Abraham. It is vain, therefore, to suppose that the "cities of the plain" were beneath the present sea, although this view was held as early as the time of Josephus' (*Bible Geography*, 1884). See also Ritter's *Geography*, and the works on Palestine by Robinson, Stanley, and Tristram; De Luynes' *Mer Morte* (1874); Lieutenant Lynch's *Report of the United States Dead Sea Expedition* (1852); and Professor Hall's *Survey of Western Palestine* (Palestine Exploration Fund, 1886).

Dead's Part, in Scots law, is that part of a man's movable property which he is entitled to dispose of by testament. If a man dies without leaving widow or children, the dead's part is the whole; if he leave widow but no children, or children but no widow, it is a half; and if he leave both widow and children, it is a third of his movable property. The dead's part, however, may be increased or diminished by special provisions in a marriage-contract, or by wife and children renouncing their legal rights. This dead's part in English law is called the 'dead man's part,' and went formerly to pay for masses for the dead man's soul. Afterwards the administrators applied it to their own use, until finally it was by statute subjected to be distributed among the next of kin.

Deaf and Dumb. Persons who are born deaf, or who lose their hearing at a very early age, are dumb also; hence the compound term *deaf-and-dumb*. But deafness is the primary defect; dumbness is only the consequence of deafness. Children ordinarily hear sounds, and then learn to imitate them—i.e. they learn to repeat what they hear other persons say. It is thus that every one of us has learned to speak. But the deaf child hears nothing; cannot, therefore, imitate, and remains dumb. Persons who lose their hearing later in life are not to be classed among the deaf and dumb. Having learned to speak before their hearing was lost, they can readily communicate with others; and if they are educated, there are still open to them all the stores of knowledge contained in books, from which the juvenile deaf and dumb, ignorant of all written and spoken language, are utterly excluded. It is this latter class alone which is contemplated in our census enumerations, and for which our institutions for the education of the deaf and dumb are designed.

The term 'deaf and dumb' is somewhat unfortunate, as embodying and repeating the error that the affliction is twofold. It affects two organs, certainly, but only, as above described, in the way of cause and effect. The organ of hearing is wanting, but the organs of speech are present; they merely lack the means of exercise. The ear is the guide and directress of the tongue; and when the ear is doomed

to perpetual silence, the tongue is included in the ban; though, if we could by any means give to the ear the faculty of hearing, the tongue would soon learn for itself to fulfil its proper office. To correct the error involved in this apparent misnomer, some authorities use the term *deaf* simply, others speak of the *deaf-dumb* and *deaf-mute*. The latter term is common in America, as in France is its equivalent *Sourds-muets*. In the Holy Scriptures the same original word is translated 'deaf' in some places (as in Mark, vii. 32), and 'dumb' or 'speechless' in others (see Matt. ix. 33, and Luke, i. 22).

This affliction is very much more common than, for a long time, and up to a recent period, it was supposed to be. Happily, however, along with the knowledge of its extensive prevalence, has come the means of alleviating it, by education. It was only when the schools now in existence began their useful work, and caused inquiries to be made, that the actual numbers of the deaf and dumb began to appear. In every place where it was proposed to establish a school—in Paris, London, Liverpool, Manchester, Yorkshire, and in New York—the objection was immediately started that children could not be found in sufficient numbers to require such schools. Their promoters, however, knew better than this, and persisted in their design. They soon had the satisfaction of converting the objectors into their warmest supporters; and the institutions thus established in the localities just named are now the largest, the most useful, and the most prosperous in the world.

The facts thus ascertained, and the calculations based upon them, continued to be the only statistics upon the subject of deaf-dumbness in Great Britain and Ireland until the census of 1851: then, for the first time, the number and ages of the deaf and dumb formed a part of the inquiry.

The following table gives the number of the deaf and dumb enumerated at the four respective decennial censuses, with the proportion they bear to the whole population of the several countries.

1851.			
	Number of Deaf and Dumb.	Total Population.	Proportion.
England and Wales	10,314	17,927,609	1 in 1738
Scotland	2,155	2,888,742	1 " 1340
Ireland	4,747	6,552,385	1 " 1380
Islands of the British Seas ..	84	143,126	1 " 1704
Total	17,300	27,511,862	1 in 1590
1861.			
England and Wales	12,230	20,066,224	1 in 1640
Scotland	2,335	3,062,284	1 " 1311
Ireland	4,930	5,798,967	1 " 1176
Islands of the British Seas ..	87	143,347	1 " 1647
Total	19,588	29,070,832	1 in 1484
1871.			
England and Wales	11,513	22,712,260	1 in 1971
Scotland	2,088	3,360,018	1 " 1609
Ireland	4,467	5,412,877	1 " 1211
Islands of the British Seas ..	77	144,638	1 " 1878
Total	18,150	31,629,293	1 in 1742
1881.			
England and Wales	13,295	25,974,439	1 in 1953
Scotland	2,142	3,735,573	1 " 1744
Ireland	3,903	5,174,386	1 " 1296
Islands of the British Seas ..	88	138,791	1 " 1577
Total	19,518	35,023,630	1 in 1794

The increase of population in 1861 above that of 1851 was $1\frac{1}{2}$ millions, and the number of deaf and dumb had also increased; but although the population in 1871 had increased by $2\frac{1}{2}$ millions above that of 1861, the returns show a large decrease in the proportion of deaf and dumb. A further increase of population in 1881 of $3\frac{1}{2}$ millions still shows a diminution in the proportion of deaf and dumb; there was only a total increase of 1368 deaf and

dumb. We can only attribute this to more extended and improved sanitary measures, advanced knowledge in medical treatment, and more careful nursing of children when suffering from those diseases which so frequently result in deafness.

But while social science is prosecuting its important inquiries into the causes, inevitable and preventable, of deafness, Philanthropy has before her the work of educating these 'children of silence,' to whom the ordinary means of instruction are obviously inapplicable, and for whom, until little more than a century ago, there existed scarcely any available means of education at all. The deaf are spoken of frequently in the writings both of the Old and New Testaments; they are alluded to by the poets, philosophers, and lawgivers of antiquity; yet we have no account of any attempt at educating them until the 15th century; no school existed for them until the middle of the 18th; nor could it be said that education was freely offered, and readily accessible, until within the last fifty or sixty years.

Some isolated attempts had been made before the 18th century, by different men, in different countries, and at long intervals, to give instruction to one or two deaf and dumb persons, and their endeavours were attended with various degrees of success. These several cases excited some attention at the time; but after the wonder at their novelty had subsided they seem to have been almost forgotten, even in the countries where the experiments were made. Bede speaks of a dumb youth being taught by St John of Beverley (q.v.), to repeat after him letters and syllables, and then some words and sentences. The fact was regarded as a miracle, and was classed with others alleged to have been wrought by the same hand. From this time, eight centuries elapsed before any record of an instructed deaf-mute occurs. Rodolphus Agricola, a native of Gröningen, born in 1442, mentions as within his knowledge the fact that a deaf-mute had been taught to write, and to note down his thoughts. Fifty years afterwards, this statement was controverted, and the alleged fact pronounced to be impossible, on the ground that no instruction could be conveyed to the mind of any one who could not hear words addressed to the ear. But the discovery which was to give the key to this long-concealed mystery was now at hand. In 1501 was born, at Pavia, Jerome Cardan (q.v.), a man of great but ill-regulated talents, who, among the numerous speculations to which his restless mind prompted him, certainly discovered the theoretical principle upon which the instruction of the deaf and dumb is founded. He says: 'Writing is associated with speech, and speech with thought; but written characters and ideas may be connected together *without* the intervention of sounds,' and he argues that, on this principle, 'the instruction of the deaf and dumb, though difficult, is *possible*.' All this, which to us is obvious and familiar, was a novel speculation in the 16th century. With us it is a common thing for a man to teach himself to read a language, though he cannot pronounce it. There are, for instance, hundreds of persons who can read French, who do not and cannot speak it. Now it is evident, in this case, that written or printed words do impart ideas independently of sounds, yet this was a discovery which the world owes to Jerome Cardan; and it was for want of seeing this truth, which to us is so familiar, that the education of the deaf and dumb was never attempted, but was considered for so many centuries to be a thing impossible.

It was in Spain that these principles were first put into practice by Pedro Ponce (1520-84), a Benedictine monk, and again, in the following century, by another monk of the same order, Juan Paulo Bonet, who also published a work upon the

subject, which was the first step towards making the education of the deaf and dumb permanent, by recording the experience of one teacher for the instruction of others. This book, published in 1620, was of service to De l'Épée a hundred and forty years later; and it contains, besides much valuable information, a manual alphabet identical in the main with that one-handed alphabet which is now in common use in the schools where the alphabet is used, on the Continent and in America. His own system of teaching, however, like that of every teacher in every country before De l'Épée, was in the main oral. The practicability and adaptability of signs, for conversation rather than teaching, had occurred to several of the earlier teachers, but De l'Épée was the first to adopt them as a distinct medium, and the chief medium, of teaching; and so to establish them as a language. Bonet himself says of the manual and written alphabets that they 'should be associated with speech, by pointing to the letter as written with the finger corresponding with the same letter in the manual alphabet and the articulated sound.' He also describes the positions and movements of the vocal organs necessary in pronunciation, as he himself used them, and as, with little variation, Wallis and Amman used them also in later times, believing themselves to have been the original inventors of the methods they employed. From the time of Bonet there was a general awakening of the attention of intellectual men, not only to the importance of the subject, but to the practicability of instructing the deaf-mute. One of Bonet's pupils was seen by Charles I., when Prince of Wales; and the case is described by Sir Kenelm Digby, who met the prince in Madrid, during his memorable matrimonial journey to Spain (1623). Of this pupil, a younger brother of the Constable of Castile, Sir Kenelm gives an interesting account in his *Treatise of Bodies*, how he 'would repeat after anybody any hard word whatever'—not Spanish merely, but English, and even Welsh.

When the art died away in Spain, it was taken up by Englishmen, and began forthwith to assume an entirely new aspect. Dr John Bulwer published, in 1648, his *Philocophus, or the Deaf and Dumb Man's Friend*, in which he speaks of a 'lip-grammar, which may enable you to hear with your eye, and thence learn to speak with your tongue.' Bonet also found in the course of his experience that lip-reading reached a much greater utility than he had, at the outset, thought it capable of. It has been described as the backbone of the oral system. It is the conviction arising from experience, which has in our own days, and in nearly every country, in Italy and France especially, made some of the most eminent sign-teachers the chief advocates of the oral system. Dr William Holder published his *Elements of Speech, with an Appendix concerning Persons Deaf and Dumb*, in 1669; and Dr John Wallis, Savilian Professor of Mathematics in the university of Oxford, both taught the deaf and dumb with great success, and wrote copiously upon the subject. In 1662 one of the most proficient of his pupils was exhibited before the Royal Society, and in the presence of the king. The *Philosophical Transactions* of 1670 contain a description of his mode of instruction, which was destined to bear ample fruits long after his death.

Before the close of the 17th century many works of considerable merit appeared, the chief of which are the *Surdus Loquens* (1692) of John Conrad Amman, a physician of Haarlem; and the *Didascalocophus, or Deaf and Dumb Man's Tutor*, of George Dalgarno (q.v.). This treatise, published in 1680, and reprinted in 1834 by the Maitland Club, is eminently sound and practical, which is the more remarkable, as the author speaks

of it as being, for aught he knows, the first that had been written on the subject. He is the first English writer who gives a manual alphabet. The one described by him, and of which he was the inventor, is, most probably, the one from which the present two-handed alphabet is derived. Henry Baker (q.v.) about 1720 introduced an improved system of his own; in 1765 the Abbé de l'Épée established his little school in Paris; and five years previously, the first school in the British dominions had been started in Edinburgh by Thomas Braidwood (q.v.). He commenced with one pupil, the son of a merchant in Leith, who had strongly urged him to carry into effect the plan of instruction followed by Dr Wallis, and described in the *Philosophical Transactions* ninety years before. His school, the parent and model of the earlier British institutions, was visited and spoken of by many of the influential men of that day, and its history and associations are imperishable. Its local name of 'Dumbiedykes' suggested to Sir Walter Scott a designation for one of his most popular characters in the *Heart of Midlothian*. A visit paid to it in 1773, by Dr Johnson, and his biographer Boswell, supplies one of the most suggestive and characteristic passages in the *Journey to the Western Islands*, in which he speaks of Henry Baker and his unpublished work. In 1783 Braidwood removed to Hackney, near London, and the presence of his establishment so near to the metropolis undoubtedly led to the foundation of the London Asylum in 1792. Dr Watson, its first principal, was a nephew, and had been an assistant, of Braidwood; and he states that, some ten or fifteen years previously, the necessity for the establishment of a public institution had been plainly seen, and some few but insufficient steps taken towards the accomplishment of such a design. From its foundation in 1792 until 1829, it was directed with great ability by Dr Joseph Watson, author of *Instruction of the Deaf and Dumb*.

The numbers of deaf and dumb children at school in the United Kingdom, at the dates given, were as follows:

	1851.	1861.	1871.	1881.	1885.
England and Wales...	816	1001	1200	1782	1991
Scotland	250	240	301	386	412
Ireland	234	399	478	545	555
Total	1300	1640	1979	2713	2958

The above numbers for 1885 do not include the pupils in private schools, but they do include 313 in the special classes for the deaf of the School Board for London, and 128 in those of the School Boards of Sheffield, Leeds, Nottingham, Leicester, Bradford, Greenock, and Dundee.

In England and Wales, in 1885, there were 25 public institutions for the deaf and dumb, and several private ones. The oldest is that of Old Kent Road, London, founded in 1792, and now removed to Margate; the next, that at Edgbaston, Birmingham, 1812. In Scotland there were 8, the one in Edinburgh dating from 1810; in Ireland 4, one in Dublin having been founded in 1816. Altogether it was estimated that there were in the United Kingdom, in 1885, about 48 schools and classes, employing 236 teachers, and containing about 3000 pupils. In the United States there were 61 schools, with 7411 pupils and 596 teachers; in Germany, 96 schools, with 5892 pupils under 595 teachers; in France, 70 schools, 3655 scholars, and 364 teachers; in Italy, 35 schools, 1500 pupils, and 238 teachers. If to these we add the schools in Austria, 18; Switzerland, 15; Sweden, 17; Norway, 8; Russia, 11; Belgium, 11; Spain, 7; Holland, 3; Canada, 7; Australia, 3; with others in New Zealand and Cape Colony, and one at Bombay (the only one in Asia), it will be evident that the schools throughout the world must be about 500 in number.

It is to the 19th century that the honourable distinction belongs of having done so much for the deaf and dumb. This has not been by inventing the art of teaching, or by raising up the earliest labourers in this field of usefulness, but by founding and supporting public institutions for this purpose. De l'Épée, when he opened his school in 1765, had no foreknowledge of the work he was commencing. As his labours increased, he invited others to his assistance, and they were thus enabled to carry the light of instruction elsewhere, and to keep it alive when he was no more. His death took place in 1789, and his assistant, Sicard, succeeded him. Four years afterwards, the school was taken over by the French government, and now exists as the Institution Nationale of Paris. A pupil of this institution, M. Laurent Clerc, went in 1816 to the United States with Mr Thomas Hopkins Gallaudet (1787-1851), the founder and first principal of the American asylum, who in the New World became, like De l'Épée, 'the father of the deaf and dumb.'

There is some diversity of opinion as to which is the best kind of school for the deaf—the boarding or the day school. And with this question is involved, to some extent, the question of systems of instruction. Until the introduction of the oral system from Rotterdam in 1867, and the establishment in 1874 of the classes for the deaf in the ordinary schools by the School Board for London, all the institutions in Great Britain were boarding-schools. Of the two systems—by congregation or by separation—the former, the boarding-school system, is upheld by its advocates for its advantages of continuous teaching, influence, and discipline. These they hold to be of special necessity for the deaf, and not to be attainable, generally, under the day-school system. The latter system is accepted by some, but only as a necessity—not the best to be hoped for, but the best which can be got. Others defend separation, and oppose congregation altogether, on the ground that with the oral system it is the best, absolutely; that the pupils, being taught to *speak* in order to prepare them for the world, ought to live in the world, and so to bring into constant exercise and practice what they have been taught. Living at home or boarding out in families is therefore advocated and adopted, on this ground, in London and in various large towns on the Continent, though in many places where the oral system finds its strongest supporters the boarding-school is still retained. The possible danger to life and limb in passing through crowded streets alone, has combined with other reasons to produce in London the establishment of homes for deaf children—where they are boarded, lodged, and cared for, and receive their education in a conveniently adjacent school-board class. These homes, now occupying seven separate houses, were established by the Rev. Dr William Stainer. They are largely made use of by Boards of Guardians and others, and are called by the founder's name.

The mental condition of the deaf and dumb is so peculiar—so entirely unlike that of any other branch of the human family—that it is extremely difficult, without very close thought, to obtain an accurate conception of it. While almost every one will readily admit that there is a wide difference between a deaf and a hearing child, very few, who have not had their attention specially drawn to the subject, possess any adequate notion of the difference, or could tell wherein it consists. Sometimes the deaf are compared with the blind, though there exists no proper ground of comparison between them. Except that the blind are more *dependent* than the deaf and dumb, the relative disadvantages of the two classes do not admit of a moment's comparison. The blind can be talked with and read to, and are thus placed in direct intercourse with

the world around them: domestic converse, literary pleasures, political excitement, intellectual research, are all within their reach. The born-deaf are utterly excluded from every one of these. The two afflictions are so essentially dissimilar, that they can only be considered and spoken of together by way of contrast. Each of them affects both the physical and the mental constitution; but blindness, which is a greater physical affliction, falls less severely on the mind; while the effect of deafness is the extreme reverse of this—it touches only one bodily organ, and that not visibly, but the calamity which befalls the mind is one of the most desperate in 'the catalogue of human woes.' The deprivation under which the born-deaf labour is not merely, or so much, the exclusion of sound, as it is the complete exclusion of all that information and instruction which are conveyed to our minds, and all the ideas which are suggested to them, by means of sound; as it is through sound alone, in the first instance, that we all learn language, the medium of all knowledge. The deaf know almost nothing, because they hear nothing. We, who do hear, acquire knowledge through the medium of language—through the sounds we hear, and the words we read—every hour. But as regards the congenitally deaf, speech tells them nothing, because they cannot hear; and books teach them nothing, because they cannot read; so that their original condition is far worse than that of persons who 'can neither read nor write' (one of our most common expressions for extreme ignorance); it is that of persons who can neither read, nor write, nor hear, nor speak; who cannot ask you for information when they want it, and could not understand you if you wished to give it to them. *Your* difficulty is to understand *their* difficulty; and the difficulty which first meets the teacher is, how to simplify and dilute his instructions down to their capacity for receiving them.

A class thus cut off from all communication through the ear, can only be addressed through the eye (1) by means of objects, or representations of them, or by the *visible* language of pictures, signs, and gestures; (2) the finger-alphabet (or Dactylology) and writing, which make them acquainted with our own *written* language; or (3) articulation and reading on the lips, which introduce them to the use of *spoken* language. The education of the deaf and dumb must be twofold—you must awaken and inform their minds by giving them ideas and knowledge, and you must cultivate them by means of language. Where the oral system is employed, the deaf child is taught by spoken language as other children are. Where the combined system is in use, a knowledge of things is conveyed by the use of signs; but to this must be added a knowledge of words. These pupils are therefore taught, from the first, that words convey the same ideas to our minds as pictures and signs do to theirs; they are therefore required to change signs for words until the written or printed character is as readily understood as the picture or the sign. This, of course, is a long process, as it has to be repeated with every word. Names of visible objects (nouns), of visible qualities (adjectives), and of visible actions (verbs), are gradually taught, and are readily acquired; but the syntax of language, abstract and metaphorical terms, a copious diction, idiomatic phraseology, the nice distinctions between words called synonymous, and those which are identical in form but of different signification—these are far more difficult of attainment; they can only be mastered through indomitable perseverance and application on the part of the pupil, in addition to the utmost skill and ingenuity of the teacher. The wonder, therefore, surely is, seeing the point of starting, that this degree of advance-

ment is ever reached at all on the sign system; though oral teachers maintain that on their system it is attained readily, in a manner similar to that of hearing children.

Yet it has been set forth by otherwise respectable authority, that the deaf and dumb are a '*gifted race*;' that they are remarkable for 'their promptitude in defining abstract terms;' and those who ought to have known better have strengthened this delusion by putting forth, as the *bond-fide* answers of deaf-mutes, those brilliant aphorisms and definitions of Massieu and Clerc, which are so often quoted at public meetings by eloquent speakers who know nothing of the subject. It is very well known to those who are acquainted with the subject, that the so-called definitions of *Hope*, *Gratitude*, *Time*, *Eternity*, &c., were not Massieu's at all, but those of his master, the Abbé Sicard. The influence of these fallacies has been most mischievous; they raise expectation to a height which is unreasonable, for it is thought that what was done by 'the celebrated pupil of the Abbé Sicard' may be done every day; and disappointment is the inevitable consequence. The honest, laborious teacher who cannot produce these marvellous results, and will not stoop to deception, has often to labour on without that appreciation and encouragement which are so eminently his due; the cause of deaf-mute instruction suffers; and a young institution is sometimes crippled by the failure of support, which was first given from one impulse, and is now withdrawn from another—not a whit more unreasonable than the first, but very unfortunate in its consequences.

In 1886 the education of the deaf and dumb was referred to the investigation of a Royal Commission which has instituted far-reaching inquiries, from which valuable results are anxiously expected. But the most striking feature of all has been the rapid diffusion of the pure oral system. Originally confined to Germany and Holland, it has since 1867 spread over western Europe and America, sometimes forming by itself the sole principle of instruction, and sometimes, though against the views and protests of its principal advocates, in combination under the same roof with the *sign* or *manual* system. It was introduced into London in 1867, at the instance of the late Baroness Meyer de Rothschild, and applied by Mr Van Praagh, at the Jews' Deaf and Dumb Home. In 1871 it was extended by the establishment of the 'Oral Association,' whose school and training college, placed under the direction of Mr Van Praagh, are in Fitzroy Square. In 1877, by the efforts and influence of Mr B. St John Ackers, the training college and school was founded which has its headquarters at Ealing, and of which one of the chief objects was the diffusion of the 'German' system in the United Kingdom. The college of teachers was established later, in 1885. It has had a successful career. Nearly every head-master in the kingdom is a member, and it has attracted a large number of the younger teachers to its examinations, all of whom are required to pass in subjects set by the heads of the profession, including the ability to teach on the oral system. This method, advocated by the means already named, had been prosecuted with great zeal and much success, but was wonderfully accelerated by the international congress held at Milan in September 1880. Here the pure oral system was stamped with almost unanimous approval, and its acceptance, either wholly or partially, speedily followed in every country in Europe and some more distant regions. It was at once adopted in the three national institutions of France—the birth-place and cradle of the sign or French system; and by 1884 more than 60 per cent. of all the known schools in the world had proclaimed their full

adoption of it. In Germany, Austria, Hungary, Luxemburg, the Netherlands, and Switzerland its adoption was universal; in Italy it prevailed in 34 out of 35 schools; and in Norway in 6 out of 7. In other words, it was the system in actual practice in all the schools of some countries, in nearly all of other countries, and in a continually increasing number in every country where the deaf are taught at all.

The oral system, discarding signs and the manual alphabet as instruments of teaching and as means of communication, employs speech and lip-reading for these purposes. The child is taught (a) to speak by seeing how his teacher speaks; (b) to lip-read—that is, to read the speech of his teacher and others as expressed upon their lips; and to understand so much of this as is co-extensive with his own knowledge of language, to which he is of course adding daily and hourly by means of speech. Instruction comes to him by the spoken and written language of the hearing, not by the signs and gestures of the deaf. Thus, he speaks, he lip-reads, and he has books opened to him. The first attainment, striking as it is, is as nothing to the second, and the second is inferior to the third. It cannot be too clearly understood that the greatest and most certain of all these advantages is the last-named. The acquirement of speech may be more or less perfect, therefore more or less uncertain as a means of communication; but the ability to read the lips of other persons does not depend on this, and it is much the more valuable of the two, because by this means the mind which is full is laid open for the information of the mind comparatively empty. But the ultimate attainment—the command of books and literature afforded by the mastery of language—is, in regard to intellectual cultivation and moral guidance, incomparably the most valuable acquirement of all, however gained. Nothing is to be compared with this as a means of breaking down the barrier and bridging over the gulf which separates the deaf from the hearing—the most formidable and at first sight the most impassable which can separate man from man. By way of illustration, it has been said that the mental condition of the born-deaf, without education, is blank imprisonment in the most awful solitude; that the sign system removes this to the extent of enabling the captives to associate with each other; while the pure oral system throws open the doors of their captivity, and sends them out to take their part in the life and action of the world around them.

The modes of teaching on the oral system are not everywhere uniform, though the principles are the same. These methods vary to some extent in different countries, being influenced by the character of the language, and are essentially traditional. Some eminent authorities teach the vowels first, others the consonants; the simple combinations follow, afterwards those which are less simple, and then short phonetic words, leading on to simple sentences. The vocal organs are trained to pronounce and the eye to observe (i.e. to lip-read) simultaneously. It is gravely erroneous to suppose that teaching speech is all that is meant by teaching on the oral system. Its advocates say that, with pupils properly taught, lip-reading, articulation, and writing are simultaneous. One branch is not allowed to get ahead of the other. To acquire a new word, the pupil first reads it from his teacher's lips; he is next taught to pronounce it himself, and then to write it down. On this principle the whole course of instruction is carried out. The system, to be successful, demands its own conditions, of which a longer school term (eight years at least), an earlier commencement (at the age of seven or younger), smaller classes (of not

more than eight or ten), teachers trained specially to the work, and the exclusion of signs and the manual alphabet are held to be indispensable. The growth and decadence of the sign system is historic. It came in after 1760. It then took hold and grew, and maintained its ascendancy for nearly a hundred years, when the reaction began which has marked our own times. Before 1760 there were no public schools; all teaching was individual and private, and it was oral. After 1765, when De l'Epée had a school of sixty children and no assistants, it is no wonder that he gave his preference to signs, whereby the pupils could help to teach each other, and he could address them all at once. So speech was abandoned, except in some favourable cases as an accomplishment; signs became the language of deaf-mutes, teachers were few and inadequate, a large proportion of them

Two-handed Alphabet.

were deaf themselves, teaching deteriorated, and interest languished. Meanwhile, the best men did the best that was possible with an imperfect instrument. The sign system was such an instrument, and what was within its capabilities they did devotedly and did well. But with the superior instrument, the oral system, applied with the same energy and zeal, higher results have been reached, notably, in many instances, by the same men.

Though they have worked on each method as it came before them, there never was in the minds of the most experienced teachers any doubt as to the superiority of speech over signs. The question was never, which system is the best? but which system is the most practicable in large schools? It is obviously better that deaf persons should use the speech common to everybody than the language of nobody but themselves. Until seventeen hundred people go out of their way to learn the language of one, the deaf minority must stand isolated in the world, shut up with each other. Though such as have learned to speak may not, with all their

efforts, succeed in rising to the level of those that hear, yet the efforts made are themselves improving, and habitual practice is still more so; whereas the practice of signing is distinctly lowering and hindering. Those taught by signs think in signs; those taught by speech think in words. The mixture of the two is injurious; translation from signs to words produces confusion; signs invert language, and when the two systems are placed together signs become the dominant power, and speech the lesser one; then comes in a combined system in which the oral system stands degraded, of which it has been said, to degrade it is to kill it. Natural signs—the signs which all hearing persons understand—are allowed to be used for purposes of explanation, and some authorities permit the use of the manual alphabet as well, because what is conveyed by the manual alphabet is identical with language, and not, like conventional signs, an imperfect substitute for it. But the inflexible advocates of the pure oral system condemn and exclude signs and the manual alphabet altogether. Signs, they say, are at best but a 'baby language,' wedded to which the mind cannot grow, and with which, alone, intellectual maturity can never be attained.

Excellent work for the deaf and dumb has been done in the United States. The institutions there are munificently supported by grants from the states, and are admirably managed. The staff of teachers is numerous, able, and efficient, and a high degree of success is attained where the work is carried on under advantages which are unknown in the schools of Great Britain. At Washington a college was established in 1864, under the presidency of Dr E. M. Gallaudet, the youngest son of the founder of the American Asylum. It is empowered by the United States government to confer degrees, and has expressed this power by conferring the title of Doctor upon four prominent experts in Great Britain—Messrs Charles Baker and D. Buxton in 1870, and R. Elliott and W. Stainer in 1887. The same honour was conferred in 1880 upon Professor A. Graham Bell. The inventor of the telephone, he is also well known by his interest in the education of the deaf on the oral system, of which he is one of the most eminent and influential advocates. That advocacy is mainly based on educational grounds, but also as a check to the evils arising from the congregation of the deaf and dumb together in institutions—their general association with each other, their frequent intermarriages, the consequent excess in the births of deaf-mute children, and the danger, by no means visionary, he insists, of 'the formation of a deaf variety of the human race.' In New York the Rev. Dr Thomas H. Gallaudet, vicar of St Anne's, in 1852 started services in his church in the sign language, and in 1872 organised a mission to promote the temporal and spiritual welfare of adult deaf-mutes in other cities of the Union. In London St Saviour's church was built to meet the same necessity, and religious services have been conducted there by successive chaplains. Another clergyman and several laymen conduct similar services in various parts of the metropolis. In Liverpool, Manchester, Edinburgh, Glasgow, and Dublin, also in Birmingham, and the large manufacturing towns of Yorkshire, special funds are raised, and special agents employed, to promote in like manner the social and religious benefit of the deaf and dumb.

The earlier publications on this subject are mentioned above. Works of more recent date have been chiefly controversial and educational. The contentions between the rival systems have been carried on with much vigour and spirit in numerous articles, reports, and pamphlets; and education has been promoted by the publication of

the lesson-books of several prominent teachers. Of these, it must suffice to mention those of the late Dr Harvey P. Peel of New York, and those of Moritz Hill of Weissenfels. Of the latter work an English translation, with the illustrations, has been brought out by Dr William Stainer. The London College of Teachers has also published a *Manual for Students on the Education of Deaf-mutes*, by the Rev. Thomas Arnold.

DEAF AND DUMB, in Law. The Roman law held deaf and dumb persons to be incapable of consent, and consequently unable to enter into a legal obligation or contract. Both in England and Scotland they may make contracts or wills if they have the use of reason and understand the nature of their undertaking, and express their consent intelligibly. Although the presumption of law is that a deaf and dumb person is in the same state as an idiot, and incapable of any understanding, such a one may be subjected to a criminal trial on proof that he knows right from wrong. And, if he understands the nature of an oath, and is possessed of intelligence, he may give evidence as a witness by signs through an interpreter or by writing. It is always a good objection to a jurymen that he is deaf and dumb.

In the United States, in general, the legal presumption of the common law as to the mental incapacity of the deaf and dumb does not exist. They are presumed to be capable of comprehending the nature of crime, the nature and obligation of an oath, and of making any contract; hence may be indicted, tried, and punished for crime, and may testify as witnesses. The federal courts have no peculiar jurisdiction as to persons deaf and dumb, but the act of congress prescribing punishment to be inflicted upon 'every person' who is guilty of certain acts prohibited, includes every person possessed of sufficient mental capacity for criminal responsibility, although they may be deaf and dumb. The federal courts are governed by the practice of the states in which the cause is pending as to the competency of a deaf and dumb person as a witness, and this competency will be determined in either state or federal court by the judge before whom the cause is pending, upon examination of the individual, and upon testimony of those acquainted with the party. A deaf and dumb person is legally incapacitated to serve as a juror, or for service in the army and navy, but in other respects has the rights of citizenship.

Deafness. See EAR, DISEASES OF.

Deák, FRANCIS, Hungarian politician, was born in 1803 at Kéhid, in the district of Szalad, where, after a course of legal study at Raab, he practised as an advocate, until returned as its representative to the national diet in 1832. Here he soon took his place as leader of the liberal opposition, and by his firm and moderate policy effected reconciliations between Hungary and the Austrian emperor as her king—temporarily in 1840, and more permanently in 1867. After the revolution of March 1848 he became Minister of Justice in the cabinet of Count Batthyányi, and made every effort to ward off the inevitable war. On Kossuth's coming into power (September 1848), Deák resigned his portfolio, and after the unsuccessful attempt next year at negotiation, withdrew from public affairs, and retired to his estate. He refused to return to public life till 1860, when a constitution was granted to his country.

Returned by Pesth to the diet in 1861, he again became the leader of the moderate party, while the extreme party collected round Count Téli. The death of the latter (8th May) destroyed the only influence which could counterbalance that of Deák; and the diet appointed him to draw up the address to the emperor demanding the constitution of 1848,

a Hungarian ministry resident in Pesth, the return, without restriction, of the exiles, and the restitution of their property. The emperor answered it by a hostile rescript, against which Deák protested strongly. Out of the humiliation of Austria in 1866 came the triumph of Deák's policy. He asked nothing more than before, and thus his wise and statesmanlike moderation effected a satisfactory constitutional relation between Austria and Hungary in the dual system of monarchy. Deák's party was all-powerful, but he lived to see the rise of a more advanced party under the leadership of Tisza. He died at Buda-Pesth, January 29, 1876. See Memoir, with preface by Grant-Duff (1880).

Deal, a municipal borough and sea-bathing place, in the east of Kent, on a bold open beach, near the south extremity of the Downs, between North and South Foreland, 89 miles by rail from London, and 6 miles SE. of Sandwich. Till 1885 it was part of the parliamentary borough of Sandwich. A fine anchorage extends 7 or 8 miles between Deal and the Goodwin Sands. Deal has mainly arisen to supply the wants of the numerous vessels which are often detained by the winds in the Downs. The chief branches of industry are connected with maritime pursuits, boat-building, sail-making, piloting or hovelling, victualling and naval stores. The prosperity of the place now largely depends on its sea-bathing, on the military dépôt at Walmer (2 miles S. of Deal), and on the shipping in the Downs. The handsome iron promenade pier was erected in 1864. Pop. (1851) 7067; (1881) 8422. It has been one of the Cinque Ports (q.v.) since the 13th century. Of the three castles built by Henry VIII. in 1539, Deal Castle is the residence of its 'captain'; Sandown Castle (where Colonel Hutchinson died) to the north of Deal, was pulled down in 1864 on account of the inroads of the sea; and, to the south, Walmer Castle is now the official residence of the Warden of the Cinque Ports. By some it is maintained that it was near Deal that Julius Cæsar, with two legions, in eighty-two ships, landed in 55 B.C.—The Deal boatmen are, like some of the other boatmen on that coast, locally known as 'hovellers.' They are noted for giving assistance to ships in distress, and were formerly much employed in carrying off provisions to outward-bound vessels, and in bringing ashore mail-bags requiring to be forwarded by express.

Dealfish (*Trachypterus*), a genus of deep-sea bony fishes, in the Ribbon-fish (q.v.) sub-order of Acanthopteri. As the name suggests, the elongated body is laterally compressed, and with the exception of a small separate anterior portion, the dorsal fin is continuous along the back. The tail fin is peculiar in being turned sharply upwards. The pectoral fins are well developed. The skeleton is very brittle. Some eight species are known, on European coasts and from the west of South America. They rarely come to the surface. One form (*T. arcticus* or *bogmarus*, the vaagmaer of Icelanders and Norwegians) is occasionally found on North British coasts. It is a large fish, 4 to 6 feet in length, and of a silvery colour. The dorsal and caudal fins are red. A smaller species (*T. tania*) occurs along with others in the Mediterranean.

Dean. The word dean, from the Greek *decanus*, properly means an officer over ten subordinates, the etymon being *deka*, 'ten.' It is first found as a military grade, being mentioned by Vegetius in the 4th century as an old but then disused term (*De Re Milit.* ii. 8). Somewhat later it appears, still in the 4th century, as a title of certain minor officers in the imperial household (St Ambrose, *Epist.* i. 20; St Chrysostom, *Hom.* 13, in Heb. vii.). With the rise and organisation of monachism, the name

was given to a monk placed in charge of ten others, for whose discipline or execution of appointed tasks he was responsible (St Augustine, *De Mor. Eccl. Cath.* i. 31); and in the legislation of Justinian the word has yet another sense, being applied to the public officers having superintendence of funerals (*Novell.* 43, 59). In the Visigothic and Anglo-Saxon codes the *decanus* is a judge of first instance or other legal officer having jurisdiction within a tithing, for every hundred consisted of ten districts, called tithings, and in every tithing was a constable or civil dean. The monastic model was adapted to collegiate and other churches having a large staff of clergy, and the dean in such churches presided over ten canons or prebendaries, though this rule of number does not seem to have been strictly required. In conformity with this, the spiritual governors, the bishops, divided each diocese into deaneries or decennaries (Lat. *decem*, 'ten'), corresponding to tithings, each of which was the district of ten parishes or churches, over every one of which a dean was appointed, who in the cities or large towns was called the dean of the city or town, and in the country, *dean of Christianity, or rural dean*. In the English Church there are the following dignitaries who bear this name:

(1) In the province of Canterbury it is part of the dignity of the archbishop to have prelates to be his officers, and of these the Bishop of London is his provincial dean; and when a convocation is assembled, the archbishop sends to him his mandate for summoning the bishops of the province. This is the sole example of the kind.

(2) *Honorary Deans*, as the Dean of the Chapel Royal of St James's. See CHAPEL ROYAL.

(3) *Deans of Peculiarities*, as of Battle in Sussex, founded by William the Conqueror in memory of his conquest. There are also the Deans of the Arches in London, of Bocking in Essex, and of Croydon in Surrey, who have jurisdiction, but no cure of souls.

(4) *Deans of Chapters*, as at Canterbury, St Paul's, &c., who are governors over the canons in cathedrals and collegiate churches. Their appointment is in the direct patronage of the crown, which may appoint by letters-patent; and the dean so appointed is entitled to be installed. The dean of a chapter must reside eight months in the year, and he may hold one benefice with his deanery. The income of the office is, in the case of Durham, £3000; of St Paul's, Westminster, York, and Manchester, £2000; of other cathedrals, £1000, except St Davids and Llandaff, which have £700. See CATHEDRAL.

(5) *Rural Deans*.—This is a very ancient office of the church, but custom gradually transferred its duties to the archdeacon, as in the visitation of churches, parsonage-houses, &c. Rural deans, however, may act as deputies to the bishop and archdeacon; and since 1850 the office has been revived with great advantage, and in well-ordered dioceses affords a useful channel of communication between the bishop and his clergy, and a means of joint action in matters affecting the church. There are altogether nearly six hundred rural deaneries in England and Wales.

In the universities of Oxford and Cambridge the dean is the officer who superintends the discipline of the college and the chapel services. At Christ Church, Oxford, which is a cathedral, the dean is master of the college.

In the Roman Curia the Cardinal-bishop of Ostia is *ex officio* dean of the College of Cardinals; but while the head of foreign collegiate churches is styled dean, the officer bearing that title in cathedral churches is inferior in rank to the provost in some cases, and in others to the vicar-general; and in feudal times the clerks who acted

as deputies for the lay-abbots of impropriated foundations were also styled deans.

Dean, FOREST OF, a picturesque hilly tract, 34 sq. miles in extent, in the west of Gloucestershire, between the Severn and the Wye, and within the hundred of St Briavels, is an ancient royal forest. It was almost entirely disafforested by Charles I., on a sale to Sir John Wintour, but was re-afforested by act of parliament very shortly after the Restoration. The greater part still remains crown property; and about one-half is appropriated for the growth of timber for the navy. It is divided into six 'walks,' which contain woods of oak, beech, &c. There are coal and iron mines, and quarries of stone suitable for building and making grindstones, troughs, and rollers. Persons born in the hundred, and residing and working a year and a day in the mines, become, on registration, free miners. Their ancient privileges, entitling them exclusively to grants of the crown mines (subject to the right of the crown to put on a fifth man for every four miners, now commuted for a royalty), and, formerly, to timber for the mines, were regulated and enforced by the Mine Law Court, held at the Speech House, within Dean Forest, where the Verderer's Court is still held; but have, with some variations, been defined and confirmed by several acts and commissioners' awards of the present century. Dean Forest is under the control of the Commissioners of Woods and Forests, one of whom, as 'gaveller,' has the supervision of the mines, and a deputy-surveyor, deputy-gaveller, registrar, four verderers (whose office, since the extermination of the deer in 1854 is almost a sinecure), and other officials.

Dean of Faculty. See ADVOCATES.

Dean of Guild, in Scotch burghs, was the head of the mercantile body called the Guild-brethren (see GUILD). In former times (Act 1593, chap. 180) he was a judge in mercantile and maritime causes within the burgh, but for a very long period he has been rather what might be called a Scotch kind of *Edile* (q.v.). His chief duty is now to see that buildings within the burgh are erected according to law, and, in case of their falling into a ruinous condition, to order them to be pulled down. Though in some of the larger burghs the dean of guild is still (3 and 4 Will. IV. chap. 76, sect. 22) a member of the town-council *ex officio*, his jurisdiction is altogether separate from that of the bailie-court. In Edinburgh the Dean of Guild Court, in addition to the dean of guild, consists of five members of the town-council, and five registered electors of the city, not being councillors, of whom three must be architects, civil engineers, ordained surveyors, or master-builders. They are assisted by the law assessors of the magistrates of the city. No building can be either erected or demolished, or even materially altered, without a warrant from this court. Ventilation and sanitary arrangements are under the control of this court. Opposition to the granting of the warrant may be offered either by a private party or by the corporation acting for the public interest. The enforcement of the Act 1698, chap. 8, as to the height of buildings, the thickness of the walls, &c., lies within the province of the Dean of Guild Court. The judgments of the Dean of Guild Court may be reviewed by the Court of Session.

Death. It is one of the fundamental doctrines of physiology, that every part of the organism has its own definite term of vitality, and that there is a continuous succession of the destruction of old cells and the formation of new ones in all tissues, and especially in those in which the most active vital changes are going on, as, for example, in the nervous and muscular tissues. Even the most solid portions of the animal frame, such as the

bones and (to a less extent) the teeth are undergoing a perpetual although a slower change of this nature; and throughout the whole body there is a continuous removal of effete or worn-out tissues, and a corresponding deposition of new matter. Every blow we strike, every thought we think, is accompanied by the death and disintegration of a certain amount of muscular or nervous tissue as its necessary condition; and thus every action of our corporeal life, from its beginning to its close, takes place at the expense of the vitality of a certain amount of organised structure. This is termed *molecular death*, and, within its proper limits, is obviously essential to the life and well-being of the organism.

The cessation of the circulation and respiration may be regarded as constituting *somatic death*, or the death of the entire organism, which must obviously be shortly followed by the molecular death of every portion of the body.

We shall now briefly notice the principal modes in which death occurs. Death happens either from the natural decay of the organism, as in old age, or (and much more frequently) from some of those derangements or lesions of the vital organs which occur in the course of the diseases and injuries to which we are liable. These derangements of the vital organs may occasion various modes of dying. Dr Watson said that life rests on a tripod, whose three vital supports are the *heart*, the *brain*, and the *lungs*; and Bichat, that 'the mode of dying may begin at the head, the heart, or the lungs'. The functions of these organs are, however, so mutually dependent upon each other, that impairment in the functions of one of them may lead to death, though the immediate cause of death is the failure of another.

Death from failure of heart may be either sudden or gradual. Sudden failure (death by *syncope* or fainting) may occur from disease or weakness of the heart itself, or from shock conveyed to it through the nerves. Gradual failure takes place when the whole system is enfeebled—e.g. by the action of certain poisons, and by many wasting diseases (death by *asthenia*, Gr., 'want of power'). When death occurs from loss of blood (anæmia), the failure of the heart may be either sudden or gradual, according to the extent of the loss; but in this case the heart ceases to contract not from inability to do so, but because the blood, its natural stimulus, is insufficient in amount to excite contraction.

Death from failure of respiration (Asphyxia, q.v.) occurs when access of the air to the lungs is impeded, or when the actions of the muscles of respiration cease. We have examples of it in drowning, smothering, choking, strangulation, &c. Forcible pressure upon the chest, such as sometimes happens in great crowds, or as occurs to workmen partially buried by the fall of earth, &c., will cause death in a few minutes, if movement of the lungs is prevented by the pressure. Tetanus and the poison of strychnine prove fatal in this way.

Death by coma, or beginning at the brain, is caused by obstruction to the circulation through that organ by pressure (as, for example, when there is effused blood within the cranium, or when a portion of bone is depressed in a fractured skull); by clots of blood within the vessels; by various narcotic poisons, such as opium, alcohol in excessive quantity, carbonic acid, &c.

To these forms of dying some writers propose to add *necræmia*, or death beginning in the blood, as in typhoid fevers and in other diseases of a malignant or pestilential kind. Such cases may, however, always be referred to one of the three forms already enumerated, or a combination of them; and further complication seems unnecessary.

The signs of approaching death require a brief notice. The mind may be affected in various ways; there may be dullness of the senses, vacancy of the intellect, and extinction of the sentiments, as in natural death from old age; or there may be a peculiar delirium, closely resembling dreaming, which usually is of a pleasing and cheerful character.

Dementia or imbecility sometimes comes on shortly before death, and manifests itself by an incapacity of concentrating the ideas upon any one subject, and by an almost total failure of memory. The mental weakness is often exhibited by the pleasure which is derived from puerile amusements. Shakespeare notices 'playing with flowers' as a token of approaching dissolution. In the form of delirium, ocular spectra seem frequently to be present, the patient apparently trying to catch some imaginary object.

There is generally well-marked relaxation and incapacity of the muscular system, and the voice is usually weak and low as death approaches, often dwindling to a mere whisper. The mode in which the action of the heart declines is various; in most diseases of long standing, the cessation of the heart's action is gradual, the rate of the pulsations being much increased, but their energy being very much impaired. In some acute affections, the failure is shown by the irregularity of the pulse, while the force is little altered. In other cases (especially in cerebral diseases) the heart, before finally ceasing to beat, contracts violently, and suddenly stops.

The respiration is sometimes hurried and panting till just before death, while in other cases it is slow, laborious, and stertorous. The accumulation of mucus, &c. in the air-passages increases the difficulty of breathing; the sound known as the 'death-rattle' being produced by the passage of the air from the lungs through the fluid collected in the trachea and upper respiratory passages. There is also a loss of animal heat, beginning at the extremities.

The *signs of actual death* may be arranged under three heads: (1) Signs of the extinction of the vital functions; (2) Changes in the tissues; (3) Changes in the external appearance of the body.

(1) The arrest of the circulation and respiration would at first sight appear to afford decisive evidence of death; but these functions, as in the case of hibernating animals, may be reduced to so low a condition that it is by no means easy to decide whether or not they are completely annihilated. In cases of apparent drowning, and in newly-born infants, these functions are frequently suspended and again restored; and cases like that of Colonel Townsend (see any standard work on medical jurisprudence) occasionally occur, in which the patient has the power of voluntarily suspending these functions for a considerable period. The gradual loss of animal heat is an important sign. But it is sometimes delayed; and in exceptional cases a rise of temperature may even take place after death. Loss of contractility of the muscles when a galvanic current is applied to them is a certain sign of death; but the period at which it takes place is very variable. The contractility of the skin is also lost after death. When a cut is made through the skin of a dead body, the edges of the wound collapse, while a similar lesion inflicted during life presents an open or gaping appearance.

(2) Among the changes in the tissues, the *rigor mortis*, or rigidity of the muscles, which ensues at a varying period after death, is the most important. It may appear within half an hour after death, or may be delayed twenty or thirty hours, according to the nature of the disease; and its mean duration is from twenty-four to thirty-six hours. It commences in the neck and trunk, then appears,

according to most observers, in the upper, and lastly in the lower extremities, and disappears in the same order.

(3) Various changes in the external appearance of the body have been regarded as indicative of death by different writers; of these, the most important unquestionably is the altered colour of the surface. Livid spots of various sizes may occur from local congestions during life; but the appearance of a green tint on the skin of the abdomen, accompanied by a separation of the epidermis, is a certain sign that life is extinct.

The discrimination of true from apparent death is obviously not a matter of mere physiological interest. The case of Vesalius, the eminent anatomist, who opened an apparently dead body in which the exposed heart was seen to be still beating, is well known; as also that of the Abbé Prevost, who, having been struck down by apoplexy, was regarded as dead, but recovered his consciousness under the scalpel, and died immediately afterwards; and a French author, Bruhier, in a work *On the Danger of Premature Interment* (1742-45), collected fifty-four cases of persons buried alive, four of persons dissected while still living, fifty-three of persons who recovered without assistance after they were laid in their coffins, and seventy-two falsely considered dead. But when reasonable care is taken such mistakes are hardly possible. See BURIAL, CATALEPSY.

Death, CIVIL. Death, in a legal point of view, is either natural or civil: the former being the cessation both of physical life and of the legal rights which attach to it; the latter, the cessation of the legal rights whilst the physical life remains. A man was said to be civilly dead in England when he had been attainted of treason or felony, or had abjured the realm, or was banished, or became professed in religion by going into a monastery. In these events his property devolved as if he were naturally dead. The doctrine of civil death is now abolished except as to cases of outlawry, in which it seems still to be applicable.

Death, DANCE OF. See DANCE OF DEATH.

Death, PUNISHMENT OF. See CAPITAL PUNISHMENT and EXECUTION.

Death, REGISTRATION OF. See REGISTRATION.

Death-bed, LAW OF, in Scotland. According to this law, which was peculiar to Scotland, an heir in heritage was entitled to reduce all voluntary deeds granted by his ancestor to his prejudice, if they were granted by this ancestor on his death-bed. It was necessary that at the time the deed was granted the ancestor should be suffering from the disease of which he died, and should not survive for more than sixty days. The law did not apply if, after granting the deed, the ancestor was able to go unsupported to kirk or market. The law of death-bed was abolished in 1871.

Death Duties. See LEGACY.

Death's-head Moth (*Acherontia atropos*), a species of Hawk-moth (q.v.), in the family Sphingidae, not uncommon in some parts of England and of the continent of Europe. It is widely distributed over the world, being found in Africa, the Mauritius, and the East Indies. It is one of the largest of the European Lepidoptera, and measures almost six inches from tip to tip of the extended wings. The general colour is dark, the woolly body yellow, with black markings, the thorax with markings which have some resemblance to a skull, the upper wings mottled with brown, black, and yellow, the hind wings dark yellow with two black bands. The large caterpillar is greenish-yellow, the back speckled with black, with transverse lines partly blue and partly

white. The tail end bears an S-shaped horn. In countries where the potato is cultivated it is often to be found feeding on the leaves of that plant.

Death's-head Moth (*Acherontia atropos*) and Caterpillar.

In the pupa stage it is brown, and lies in a hole in the ground. The insect is nocturnal in habit, and is interesting as an audacious plunderer of bee-hives. How it daunts the bees is a mystery. Even more remarkable is the much discussed shrill piping note, which is probably produced by the forcible expulsion of air from the fore-gut through a cleft in the proboscis. The sudden appearance of large numbers is popularly regarded as ominous of evil, and in the Mauritius the insect is believed to cast from its wings a dust which produces blindness in those persons on whom it falls.

Death-watch, a ticking or rapping noise produced by various insects in houses. Being oftenest heard in the quiet of sickness and anxiety, it has been superstitiously regarded as a signal of approaching death. In Britain it is generally the love-signal of the small boring beetle (*Anobium*, see BORERS), of a brownish colour, and about $\frac{1}{2}$ inch in length. Various species frequent wood, furniture, &c. *A. pertinax*, *A. tessellatum*, and *A. striatum* are all common death-watches. Some other insects besides *Anobium* make tapping noises, notably the Giant Cockroach (q.v.) or drummer. One of the book-lice (*Atropos pulsatorius*), in a very different order, used to be regarded erroneously as the 'death-watch.'

Debauché, a French word, meaning in that language the breaking up of the ice in a harbour or river, but introduced into English by geologists to express any sudden flood of water, which bears before it opposing obstacles, and leaves its path marked with confused and scattered fragments of rocks, stone, and other debris.

De Bary, HEINRICH ANTON, an eminent botanist, born at Frankfort-on-Main, 26th January 1831. After a course of medical studies at Heidelberg, Marburg, and Berlin, he began in 1853 to practise in his native city, but next year became a *privat-docent* in Tübingen, the year after was called to be professor of Botany at Freiburg, where in 1859 he was appointed ordinary professor. In 1867 he obeyed a call to Halle, and in 1872 to Strasburg, where he was the first rector of the newly reorganised university. He died at Strasburg, 19th January 1898. As a botanist, De Bary is famous especially for the contributions he

has made to our knowledge of the morphology and physiology of the fungi and the Myxomycetæ. Of his numerous works in these departments, the *Comparative Anatomy of Phanerogams and Ferns* has been translated (1885); as also the *Morphology of Plants*, and *Lectures on Bacteria* (1888).

Debateable Land. See BORDERS.

Deben'ture is a deed or instrument issued by a company or public body as a security for a loan of money. It charges the property of the company with the payment of interest, and the repayment of the principal at some fixed period, usually three, five, or seven years. Debentures vary in their terms, style, and legal incidents according to the statutes under which power is given to issue them; but the most common form is that of the railway debenture, which is a mortgage issued under the Companies Clauses Act, 1843, and containing an assignment of the whole undertaking and receipts of the company. Debentures of a company registered under the Companies Act, 1862, generally create a charge on the property of the company, but are sometimes merely bonds, or in the form of promissory notes. In many cases the issue of debentures has been superseded by the issue of debenture stock, which, with the interest thereon, is a charge on the undertaking of the company prior to all shares or stock of the company. It is capable of being transferred in any amount, and does not, like a simple debenture, represent the title of the original holder by an instrument complete in itself, but requires entry in a register.

The term debenture is also used by officers of excise to denote a certificate entitling a merchant who exports goods to receive bounty or drawback.

Debit and Credit. See BOOK-KEEPING.

Deborah (Hebrew, 'bee'), the 'Mother in Israel,' a Hebrew prophetess, wife of Lapidoth, judged Israel under a palm-tree on Mount Ephraim between Ramah and Bethel. Through her patriotism the Hebrews were delivered from the yoke of the Canaanites, under which they had lain for twenty years. She united several of the tribes of northern Israel under Barak (= Carthaginian Barca, 'lightning'), who completely destroyed a great army of the Canaanites at Taanach in the plain of Esdraelon on the brook Kishon. Sisera, the Canaanite leader, fled, and was murdered in his sleep by Jael. 'The land had rest forty years.' The song of Deborah (Judges, v.) is an inspired utterance of the most joyful enthusiasm. See Ewald, *Die poetischen Bücher des alten Testaments* (vol. i. new ed. 1865), and the eloquent passage on 'this Hebrew Boadicea' in Coleridge's *Confessions of an Inquiring Spirit*.

Debreczin, a town of Hungary, in the midst of a wide plain, 130 miles E. of Pesth by rail. It is a large straggling place, indeed really a collection of villages. Notwithstanding its generally squalid character, Debreczin is possessed of some very handsome public buildings, including a town-hall. The Protestant college, with faculties of law and theology, has a valuable library, and physical and zoological collections, is the chief Reformed college in Hungary, and has over 1000 students; several churches, a monastery, a bank, and theatre. The inhabitants are largely dependent on agriculture; enormous herds of cattle graze on the fertile stretches of plain. There are also manufactures of soap, saltpetre, sausages, ham, and tobacco-pipes, which are famous throughout Hungary, and a great steam flour-mill. There is much trade in cattle, swine, and grain. Pop. (1881) 51,122, all Protestants but 2000. The 'Rome of the Calvinists,' Debreczin

was long the headquarters of the Reformed faith, and its inhabitants suffered much for their religion. The town took a prominent part in the revolution of 1849, and was for some months in that year the seat of the national diet.

De Broses. See BROSSES.

Debruised, a heraldic term applied to an animal having a bend or other ordinary placed over it.

De Bry, THEODOR, a goldsmith and copperplate engraver, born at Liège in 1528, who settled in Frankfurt-on-Main about 1570, and established a printing-house there. The most important of the works issued from his press is the collection of *Voyages to the East and West Indies*, published in Latin (25 parts, 1590-1634) and German (27 parts, 1590-1630). He died in 1598, leaving two sons to complete the undertaking.

Debruised.

Debt means a definite sum of money owed by A to B. The word includes the right of the creditor as well as the liability of the debtor. It is contrasted with the liability for damages, or other unliquidated liability. In England there is, in general, no method of securing debts before they are payable (what is called a garnishee order applying only to judgment debts); but future and contingent debts may in Scotland be secured by arrestment or inhibition where the debtor's solvency is doubtful. The main division of debts in Scotland is into movable and heritable—the former being primarily chargeable only upon the debtor's personal funds, although they may, by adjudication, be made also a charge upon his real estate; and the latter being directly a charge upon his real estate. The former have always been treated as personal estate as far as regards the creditor's succession, while until 1868 the latter were considered as heritable estate. Now, there is no distinction. In England also a debt may be secured on the debtor's real estate, as by mortgage or equitable lien; but these mortgages were always regarded as personal estate, although until 1874 the formal title was in the heir, not the executor. In England, a debt of record is one proved to exist by the records of a court. The most important are judgment debts, which have not only certain facilities in execution and attachment, but must be paid in full out of the personal estate before any debts due on contract. A judgment debt, when delivered in execution, creates a charge on the debtor's real estate, as if he had given a mortgage. Specialty debts in England are debts by contract created by a deed or an instrument under seal. Such debts were formerly entitled to a preference over simple contract debts, such as the liability under a bill of exchange. But that was altered in 1869. In the administration of a deceased's estate, the order of preference among debts (as recognised by the Judicature Act of 1873) is (1) expenses; (2) crown debts; (3) judgment debts; (4) recognisances and statutes; (5) special and simple contract debts. Under the Judicature Act in England, and at common law in Scotland, in the winding up of the estates of deceased persons, provision must be made for the valuation of contingent and future liabilities or debts, very much in the same way as under sequestration or liquidation proceedings in cases of bankruptcy.

In bankruptcy there are certain preferential debts, such as taxes and rates, wages and salaries. In England, actions of debt, when on contract under seal, must be brought within twenty years; on other contracts, within six years. The time in both

cases is taken from the accruing of the cause of action—i.e. the breach of contract; but if a subsequent acknowledgment in writing has been made by the party liable, or he has paid the debt in part, or paid interest, the time will run from such subsequent act. In Scotland, on the other hand, obligations generally, and especially such as correspond to the specialty contracts of England, are only subject to the long negative prescription of forty years, but tradesmen's accounts and some others prescribe in three years (see PRESCRIPTION). The debtor's summons, commonly used in England, is a summons to pay generally a trade debt (not less than £50) within so many days, otherwise an act of bankruptcy will have been committed, and a bankruptcy petition will be presented.

IMPRISONMENT OF DEBTORS.—Except in the case of fraud, no debtor can be imprisoned in England for a debt below £20, exclusive of costs. But such debtors, if ordered by an insolvent or county court to pay the debt by instalments, or otherwise, may, if they make default, be committed by the court to prison for forty days. In Scotland, the limit below which imprisonment for debt is incompetent is £8, 6s. 8d. If a debtor escapes after arrest, and before imprisonment, the officer of the law in charge of the process is liable for the debt.

In England, imprisonment for debt was abolished by the Debtors Act, 1869, except in certain cases, the most important of which are those of a defaulting trustee and of a judgment debtor who is able, but refuses to pay. In certain actions for £50, defendants about to leave the country may be imprisoned, and under the Absconding Debtors Act, 1870, insolvent debtors may be arrested to prevent their evading bankruptcy proceedings by going abroad. In Scotland, imprisonment for debt was abolished by the Debtors (Scotland) Act, 1880, 43 and 44 Vict. chap. 34, generally known as Cameron's Act; except in the case of taxes, fines, or penalties due to the Queen, and rates and assessments lawfully imposed, and also sums decreed for alimony. By the Civil Imprisonment (Scotland) Act, 1882, 45 and 46 Vict. chap. 42, imprisonment was further limited, (1) in the case of assessments, to a period of six weeks; (2) in the case of alimony, to debtors wilfully failing to pay, though possessed of means, or being able to earn the same. These acts do not exclude imprisonment where a debtor is *in meditatione fugæ*, or where he refuses to perform an obligation *ad factum prestandum*. What is known in Scotland as a *fugæ* warrant is granted where it appears that a debtor, in a debt above £8, 6s. 8d., is about to leave the country without providing for its payment. Security must be given to present the debtor when decree is obtained, so that he may be charged to pay. It is thought this remedy does not apply to foreigners travelling through Scotland for pleasure.

In the United States originally imprisonment of debtors was adopted as a part of the common law, but at the present time imprisonment for debt, except in case of fraud, or of an absconding debtor, is believed not to exist in any of the states. Congress, empowered by the United States Constitution to make a uniform bankrupt law, has exercised this power, and subsequently repealed the law of imprisonment (see BANKRUPT); and now, by Revised Statutes 990 and 991, no person can be imprisoned for debt by any process issuing out of the courts of the United States, in any state where by the laws of the state imprisonment for debt has been abolished. Most of the states, by constitutional provision (either by Article of the Constitution, or by Declaration in Bill of Rights), have prohibited arrest or imprisonment for debt, while the other states, either by direct statutes prohibiting imprisonment for debt, or by poor debtors laws, or by

insolvent laws, secure the same result; it being held to be against public policy to deprive a man, by imprisonment, of the power to pay his debts, and make him a direct charge upon the state. These statutes and constitutional provisions are not in conflict with the provision of the United States Constitution, prohibiting the states from making any law impairing the obligation of contracts, as imprisonment for debt is no part of the contract; but they do not in general apply to arrest in actions for tort. In some states, statutes providing for the arrest of a defendant in actions for breach of promise have been held to be unconstitutional, as in conflict with the provisions of state constitution prohibiting arrest for debt, that provision applying to *mesne* as well as final process. If a person in custody of the court is discharged by giving bail for the payment of a fine or other money within a certain specified time, the bail may be forfeited, but no commitment can be made for the payment of the fine, as that would be imprisonment for debt, but a judge may imprison for personal examination in act of execution.

RECOVERY OF DEBTS.—With respect to the recovery of debts, if the debt exceeds £50 in amount, the creditor must, in England, proceed in one of the superior courts of law; and, in Scotland, he may proceed either before the superior court or before the sheriff-court. If the debt do not exceed £50, the creditor may proceed in the English county court, or the sheriff-court; if below £25, in Scotland he must proceed in the sheriff-court.

In England, the first step to recover a debt not exceeding £50 in the county court, is for the creditor to go to the registrar of the district within which the defender resides, or to the jurisdiction of which he is on some other ground amenable. He there fills up a printed form, called a *plaint*, shortly stating the claim and the ground of it. The registrar upon this issues a summons, and gives it to the bailiff of the court, who serves a copy of it on the defendant. This summons names a day on which the parties must appear before the judge. No written pleadings are in general necessary; but if the debtor has any special defence—such as, that he has a counter-claim against the plaintiff, or that he (the defendant) was a minor at the time the debt was contracted, or that he has been discharged under the bankruptcy acts—he must give the creditor notice in writing five days before the hearing. If he simply denies the debt, he has nothing to do but to attend the hearing, with what witnesses he may require. If the witnesses are not likely to come voluntarily, summonses to enforce their attendance (as well as the production of documents) may be obtained at the registrar's office. At the hearing, the judge (unless a jury have been required) proceeds himself in a summary way to try the cause. He examines the witnesses on oath, keeping no record of the evidence; and, on hearing the parties, gives judgment at once. If he decides for the plaintiff, he may make the sum payable at once, or in cases below £20, by instalments. The costs are according to a fixed scale, which may be seen in the court or in the registrar's office.

There are provisions for parties having their case tried by jury, and also for appeal on questions of law. Either party who wishes it, may ask for a jury; and if the sum claimed exceed £5, the demand must be complied with. If there be a jury, the number of jurymen is five, and their verdict must be unanimous. The party dissatisfied with the verdict may ask for a new trial, and the judge, if he thinks right, may grant it on such terms as he thinks reasonable. This power to try by jury is used very rarely indeed—less than one per cent. of all the cases which go to trial being tried in that

manner. The right to appeal is against decisions in point of law, and against the admission and rejection of evidence. The appeal is to a Divisional Court of the High Court of Justice. It is taken by requiring the judge to state a case for the opinion of the higher court, and thereafter entering it for discussion there. The appellant must give security for the costs of the appeal, and (if defendant) for the amount (both of principal and costs) contained in the judgment. The right of appeal is not much exercised, and the parties have it in their power to agree beforehand (in writing) that there is to be none. Leave to appeal is required where the sum sued for is less than £20. Before trial, cases may be removed by *Certiorari* (q.v.) to the High Court of Justice, but that is in the discretion of the superior judge.

When judgment is for the creditor, and the order for payment is not complied with, execution may issue against the goods of the debtor. Although imprisonment for debt was (in the general case) abolished in England in 1869, it still remains the law that in the county courts, in certain cases, the debtor may also be imprisoned. The debtor is summoned to show cause why he has not obeyed the judgment. At this hearing (whether the debtor attend or not), the creditor may get an order to commit, if he can show, to the judge's satisfaction, that the debtor has had since the judgment sufficient means to pay, and has refused to do so. This imprisonment may be for six weeks, but it is not held to be equivalent to payment. Of course the debtor is protected by bankruptcy or liquidation.

Although it is competent to proceed in the county courts for sums as large as £50, they are not much used for sums above £20. When the debt does not exceed £20, there is a certain compulsion on the creditor to resort to the county court, for if he resort to a superior court, and recover no more than that sum, he will have no costs, unless he satisfies the court that he had sufficient reason for taking that course. In point of fact, there is only about one case for a sum exceeding £20, for a hundred which do not exceed it; and the average amount sued for is between £2 and £3. The law upon this extremely important practical matter is now consolidated in the County Courts Act, 1888.

In *Scotland*, under the Small Debt Act, 1 Vict. chap. 41, as amended in 1833, debts not exceeding £12 may be recovered in the Sheriff Small-debt Court. The creditor takes two copies of his account to the office of the sheriff-clerk for the circuit in which the debtor lives; from him he obtains a summons, in which the day for the trial is fixed; and this summons he takes to an officer of the court (sheriff-officer), who serves a notice, with one of the copies of the account, on the debtor, at least six days before the trial. The presence of a witness at citation was dispensed with by the Citation Amendment Act of 1871, which also abolished lockhole citation; and under the Citation Amendment Act of 1882, citation by registered letter instead of by messenger-at-arms will be allowed in the general case, it being formerly allowed only where the debtor hid himself, or refused access, or had gone for forty days. Both parties may employ an officer to cite witnesses. The creditor must appear at the trial, either by himself or by one of his family, or by such other person as the sheriff may permit. Law-agents require special permission to appear, unless where both parties consent. If the defender intend to plead a counter-claim, he must cause a sheriff-officer to give a copy of it to the pursuer, at least one free day before the trial; otherwise, there are no written pleadings. On the day fixed for the trial, if the debtor does not appear, decree is given against him, with expenses, as a

matter of course; against which he can afterwards be 'reponed' only on consignment of the expenses and a sum of 10s. If both parties appear, the judge hears the case. If the pursuer or the defender have clearly no good ground of action or defence, he disposes of it at once; but if not, he examines the witnesses on oath. No record of the evidence is taken. At any time before judgment, the case may be remitted to the 'ordinary court' of the sheriff, where it is conducted by agents on written pleadings and written proof. Otherwise, the whole proceedings are concluded in one day, adjournments not being permitted, except in special cases. After judgment, there is no appeal, except on the ground of want of jurisdiction, malice, oppression, or wilful neglect of the statutory forms, in which cases there is an appeal to the Court of Justiciary. The judgment provides for execution against the debtor's goods. This process is often used for the recovery of small rents.

The Debts Recovery Act, 1867 (30 and 31 Vict. chap. 96), has extended the Scottish small-debt jurisdiction, with important alterations, to £50. The class of debts that may be sued for between £12 and £50 has been limited to those which most require summary proceedings—namely, those which prescribe if not sued for within three years, such as all ordinary merchants' accounts, and accounts for professional services or for servants' wages. The principal differences between this and the proper small-debt proceedings are, that agents are allowed to appear; that there are two days in court, one at which the grounds of action and defence are stated, and an adjourned one, at which the witnesses are examined; that the judge makes a note of the pleas of the parties; that a record is kept (if required) of the admissions in fact and of the evidence; and that there is a right of appeal, if the debt does not exceed £25, from the sheriff-substitute to the sheriff, and if it exceed £25, also to the Court of Session. If the judge be not asked to take a note of the evidence, there is no appeal in matters of fact. All the fees and costs, whether payable to the sheriff-clerk, the officers of the court, or the law-agents, are distinctly stated in the act, and must be hung up in every court. In other respects, the proceedings are analogous to those in the Small-debt Court, and, like them, may proceed either at the principal town of the county, or at one of the towns at which sheriff's circuit-courts are held.

In England and in Scotland there are other courts which deal with the recovery of debts beside the county courts. The Sheriff's Court of the City of London has a jurisdiction similar in general to that of the English county courts; and there are local courts, such as the Court of Passage at Liverpool, and the Manor Court at Bradford, which exercise jurisdiction in small as well as other debts. In Scotland, the magistrates of royal burghs, and the justices of peace, possess a small-debt jurisdiction for debts not exceeding £5 in amount. In the latter case, the Royal Commission of 1870 recommended a reform, especially as regards fees and execution against goods. The widespread belief that a corpse could be attached for debt was a vulgar error.

LAW OF DEBTOR AND CREDITOR.—In the history of execution for debt the march of social progress may be traced in earlier times. On the one hand, lending is confounded with alms-giving; and the exaction of interest, and even of capital, is regarded as an act of inhumanity towards the poor. On the other hand, when the creditor's rights come to be recognised in a legal sense, there seem to be no limits set to them. If he is entitled to exact the debt at all, he is entitled to seize the goods of the debtor; and if the debtor has no goods, he is

entitled to his services. But the possession of his services implies the possession of his person; and the possession of his person implies the possession of his life. The person of the individual, the father of a family, brings along with it right over his wife, his children, and his slaves. The creditor thus becomes the absolute master of the life and liberty of his debtor, and of all those who are dependent upon him. The arrangements of the Mosaic Law are an illustration of the manner in which, in the ruder forms of society, the laws of debt thus combine a degree of lenity with a degree of severity which are equally alien to modern views. If an Israelite became poor, it was a duty to lend to him, and no interest was to be exacted either in money or in produce. If he was a foreigner, the case was different, and the taking of interest was legal (Exod. xxii. 25; Deut. xxiii. 19, 20; Lev. xxv. 35-38). When the Sabbatical year arrived—i.e. at the end of every seven years—there was a general remission of debts as between Israelite and Israelite; and the near approach of the year of remission was not to be recognised as an apology for declining to lend to an indigent brother (Deut. xv. 1-11). Pledges, it is true, might be taken, but even here the same humane principles prevailed. The upper millstone was sacred, for to take it would be to deprive the debtor of the means of subsistence. If raiment was the pledge, it must be returned before nightfall, when it might be required for a covering (Exod. xxii. 26, 27); and the widow's garment could not be taken in pledge. In strange contrast to this is the provision (Lev. xxv. 39) that a poor Israelite may be sold to one possessed of substance, even when modified by the special provision that he shall serve as a hired servant, not as a bond-servant, and shall be set at liberty when the year of jubilee arrives. Michaelis says that the judicial procedure for debt was quite summary, the most important causes being decided probably in a single quarter of an hour; and he remarks that Moses nowhere thinks it necessary to mention how a debt was to be proved before a judge. There was, however, an extensive system of appeal; from the judge over 10, the case was carried to the judges over 50, 100, and 1000, and finally to Moses himself. As every Israelite was entitled to claim the land of his fathers at the jubilee year, and thus to place matters on the footing on which they were after the settlement in Palestine, debts and burdens on land were limited to claims to the fruits of forty-two harvests; but houses, with the exception of those of the Levites, might be sold in perpetuity (Lev. xxv. 29, 30, 32, 33). Children were often given in pledge (Job, xxiv. 9), and ultimately into slavery, in payment of debt (2 Kings, iv. 1). Subsequent to the Captivity, the pressure of debts upon the poor became so intolerable, that Nehemiah espoused their cause, and insisted on a general remission (Nehem. v.), exacting from the rich an oath that they would never afterwards press for payment.

Both in Greece (Plut. *Vita Solonis*, 15) and in Rome (A. Gell. xx. 1, 19; Liv. ii. 23) the creditor had a claim to the person of the debtor. Previous to the time of Solon this arrangement had produced consequences at Athens closely analogous to those which afterwards led to the struggles between the patricians and plebeians at Rome; and his abolition of it forms one of Solon's many claims to the character of an enlightened legislator. By the Twelve Tables, it was enacted at Rome that if the debtor admitted the debt, or had had judgment pronounced against him for it, thirty days should be allowed him for payment. At the expiration of that period he was liable to be given into the hands of his creditor, who kept him sixty days in chains, exposing him on three market days, and proclaiming his debt. If no one stepped in to release him, the

debtor at the end of that time might be sold for a slave, or put to death. If there were several creditors, the letter of the law permitted them to cut their debtor in pieces, sharing him in proportion to their claims; but Gellius says this law was never enforced. To treat him as a slave, however, and make him work out the debt, was the common practice; and the children in his power, in accordance with the whole constitution of society at Rome, followed his condition. The Lex Poetelia (326 B.C.) alleviated the condition of the debtors (*necri*) by prohibiting the voluntary alienation of personal freedom. It is uncertain whether it also put an end to the involuntary alienation by the execution of judgment debts. 'During the Republic a debtor could not be taken as a slave to satisfy a judgment debt. The imprisonment of the debtor in a public prison took the place of his reduction to slavery' (chap. vii. 71, 1). Great prominence was given by the plebeians to a change in the laws of debtor and creditor, on the occasion of their first secession, in 494 B.C.; and subsequently during the whole course of the struggles between the two orders. At Rome the creditor was not bound to maintain his debtor in prison, but it was an offence to prevent food and bedding being supplied. In 320 A.D. Constantine abolished imprisonment for debt, unless the debtor was contumacious.

During the feudal period the person in general was not attachable for debt, imprisonment being inconsistent with the duties of warlike service, to which every man was bound; and it was for the encouragement of commerce, and in consideration of the merchant having to deal with strangers and foreigners, that it was first introduced by the mercantile communities of Europe.

For further information on this and cognate subjects, see other articles in this work, such as ARRESTMENT, ATTACHMENT, BANKRUPTCY, BOND, CESSIO BONORUM, CONTRACT, DILIGENCE, HUSBAND AND WIFE, INFANT, SANCTUARY, &c. For the history of the law of imprisonment for debt, see, for England, Reeves's *History of the Law*, and for Scotland, Bell's *Commentaries*. For archaic systems of execution for debt, such as the Indian *darna*, or fasting at the door of the debtor, see the works of Sir Henry Sumner Maine.

Debt, NATIONAL. See NATIONAL DEBT.

Debut (*début*), a French word which has been adopted into the English language, signifying generally a beginning or entrance, but specially applied to the first appearance of an actor or actress on the stage at all, or to a first appearance in a particular theatre. In these circumstances, the actor is called a *débutant*; the actress, a *débutante*.

Deca (Gr., signifying 'ten'), a prefix of frequent occurrence: as in *Decapolis*, a group of ten cities; *decalogue*, the ten commandments; *decamètre*, a measure of ten metres, &c. From *deca* is formed *decade*, a collection or group of ten. In the calendar of the French Republic the term *decade* was used to designate their week of ten days, the various days of which were named *primidi*, *duodi*, *tridi*, *quartidi*, *quintidi*, *sextidi*, *septidi*, *octidi*, *nonidi*, and *decadi*. See CALENDAR.

Decachord, an ancient Greek instrument of ten strings (hence the name), triangular in shape; also a kind of large guitar with ten strings.

Decagon is a plane geometrical figure of ten sides. When the sides are equal, the figure is called a regular decagon.

Decalogue (Gr. *dekalogos*, 'ten words' or 'sentences'), the ten commandments. The 'ten words,' as they are called in Exodus xxxiv. 28, and elsewhere, are prefixed to the collection of laws called the 'Book of the Covenant' (Ex. xx. 22 to xxiii. 33), and with it form part of the 'Prophetical Narrative' of the Pentateuch (here extending from

Ex. xix. 3 to xxiv. 15). They are quoted at length in Deut. v. 1-21, and, besides minor differences, with remarkable extensions and variations in the fourth, fifth, and tenth commandments. The Divine rest after Creation is given as the ground of the fourth commandment in Ex. xx. 11, the first part of that verse being based on Ex. xxxi. 17b, and the second part on Genesis, ii. 2b, both of which form part of the 'Priestly Narrative' of the Pentateuch. In Deuteronomy this *reason* for the commandment is omitted, and appended to the commandment there is a statement of the *purpose* of the Sabbath (based, indeed, on Ex. xxiii. 12), 'in order that thy man-servant and thy maid-servant may rest as well as thou,' and of the *motive* to keep it—viz. Israel's gratitude to Jehovah for deliverance from his own servitude in Egypt. It has been conjectured that the Decalogue in its original form was entirely without comments, and that all the commandments were expressed with the same terseness and brevity as in the first, sixth, seventh, eighth, and ninth.

The prohibitions of other gods and of image-worship being closely connected, and supported in common by the reason annexed in Ex. xx. 5, 6, were even in ancient times taken together as *one* of the Ten Words; the number ten being made out of the rest in various ways. The Jews commonly considered the prefatory words in Ex. xx. 2 (Deut. v. 6), 'I am the Lord, &c., as forming the first Word. The Lutheran Church, following another ancient Jewish division, divides the prohibition of evil concupiscence into two—the ninth and tenth commandments, making 'Thou shalt not covet thy neighbour's house' (which in Ex. xx. 17, is mentioned first) the ninth. The Roman Catholic Church, following Augustine, finds the ninth commandment in the first clause of Deut. v. 21, 'Thou shalt not covet thy neighbour's wife.' In the other Protestant Churches, and in the Greek Church, as also in Josephus, Philo, and the earliest Church Fathers, the prohibitions of other gods and of image-worship are counted as the first and second commandments, and that of evil desire as *one*—viz. the tenth. The Catholic and Protestant Churches agree in making 'Honour thy father and thy mother' begin the second table of the Decalogue; but Delitzsch, Oehler, and other scholars hold that the ten commandments fall into two sets of five, the first including the commandments of *piety* to God and to those whom he has invested with natural authority; the second, the commandments of *probity*, or of duty to one's neighbour. See PENTATEUCH; Driver's *Notes on Lessons from the Pentateuch* (New York, 1887); Stanley's *Christian Institutions*, chap. xvii.

Decameron, the great work of Boccaccio (q.v.).

Decamps, ALEXANDRE-GABRIEL, a celebrated French painter, was born at Paris in 1803. A great portion of his childhood was spent in a lonely part of Picardy among the peasants, which seems to have given him a lifelong distaste for the ways of cultivated society. He studied in a desultory manner under Bouchot, Abel de Pujol, David, and Ingres, but he saw nature in his own way, and stamped the small pictures of animals which he then produced with his own individuality. His want of a thorough grounding in art, and his disinclination for systematic study, told against him, and prevented him from working with perfect ease and mastery. His effects were attained by repeated paintings, and his pictures exhibit a strong impasto, which he scraped with pumice-stone, and again retouched. In 1824 he spent the summer in Switzerland, and in 1827-28 he travelled in Italy and passed to the Levant, where he found

congenial subjects, of the class that Delacroix afterwards treated, which greatly occupied his brush, and which attracted attention in the Salon of 1831. He aspired to treat historical and religious subjects: his 'Defeat of the Cimbri' (1834) attained a great success. He was made a chevalier of the Legion of Honour in 1839, and became officer in 1851. He died at Fontainebleau from a hunting accident, 22d August 1860. His works prove him to have been a powerful colourist; they are effective in composition and the distribution of light and shade, and show a fine appreciation of the wilder and more picturesque aspects of man and nature. Since his death they have realised large prices, his water-colour of 'Children let out of a Turkish School' (1842) fetching 34,000 francs in Paris in 1861. See his *Life* by Moreau (1869).

De Candolle, AUGUSTIN PYRAME, an eminent botanist, descended from an ancient noble family of Provence, was born at Geneva, 4th February 1778, and was first drawn to the study of botany by the lectures of Vaucher. In 1796-97 he studied chemistry, physics, and botany in Paris, where in 1797 his earliest work, on lichens, was published. Other works quickly followed, including his *Astragalologia* (1802), and his valuable *Essais sur les Propriétés Médicales des Plantes* (1804). In 1802 he was elected to an honorary professorship in the Academy of Geneva, but remained in Paris, and delivered his first botanical lectures in the Collège de France in 1804. His *Flore Française* appeared in four volumes in 1805. Employed by the government, he visited all parts of France and Italy in 1806-12, investigating their botany and agriculture. The results of his journeys are partly embodied in a supplement to the *Flore*. He was appointed in 1807 to a chair at Montpellier, where he lived from 1810 to 1816; he then retired to Geneva, where a professorship of Botany was founded for him, and where he spent the remainder of his life. He died 9th September 1841. De Candolle was an industrious writer, and the fruits of his valuable studies in systematic botany and the properties and natural affinities of plants are embodied in a considerable number of works. The greatest of these, his *Regni Vegetabilis Systema Naturale* (vols. i. and ii. Paris, 1818-21), was commenced on too grand a scale, and was continued within more reasonable limits in the *Prodromus Systematis Naturalis Regni Vegetabilis* (17 vols. 1824-73, the last ten by his son and others). De Candolle bequeathed his collections—including a herbarium of more than 70,000 species of plants—to his son, ALPHONSE DE CANDOLLE (born 1806), on condition of his keeping them open to the public, and of his carrying on the *Prodromus*. That son, himself a botanist of no mean fame, published several works of note, the most important being *Géographie Botanique* (2 vols. 1855) and *Origine des Plantes Cultivées* (1883). He also edited the *Mémoires* of his father (1862).

Decapoda. See CRAB and CRUSTACEA.

Decapolis. See DECA.

Decatur, capital of Macon county, Illinois, on the Sangamon River, 39 miles E. of Springfield, at the junction of several railways. It has woollen, planing, and flour mills, and a number of smaller manufactories. Pop. (1880) 9547.

Decatur, STEPHEN, American naval commander, was born in Sinnepuxent, Maryland, 5th January 1779, of French descent, and obtained a midshipman's warrant in 1798. He saw some service against the French, and was commissioned lieutenant in the following year; and at the close of the French war in 1801 he was one of the thirty-six officers of that rank retained in

the reduced strength of the navy. In the war with Tripoli (1801-5) he gained great distinction; his brilliant achievement of boarding and burning the captured *Philadelphus* in the harbour of Tripoli, and then escaping under the fire of 141 guns, Nelson pronounced 'the most daring act of the age.' For this he received his commission as captain in 1804; in 1810 he was appointed commodore. In the war with England in 1812 he captured the frigate *Macedonian*, but in 1814 he was obliged to surrender, after a resistance that cost him a fourth of his crew, to four British frigates. In 1815 he chastised the Algerines for their piracy, and compelled the dey to declare the American flag inviolable; and he obtained indemnities for violating treaty stipulations from the bey of Tunis and the pasha of Tripoli. He was appointed a navy commissioner in 1816, and was killed in a duel by Commodore James Barron, near Bladensburg, Maryland, 22d March 1820.

De Caus. See CAUS.

Decazeville, a town in the French department of Aveyron, 110 miles NNE. of Toulouse by rail, with iron and coal mines near by, and extensive blast-furnaces and ironworks employing 3000 hands. Pop. (1886) 7981.

Deccan (*Dakshin*, 'the south'), a term applied sometimes to the whole peninsula of Hindustan to the south of the Vindhya Mountains, which separate it from the basin of the Ganges, and sometimes restricted to that portion of the same which is rather vaguely bounded on the north by the Nerbudda, falling into the Gulf of Cambay, and on the south by the Kistna or Krishna, flowing into the Bay of Bengal. Independently of this indefiniteness of meaning, the name, like that of the Carnatic (q.v.), is rather of historical interest than of actual use.

Deceased Wife's Sister. By the laws of the United Kingdom, marriage with the sister of a deceased wife is prohibited as being incestuous. At one period this was the universal law of Christendom—both branches of the Christian church, the Eastern as well as the Western, having united in condemning it. The early canon law forbade marriages between relatives to the seventh degree (afterwards changed to the fourth degree by a council of Lateran), and declared that affinity must be treated in the same way as consanguinity (see CONSANGUINITY). The foundation for this was the Mosaic law respecting the intermarrying of kindred, as given in Leviticus xviii. As is well known, however, the canon law was not at all times stringently enforced by the ecclesiastical courts, and we find that papal dispensations—a fruitful source of revenue to the church—were not uncommon at certain periods of history. A noted historical instance is the case of Henry VIII. and Catharine of Aragon. The opinion of the 19th century, however, tends to run counter to the canon law on the subject, as adopted by the Reformed Churches; and the law prohibiting marriages with a brother's widow or a deceased wife's sister has been abrogated in every state on the continent of Europe, in the United States, and in most, if not all, the British colonies. Great Britain alone adheres to the old rule.

In England, though marriage with a deceased wife's sister seems to have been voidable at common law, it was first specially prohibited by the ecclesiastical courts by an act passed in the reign of Henry VIII. (25 Henry VIII. chap. 22). The force of this enactment was, however, soon afterwards somewhat weakened by another statute in the same reign declaring that 'all lawful persons may marry.' The combined effect of both statutes and common law continued to be a subject of

dispute among lawyers down to the passing of Lord Lyndhurst's Act, 1835. The better opinion seems to be that down to 1835 such marriages were binding till they were annulled by decree of the ecclesiastical courts, and therefore if either of the parties died before decree was obtained, the children of the marriage were legitimate, and entitled to inherit. But Lord Lyndhurst's Act put the matter on a clear footing, for it declared all such marriages entered into after its date to be *ipso facto* null and of no effect. And according to the construction which this statute has received, the English courts hold every marriage entered into with a deceased wife's sister to be null, provided the parties have their domicile in England, although by the law of the *locus contractus* the marriage might be quite legal. It was so decided in the famous case of *Brook v. Brook* (1861), where two English people had gone to Altona in Germany to be married.

In Scotland, by the Act 1567, chap. 14, all connections expressly prohibited by the divine law in the 18th chapter of Leviticus are declared incestuous, and punishable by death. The declaration of the Confession of Faith follows in this matter the canon law. According to the interpretation which this Act of 1567 has received from the judges (and the Act 1567, chap. 15, as regards civil effects), it applies to marriages with a deceased wife's sister. And there are not wanting instances where the punishment of death was inflicted for such marriages. Barbara Tannahill, in the beginning of the 18th century, was executed on her own judicial confession, for having had connection with the husband of her deceased sister. (See Hume on Crimes, vol. i. 449). According to the existing law of Scotland, therefore, as expressed in these old statutes, marriage with a deceased wife's sister is prohibited as incestuous, and is null for civil effects as well as punishable criminally. In punishing the offence criminally, the Scottish law is more stringent than the English, incest not being *per se* a crime in England.

Organised agitation in Great Britain for the abolition of the law respecting marriage with a deceased wife's sister dates back to about the time of Lord Lyndhurst's Act. The matter was first brought before parliament in 1841, in which year leave was refused by the House of Commons for the introduction of a bill for the repeal of the law. Since then the subject has been brought before nearly every successive parliament. Its history in the House of Commons may be given briefly as follows: In the parliament of 1847 the bill was twice read a second time. In that of 1853 it was once read a second time, and once rejected on the second reading. In the parliament of 1857 it was twice read a second time. In that of 1859 it was twice thrown out. In that of 1866 it was rejected once. In the parliament of 1868 the second reading was carried four times; and in that of 1874 the second reading was negatived by a small majority. More recently the supporters of the measure have sought to carry it through the House of Lords in the first instance. In 1882 the bill was only thrown out by four votes (there being an actual majority of the lay peers), and in 1883 it was carried on the second reading by five votes, though after passing through committee it was thrown out on the third reading by seven votes. In 1884 the bill was dropped on the second reading in both Houses, and in 1885-86 it was lost in the House of Lords by a majority of twenty-two.

Much controversy has arisen on the religious aspect of this question, and the main hindrance to legislation has been the opposition of the churches. As has been said before, the law is based upon the old Levitical text (Leviticus, xviii. 18), but

the interpretation of this text has given rise to diversity of opinion. The better opinion is that the prohibition refers only to marriage during the lifetime of the wife; and, in particular, this view of the text has been taken by the most learned Jewish rabbis. In the Book of Deuteronomy the Jewish law seems to have allowed and even commanded the marriage of a woman with her deceased husband's brother (Deut. xxv. 5), and it seems hardly reasonable to suppose that the one should be permitted and the other prohibited.

It should be noted that there is no distinct reference to this subject in the New Testament, it being generally admitted that the words of our Lord, 'And they twain shall be one flesh' (Matt. xix. 5), in reference to husband and wife, are used in a metaphorical sense.

The principal arguments (leaving out of view the question of scriptural authority) adduced by those in favour of repealing the law are as follows: That on grounds of social expediency such marriages are to be approved. They are desired by the poorer classes generally, amongst whom they are of frequent occurrence. When a law is out of harmony with the manners and feelings of a people it should be abolished. Secondly, it would, as a rule, be a benefit to the children of a wife who has died when they are in tender years to have their maternal aunt taking the place of mother to them, rather than a stranger. Naturally she would be least likely to act the cruel stepmother. Thirdly, the present state of the law inflicts a wrong on the offspring of such marriages, by their being thereby deprived of their rights of inheritance, and this more particularly in the case of poor parents who cannot afford to shift their domicile (an easy matter for the rich) to the Continent, or one of the colonies. Further, it may happen, in the present state of the law, that one who has been long resident and legally married in one of our colonies, and has returned to settle in Great Britain, may find his children bastardised. In regard to this, the late Lord Cairns has observed: 'If a man, being domiciled in a colony in which it is lawful to marry his deceased wife's sister, do marry her, his marriage will be good all the world over; whereas if a domiciled Englishman, merely resident in such colony, do so marry, his marriage will be bad everywhere.' Finally, experience is in favour of such marriages, for it is said that in other countries where the repeal of the law in question has taken place nothing but good has resulted.

This latter assertion is denied by the upholders of the law, who further assert that by maintaining the law in its present state the unity of conjugal life is cherished, the circle of sisterhood is enlarged, and the growth of domestic intimacy between allied families promoted, which could not be the case were such unions possible. Many, too, have affirmed their belief that by making this change in our marriage laws other changes of a more sweeping nature would be sure to follow (as in the case of Germany), and the sanctity of the marriage tie be thereby disturbed. But this, which is styled the thin-end-of-the-wedge argument, ignores the fact that prior to 1835 such marriages were in England not uncommon, and that not more than one per cent. were set aside by the ecclesiastical courts.

December, the last month of the year. In the old Roman calendar, before the time of Julius Cæsar, the year began with March, and that which is now the twelfth was then the tenth month; hence the name (*decem*, 'ten'). Our Saxon ancestors called it *Mid-winter-month* and *Yule-month*.

Decemvirs, the ten men appointed to codify the law, both public and private, at Rome. Commissioners were first sent to Greece to study the

Greek statute law, and on their return (302 B.C.) all the magistracies were suspended, and a commission of ten patricians (*decemviri legibus scribendis*) appointed with consular powers to reduce the laws to writing. By the end of the next year the code was finished, and after being ratified by the comitia of the centuries, was erected in the Forum inscribed on ten tables of wood. Next year the decemvirate was renewed, and the result of their deliberations was to add two other supplemental tables, from which the whole code bore its official title of the laws of the Twelve Tables (q.v.). The president of both the decemvirates was the notorious Appius Claudius (q.v.).

Deception Island, a volcanic island belonging to the South Shetland group in the Antarctic Ocean, directly south of Cape Horn. Amidst its ice-covered rocks lies a crater-lake, 5 miles in circumference, surrounded by hot springs.

Deciduous Trees (Lat. *de*, and *cadu*, 'falling off') are those which annually lose and renew their leaves. In cold and temperate countries the fall of the leaf in autumn, and the restoration of verdure to the woods in spring, are among the most familiar phenomena of nature, connecting themselves also very intimately with the feelings, habits, and circumstances of mankind. The greater part of the trees and shrubs of temperate regions are deciduous; but within the tropics the forest retains always its luxuriance of foliage, except in countries where the dry season is extremely marked. There many trees lose their leaves in the dry season, and exhibit the same partial suspension of vegetative life. Trees not deciduous are called Evergreen (q.v.). The means of disarticulation of deciduous leaves is described under LEAF.

Decimal Fractions (Lat. *decem*, 'ten') are such as have for their denominator any of the numbers 10, 100, 1000, &c.—i.e. any power of ten (see FRACTION). Thus, $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, are decimal fractions. In writing these the denominator is conventionally omitted, and the fractions expressed thus: 0.7 or .7, .23, .019. That these numbers do not express integers is intimated by the point to the left; and the denominator is always 1, with as many ciphers annexed as there are figures in the decimal. In the third example a cipher is prefixed to 19, because otherwise it would read as if it stood for $\frac{19}{100}$. The expression £5.647 is read, Five pounds and 647-thousandths of a pound; or, Five pounds, and six-tenths, four-hundredths, and seven-thousandths of a pound. That these two readings are equivalent appears from this, that $\frac{5647}{1000} = \frac{564}{100} + \frac{7}{1000}$. It thus appears that the first figure of a decimal to the right of the point expresses tenths of the unit; the second, hundredths; the third, thousandths, &c. In this property lies the great advantage of decimal fractions; they form merely a continuation of the system of notation for integers, and undergo the common operations of addition, multiplication, &c., exactly as integers do. To explain the principles which determine the position of the decimal point after these operations belongs to a treatise on arithmetic.

The disadvantage attending decimal fractions is, that comparatively few fractional quantities or remainders can be exactly expressed by them; in other words, the greater number of common fractions cannot be reduced, as it is called, to decimal fractions, without leaving a remainder. Common fractions, such as $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, $\frac{1}{4}$, $\frac{3}{4}$, for instance, can be reduced to decimal fractions only by multiplying the numerator and denominator of each by such a number as will convert the denominator into 10, or 100, 1000, &c. (The common process is merely an abridgment of this.) But that is

possible only where the denominator divides 10, or 100, &c., without remainder. Thus, of the above denominators, 2 is contained in 10, 5 times; 4 in 100, 25 times; and 25 in 100, 4 times; therefore,

$$\frac{1}{2} = \frac{1 \times 5}{2 \times 5} = \frac{5}{10} = .5; \quad \frac{1}{4} = \frac{1 \times 25}{4 \times 25} = \frac{25}{100} =$$

$$.25; \quad \frac{9}{25} = \frac{9 \times 4}{25 \times 4} = \frac{36}{100} = .36. \quad \text{But neither 3 nor}$$

7 will divide 10 or any power of 10; and therefore these numbers cannot produce powers of 10 by multiplication. In such cases, therefore, and in fact in the case of any vulgar fraction (in its lowest terms) whose denominator contains any other prime factor than 2 or 5, an equivalent decimal cannot be found. If we try to find it, the result is an infinite series, which is called a repeating, recurring, or circulating decimal. Thus $\frac{1}{3} = .6666$, &c., where the 6 repeats for ever—i.e. $\frac{1}{3}$ cannot be expressed as a decimal. The non-terminating result, $.666$, &c., is written $\dot{6}$.

Decimal System. This name is applied to any system of weights, measures, money, &c., in which the standard unit is divided into tenths, hundredths, &c., for the denominations below it, and multiplied by 10, 100, &c., for those above it. The nature of this method of division will be best explained by an example from the French system, where it has been most rigidly carried out. The *mètre* (= 39.37 English inches nearly) is the unit of length, and the foundation of the whole system. For the higher denominations of length, the Greek words *déca*, *hecto*, *kilo*, and *myria*, are prefixed to signify multiplying by 10, 100, 1000, 10,000; so that *décamètre* = 10 *mètres*, *kilomètre* = 1000 *mètres*, &c. The Latin words *déci*, *centi*, *milli*, on the other hand, are used to express division by 10, 100, &c., and thus furnish names for the lower denominations; *décimètre* = $\frac{1}{10}$ of a *mètre*, *centimètre* = $\frac{1}{100}$ of a *mètre*, &c. Similarly with money; the *franc* being the unit, a *déisme* is the tenth part of a franc; and a *centime*, the hundredth part.

In 1865 Belgium and Switzerland adopted the French decimal system of money, weights, and measures. Afterwards the Italian *lira*, the Greek *drachmá*, the Spanish *peseta*, and more recently the Roumanian *lei*, and the Servian *dinar*, were assimilated to the *franc*. Other countries, though retaining each its own special unit coin, divide it into 100 parts—viz. Germany, Austria, Russia, and the United States of America. The following have adopted the metrical system of weights and measures, though rejecting the *franc*: Germany, the Netherlands, Spain, Portugal, Norway, and Sweden. Engineers, too, have their own decimal systems of measurement.

The method of decimal gradation in weights and measures naturally suggests itself to the arithmetician, on account of the *language* of numbers, and the Arabic notation. Practical legislators, however, have pronounced the number *ten* to be most unsuitable as a basis, especially for the purposes of 'retail trade.' In France the prices 1.25, 4.25, 6.75, &c. are extremely common; yet if half a yard of cloth, for example, is bought at 1.25 the yard, the exact price cannot be paid, and the buyer therefore suffers. He is compelled to pay more than the proper value by reason of the limitations inseparable from the decimal system. The analogous price in English money is 1s. 3d., which allows not only half a yard to be sold at the exact price, but even a quarter of a yard. To estimate the loss undergone by the poorer classes in France on account of the imperfections inherent to their monetary system, the most ordinary case will suffice—e.g. if sugar is sold at 25 centimes a pound, then, any one who buys half a pound *must* pay

exactly 4 per cent. more than the proper price. The same serious drawback is inseparable from the monetary system of the United States, as compared with that of Great Britain. In such a case as that just quoted, the poor buyer in New York is defrauded still more than in Paris; whereas, in Edinburgh, London, or Dublin, the buyer will not only lose nothing by such a transaction, but can buy even a quarter of a pound at the proper price.

In 1821, after an able report drawn up by John Quincy Adams, the United States government rejected the metrical system as unsuited to practical life. The question of adopting the French scheme has also been repeatedly discussed in the House of Commons, but though many, in the interests of certain scientific pursuits and international transactions, advocated a change, there seems little probability of uprooting our existing method, with its excellent supply of binary factors, and the much greater ease with which it lends itself to mental arithmetic. Although proposed in 1795, the decimal system in France required repeated legislation before it could gain footing, and though it was made obligatory from January 1, 1840, the people still retain traces of the older and less arbitrary mode of computation, just as the shilling and sixpence still exist in the United States as terms of reference. The centesimal division of the right angle was also proposed at the French Revolution, but has long been abandoned, even in France. It was also used as a basis in dividing the thermometric scale (misnamed *centigrade* for *herzograde*), but Fahrenheit's is often preferred because there are more subdivisions, and because it avoids the use of negative numbers. The application of the system to the division of time was so unworkable as scarcely to tolerate even a trial. There, as elsewhere, the duodecimal mode, as compared with the decimal, is vastly and incontestably superior. For the decimal system in numerical notation, see NOTATION, NUMERALS; and for the system of measurements based on the *mètre*, see *MÈTRE*.

Decimation, a Roman military punishment, whereby when a considerable body of troops committed some grave military offence, which would be punished with death in an individual, the punishment was awarded to one-tenth of them by lot, instead of to the whole number, that so the army might not be too much weakened. The practice was borrowed from the Romans by Essex at Dublin (1599), by the Austrians at Leipzig (1642), and by the French at Trêves (1675); but Blücher tried vainly to employ it against the mutinous Saxon battalions at Liège (1815).

Decius, a Roman emperor, whose name in full was C. MESSIUS QUINTUS TRAJANUS DECIVS. He was born at Budalia, in Lower Pannonia, towards the close of the 2d century, and was sent in 249 by the Emperor Philippus to reduce to subordination the rebellious army of Mœsia. The soldiers proclaimed him emperor against his will, and forced him to march upon Italy. Philippus encountered the forces of Decius near Verona, but was defeated and slain. Decius assumed the government of the empire in the end of the year 249, but his brief reign was one of restless warring with the Goths, fighting against whom he was killed near Abricium in the close of the year 251. In his reign the Christians were persecuted with great severity. At Rome, Antioch, and Jerusalem the bishops were massacred, the great Origen was cruelly tortured, and dreadful cruelties were perpetrated at Alexandria.

Deck, in ship structure, is a horizontal platform extending from one side of a vessel to the other, thereby connecting them together, and forming in addition a flooring to the persons above it, and a

covering to those below it. There are, as a rule, more than one deck in ships of medium size, and in steamers of the larger class—both war and mercantile vessels—there are usually three, four, and even five decks. Modern steamships of great length with three or four decks have, as a rule, two of the decks composed of iron or steel plating in addition to the usual cross deck-beams and longitudinal wood planking. All decks, especially the upper or 'weather' deck, have a slight 'camber' or 'round-down' towards the sides of the ship, in order to dislodge water and contribute to their lateral strength. The several tiers of decks are supported one upon the other by solid iron pillars, and by the ship's transverse bulkheads.

Vessels are classed for various purposes, according to the number of their decks, as 'single-decked,' 'two-decked,' 'three-decked,' and are otherwise distinguished by terms such as 'spar-decked,' 'flush-decked,' 'awning-decked,' according to the deck which is most typically characteristic. A *spar* deck is always the topmost or weather-deck, and stretches flush or level from stem to stern. Below it there is the *main* deck, on which the heavy weights (e.g. guns in war-ships) are carried. Next comes the *lower* deck, and below it again, in very large ships, is the *orlop* deck. The space between the several tiers of decks is conventionally spoken of as '*tween*' or between decks. Above the main deck of two-decked, or the upper of three-decked vessels, there are frequently partial decks erected; the *forecastle* or *top-gallant forecastle* deck being at the fore end, the *bridge* or *hurricane* deck about the mid-length, and the *poop* or *quarter* deck at the aft end. An *awning* or shelter deck is defined by Lloyd's Register Rules as 'a light superstructure, fore and aft, on the main or upper deck proper of the vessel, intended to shelter passengers or cattle, or for the conveyance of cargo either light in its nature or limited in quantity.' For deck cargoes, see MERCHANT SHIPPING ACTS.

Deckance Hemp. See HIBISCUS.

Decken, KARL KLAUS VON DER, an ill-fated African traveller, was born 8th August 1833, at Kotzen, in the Mark of Brandenburg, passed from the gymnasium of Lüneburg, and the cadets' college at Hanover, into the Hanoverian army, which he left after ten years' service (1860) to follow his bent towards travel. On Barth's advice he went to Zanzibar, and started thence on a journey to Lake Nyassa, which failed through the treachery of his Arab guide. Next year he started on a second and successful journey to the mountain-regions of Kilima-Njaro. In the following year, with O. Kersten, he climbed that mountain to the height of 13,780 feet. In 1863 he made an extensive voyage along the east coast of Africa, after which he returned to Europe to plan a great expedition for the exploration of East African rivers. This journey ended in disaster, and Decken was murdered by a Somali on the 25th September. Only five Europeans and six negroes of his company managed to reach Zanzibar. See Kersten's *Von der Decken's Reisen in Ostafrika* (4 vols. 1869-79).

Decker, SIR MATTHEW, a political economist, was born at Amsterdam in 1679. He came to London in 1702, and having embarked in commerce, attained the greatest success; received a baronetcy in 1716, and subsequently sat in parliament. He died 18th March 1749. He published anonymously two pamphlets which were much discussed: one (in 1743) proposed to raise all the public supplies from a tax upon houses; the other, on the decline of Britain's foreign trade (1744), contained many good arguments for free trade.

Decker, THOMAS. See DEKKER.

Declaration, in Criminal Proceedings. In Scotland, the statement made by the prisoner before the magistrate is called his declaration. It is the duty of the magistrate to take this declaration immediately on the prisoner's being brought to him—that is to say, if the prisoner is in his sober senses; but under the Criminal Procedure (Scotland) Act, 1887, the magistrate has power to postpone the examination to a time not later than forty-eight hours after arrest, in order to give opportunity for the legal adviser of the prisoner to appear. Before the examination the prisoner is entitled to have a private interview with his legal adviser, who may be present during the examination. The magistrate must previously inform the prisoner that it is entirely at his own option to declare or not, but that if he chooses to declare, the declaration may be used in evidence against him on his trial. In practice the examination is generally conducted by the procurator-fiscal. The declaration ought to contain the name, age, and designation of the prisoner, the parish and county in which the crime is said to have been committed, and all similar particulars. When completed it must be read over to the prisoner, who, if he is able to write, signs every page of it along with the magistrate. If he cannot or will not write, the magistrate signs it in his stead. There must, moreover, be two witnesses present, who shall sign the declaration, and who, if necessary, can speak to the manner in which it was taken. If the prisoner does not understand English, a sworn interpreter must be employed. The declaration cannot be produced as evidence if the magistrate has delegated the duty of taking it to his clerk, or to any one not a magistrate.

In the United States, when a person is arrested for a felony, the magistrate before whom he is brought takes the statement of the accused prior to the commitment if he desires to make one. The magistrate must act in person, and the prisoner must understand that he may or may not make the statement, and that it may be used against him upon his trial. If he cannot write, or refuses to write, the magistrate must not write his name for him; if he signs it he must first have the opportunity of reading it himself, but may waive his right to read it and ask the magistrate to read it to him. The magistrate may ask questions to bring out the facts. The mode of taking the statement or declaration is in general regulated by statute, and may form a part of the preliminary examination. If taken according to the prescribed forms of law, and as a spontaneous admission of guilt, it is termed a judicial confession upon which an indictment may be found.

Declaration, in Common Law, was the pleading in which the plaintiff in an action at law sets forth his case against the defendant. Since the Judicature Act of 1875, the *Statement of Claim* (q.v.) takes the place both of it and of the former *Bill in Chancery* (see BILL). In the United States the declaration still retains many of the features of the English common-law declaration, but this form is gradually falling into disuse in obedience to the modern tendency to simplify judicial proceedings. Many of the states having adopted one form of civil action, the courts of law have simplified the common-law declaration and adapted it to this form of action. The declaration substituted must be entitled of the court, term, and number, the venue laid, the names of the parties, and the facts necessary to show jurisdiction stated. This is followed by a concise statement in narrative form of the entire cause of action showing the right of plaintiff to recover.

Declaration, in lieu of an oath. See AFFIRMATION, OATH. In the United States, the form of an oath is immaterial, provided it be such as the witness believes is binding upon his conscience. It is essential that the oath, declaration, or affirmation be administered in a manner prescribed by law. Mere technical variations do not affect the validity of an oath, and verbal deviations are immaterial. Perjury may be committed although the person was improperly sworn. No person will be permitted to make a declaration or affirmation unless he has conscientious scruples against swearing or taking an oath. Declaration in lieu of an oath or affirmation is becoming very general throughout the United States.

Declaration, DYING. The rule that secondary or hearsay evidence is inadmissible suffers an exception, both in England and Scotland, in the case of a declaration made by a person convinced of his impending death, and who does not survive the trial of the accused. In cases of murder, the dying declaration of the victim as to the circumstances of the crime is always admitted as evidence on the trial of the prisoner, provided that it was deliberately emitted while the deceased was in possession of his faculties, and that it is proved by credible witnesses. In Scotland, the dying declaration of a witness is admissible even though he is not himself conscious of the danger of death, and in the United States a declaration is frequently admitted, both in civil and in criminal cases, as primary evidence, without regard to the immediate apprehensions of death. In the same country, declarations are also admitted as secondary evidence under circumstances in which the declarant is either actually or presumed to be dead. The principle under which the dying declaration is admitted is that the awful situation of the dying person is as powerful over his conscience as the obligation of an oath, and does away with all motive to disguise the truth. Accordingly the person against whom a dying declaration is put in evidence may be allowed to show that the deceased was not of such a character as to feel the religious obligation of his situation. A dying declaration may be adduced for as well as against a person accused of crime; and there are cases on record in which persons charged with murder have been successfully exculpated by this kind of evidence.

Declaration of Rights. See RIGHTS.

Declarator, a form of action in Scotland. See ACTION.

Declension, a grammatical term applied by the ancient grammarians to the system of modifications called *cases*, which in many languages nouns, pronouns, and adjectives undergo to indicate the various relations in which they stand to other words. The word *Case* means 'falling'; *Declension*, a 'sloping down'; and were applied because that form of a noun used as the subject of a sentence was supposed to be represented by an upright line, and the other forms by lines falling or sloping off from this upright line at different angles. Hence a collection of the various forms which a noun might assume formed the *declension* or *sloping down* of the noun. The English language has no proper declensions at all, having no cases but the genitive, and some traces of a dative, while it has no genders save in the pronouns of the third person. The Sanskrit language again had eight cases; Latin, six; and Greek, five. Groups of nouns forming their case-endings in the same way are called *declensions*. Thus Latin nouns are said to be divided into five declensions. The Latin cases are the Nominative, which names the subject or actor; the Genitive, expressing the source whence something proceeds, or to which it belongs; the Dative, that

to which something is given, or for which it is done; the Accusative, the object towards which an action is directed; the Vocative, the person addressed or called; and the Ablative, that from which something is taken. The Greek has no Ablative case, while the two additional cases of Sanskrit are an Instrumental case, and a Locative case. In time case-endings become rubbed off, and prepositions are used in their stead, thus French and Italian have lost all the Latin cases of nouns and adjectives. Languages of the agglutinating order have, in general, a great abundance of cases. Thus Finnish nouns have fifteen cases; and in Magyar as many as twenty cases may be reckoned. See GRAMMAR and PHILOLOGY.

Declination. If a great circle be drawn through the pole of the heavens and any star, the declination of the star is the portion of the circle intercepted between the star and the equator (see POLE). The place of a point in the heavens is determined by its *right ascension* and *declination*, just as a point in the earth's surface is determined by its latitude and longitude.

Declination Needle, or DECLINOMETER. The magnetic meridian passing through any place on the earth's surface is a vertical plane whose direction is that in which a magnetic needle, free to move about a vertical axis, comes to rest under the influence of the earth's magnetic force. In general, the magnetic and geographical (or astronomical) meridians are not coincident; the angle between is termed the magnetic declination, or

Declination Needle.

(in nautical phraseology) the variation. It is east or west, according as the magnetic is east or west of the geographical meridian. Any apparatus for the measurement of this angle is termed a declinometer, and consists essentially of a means of ascertaining the two necessary elements—viz. the directions, at the place of observation, of the two meridians. The accompanying figure represents one such instrument, the declination needle or compass. Upon a tripod, provided with levelling screws, stands the pillar P, to which is fixed the graduated circle CC. The compass-box B, with the attached vernier V, moves on the azimuthal circle by means of a pivot on the pillar P. Two uprights, U, U, are fixed to the side of the compass-box, on the tops of which rests the axis of the telescope T. A graduated arc, A, is fixed to the bottom of one of the uprights, and the angle of elevation of the telescope is marked by the vernier on the arm E,

attached to the axis of the telescope, on which is hung the level L, for adjusting the instrument previous to making an observation. Inside the compass-box is another graduated circle F, the line joining the zero-points of which is parallel to the axis of the telescope. The compass-box and telescope thus move round together on an axis passing through the centre of the azimuthal circle. When an observation is made, the instrument is first of all levelled, and the telescope directed to a star which is either on the astronomical meridian or whose position with respect to it is known. The reading of the inner circle then gives the declination at once, in the former case; if the latter—i.e. if the star be not on the meridian, the reading of the inner circle has to be corrected by adding or subtracting, as the case may be, the position of the star in azimuth, in order to give the declination. In order to obviate error due to the non-coincidence of the magnetic and geometric axes of the needle, a second reading is taken with the face of the needle reversed; the mean of the two readings is taken as the true declination.

It is found, however, that this instrument only gives results approximately correct, and has in consequence been superseded in observatories and magnetic surveys by a form of the unifilar magnetometer. For an account of the determination of declination by this latter instrument, see MAGNETOMETER. Details as to the value and secular change of the declination at different places on the earth's surface will be found under MAGNETISM.

Decoction, the term applied in pharmacy to the solution procured by boiling an organic substance with water.

Decolorimeter, an instrument for determining the power of portions of bone-black or animal charcoal to abstract colouring matter. See CHARCOAL.

Decomposition is the rather comprehensive term applied to the breaking up of complex substances, or substances of delicate stability, into others which are less complex or more stable. Such breaking up is very familiar in many chemical changes, and may result from increase of temperature, the action of light, the action of ferments and micro-organisms, and so on. The ordinary process of alcoholic fermentation is a good example of decomposition, which takes place in the presence of, and is dependent upon, the life and growth of yeast in the saccharine solution. Similarly the oxidation of nitrogenous organic matters with formation of nitrates, if not dependent upon, is greatly accelerated by the presence of a micro-organism.

The term decomposition is constantly applied in chemistry to the changes which compounds undergo in the most varied circumstances when subjected to change of conditions. See also CHEMISTRY, FERMENTATION, PUTREFACTION.

Decomposition of Forces. See COMPOSITION.

Decorated Style of Gothic Architecture. This style prevailed in England during the reigns of the first three Edwards, or from towards the close of the 13th till near the end of the 14th century. Under **GOthic ARCHITECTURE** it will be shown how the pointed style progressed, and was naturally and logically developed in all its elements, constructional as well as decorative, until skill in execution exceeded originality in design, after which the art gradually deteriorated. The Decorated or second pointed style occupies the position in which these two elements were in full accord and completest development. Hence this is invariably considered the perfect period of Gothic Architecture.

In the Decorated style the simple forms of the

early pointed became more complex. The simple roll is divided into two parts, the mouldings are more numerous and refined, and they are beautifully grouped and proportioned. The pillars consist similarly of clustered shafts or mouldings arranged commonly on a lozenge plan (fig. 1). The caps are usually carved in imitation of natural foliage, and partake of the character of wreaths growing round the caps, instead of springing from the neck-moulding as in the preceding style (fig. 2). The buttresses are encircled with niches and

Fig. 1.—Column, Collegiate Church, Manchester, 14th century.

Fig. 2.—Decorated Capital, York Cathedral.

canopies, and the latter are more elaborately decorated than formerly. The drip-mouldings over doors, windows, niches, &c. are crocketed and formed into an ogee curve at the top, and finished with a finial—in short, every detail is elaborated and richly decorated. But this development is most prominently marked in the tracery of the windows. In the first pointed style this feature is of the simplest character; but in the Decorated

Fig. 3.—Niche, Walpole St Andrews, Norfolk, 14th century.

Fig. 4.—Window, Broughton, Oxfordshire, 1300.

it becomes fully developed, and forms the most prominent characteristic of the style. At first the tracery consists of geometric figures, such as circles, trefoils, &c.; but in the later examples it develops into flowing lines, which in France passed into the 'Flamboyant' (q.v.). This development of the tracery led to the enlargement of the windows, in order to afford space for its exhibition. Large circular windows, filled with tracery, were also introduced (see WINDOW). The early

ornaments became refined, as, for instance, the dog-tooth was enriched into a four-leaved flower, and the ball-flower is also of frequent use. Segmental arches and square lintels are occasionally employed. In the beginning of the 15th century the Decorated gradually passed into the Perpendicular style.

Decoration Day, in the United States, is the 30th of May, on which day the graves of soldiers are visited, and flowers deposited thereon by surviving comrades.

Decorations. See ORDERS, MEDAL.

Decort, FRANS, a Flemish lyrical poet, born at Antwerp, 21st June 1834. At first he was engaged in trade, later he edited newspapers, was secretary to a steamship company, and became in 1861 secretary to the general auditor in the Cour Militaire at Brussels, where he died, 18th January 1878. Decort's poetry deals mainly with the simple joys and sorrows of the family hearth, but it does not lack passion and power. For some years he issued at Antwerp a very popular almanac, *Jan en Alleman*. Various collections of his poems were *Liederen* (2 vols. 1857-59), *Zingzang* (1866), and *Liederen* (1868). In 1862 he published a fine Flemish translation of some of Burns's songs.

Decoy. See WILD-FOWL.

Decoying of Children. See ABDUCTION, KIDNAPPING.

Decree, or, as it is frequently called in Scotland, a Decreet, is a final judgment of a court, whereby the question at issue is set at rest. In England, it used to be commonly applied to the final judgments of courts of equity. For a *decree nisi*, see DIVORCE. *Decree in absence*, in Scotland, is equivalent to a judgment by default in a common-law court.

In the United States, a decree is the order or judgment of a court of equity, admiralty, or a common-law court with equity powers. It may be either final or interlocutory, and is conclusive if all parties in interest have been served with proper notice. It cannot be set aside by an act of congress or the state legislature. By the United States Constitution, the decrees of a competent court having full jurisdiction in one state are equally binding in every other state, and must be received in evidence in all the courts of the United States.

Decree, in Theology. See PREDESTINATION.

Decrepitation is the term applied to the crackling sound heard when a substance like common salt is thrown upon a fire. A series of minute explosions occur, owing to the water between the plates of the crystalline particles becoming expanded by the heat, and ultimately bursting them.

Decrescent, a heraldic term by which the wane of the moon is indicated. A *moon decrescent* is a half-moon with her horns turned to the (heraldic) sinister—i.e. the right of the spectator.

Decretals, collections of the Canon Law (q.v.).

Dedication. See BOOK, PATRON.

Deduction, in Logic, as opposed to Induction (q.v.), is the method of reasoning from generals to particulars, as the latter is from particulars to generals. *Induction* is the mode by which all the materials of knowledge are brought to the mind and analysed; *Deduction*, the process by which the knowledge thus acquired is utilised, and by which new and more complicated inductions are rendered possible. Thus every step in a deduction is also an induction. See INDUCTION and SYLLOGISM.

Dee, a Welsh and English river, issuing from Bala Lake, in Merionethshire, and flowing NE.,

N., and NW. to the Irish Sea. Near Trevor it is crossed by the Ellesmere Canal, on an aqueduct 1007 feet long and 120 high; and also by the stone viaduct of the Chester and Shrewsbury Railway, of 19 arches, each 90 feet span and 150 high. Below Trevor it winds first south-east, and then north-east and north to Chester, which city it nearly encircles. At Chester (q.v.) it is 100 yards broad, and thence runs alongside marshes in an artificial tidal canal 7 miles long, which should admit ships of 600 tons, but which in the autumn of 1888 was reported to be rapidly silting up. Near Connal's Quay, between Chester and Flint, where its width is 160 yards, it is crossed by the great railway swing-bridge, whose first cylinder was laid by Mr Gladstone on 16th August 1887. The Dee ends in the Irish Sea, in a tidal estuary 13 miles long and 3 to 6 broad, and forming at high-water a noble arm of the sea; but at low-water a dreary waste of sand and ooze (Kingsley's 'sands of Dee'), with the river flowing through it in a narrow stream. Its whole course is 90 miles long, and its chief tributaries are the Treveryn, Alwen, Ceirog, Clyweddog, and Alyn. Canals connect the Dee with the rivers of central England. The ancient Britons held its waters sacred; Milton speaks of its 'wizard stream,' and Spenser of the

Dee, which Britons long ygone
Did call divine, that doth by Chester tend.

Dee, a beautiful river of Aberdeen and Kincardine shires, rising at an altitude of 4060 feet among the Cairngorm Mountains, and running 87 miles eastward, till it enters the German Ocean at Aberdeen, where in 1870-72 a mile of its channel was diverted for harbour improvements. It makes a descent of 2084 feet during the first 2½ miles of its course; at the Linn of Dee, 18 miles lower down, tumbles through a chasm 300 yards long, and at one point scarcely 4 feet wide; thereafter flows by Castleton of Braemar, Balmoral Castle, and Balmater; since 1864 has supplied Aberdeen with water; and is still a good salmon river, though not what it once was.—The *Kirkcudbrightshire Dee* issues from Loch Dee (750 feet above sea-level), and flows 38 miles south-eastward and southward, past Threave Castle and Kirkcudbright, to Kirkcudbright Bay. Midway it is joined by the Water of Ken, 28 miles long, a stream of greater volume than its own. It, too, affords fine fishing.

Dee, DR JOHN, alchemist, was born in London, 13th July 1527, and educated there and at Chelmsford, till in 1542 he was sent to St John's College, Cambridge, where for three years he studied eighteen hours a day. One of the original fellows of Trinity (1546), he earned the reputation of a sorcerer by his mechanical beetle in a representation of Aristophanes' *Peace*, and next year he fetched from the Low Countries sundry astronomical instruments. This was the first of many foreign visits—to Louvain and Paris (1548-51), where he lectured on Euclid, to Venice and Presburg in Hungary (1563), to Lorraine (1571), to Frankfort-on-Oder (1578), to Bohemia (1583-89), and even, it is said, to St Helena. He was imprisoned under Queen Mary on suspicion of compassing her death by magic (1555); but Edward VI. had conferred two church livings on him, and Elizabeth showed him considerable favour, twice visiting him at his Mortlake home, and in 1595 making him warden of Manchester College. He was constantly in difficulties, though he claimed to have found in the ruins of Glastonbury a quantity of the Elixir, one grain of which transmuted into gold a piece of a warming-pan. Indeed, he appears to have been as much dupe as deceiver, the dupe of his own assistant, Edward Kelly, during 1582-89. This knave, who had lost both ears in the pillory, professed to

confer with angels by means of Dee's magic crystal (see CRYSTALLOMANCY), and talked him into consenting to a community of wives. In 1604 Dee petitioned James I. to let him clear himself by public trial of the slander that he was a 'caller of divels,' but half a year later he was back at his invocations. He died wretchedly poor, in December 1608, and was buried in Mortlake church. 'A mighty good man he was,' by Aubrey's showing, 'a great peace-maker, a very handsome man, with fair, clear, sanguine complexion, and a long beard as white as milke.' His eldest son, Arthur (1579-1651), was likewise an alchemist, a friend of Sir Thomas Browne. Of Dr Dee's seventy-nine works, only thirteen have ever been printed: the rest are in MS. at Oxford, Cambridge, and the British Museum. They deal with logic, mathematics, astrology, alchemy, navigation, geography, the 'Rosie Crucian Secrets,' and the reformation of the calendar (1583), in which at least he was much in advance of his countrymen. See his *Private Diary*, edited by J. O. Halliwell (Halliwell-Phillipps) for the Camden Society (1842), and a thirteen-page article in Cooper's *Athenæ Cantabrigienses* (vol. ii. 1861).

Deed, EXECUTION OF, the performance of the ceremonies required by law in order to make a deed binding and effectual. These ceremonies in England consist in signing, sealing, and delivering. Signing is usual in practice, but it is open to doubt whether it is strictly necessary in law. When a party, from any cause, is unable to write, it is usual for him to place his mark in the place of signature. But a mark is unnecessary, and signature by another, at request of the party, is enough. Sealing is the most ancient form of authentication of deeds, and comes from the Norman usage. A seal is absolutely essential to the validity of an English deed, but any species of seal is sufficient, and in practice a common wafer is usually affixed. Delivery is the third requisite. Delivery may be made either to the grantee or to another person for him. In the former case, the deed becomes absolute; in the latter, it is called an *Escrow*, and does not yet acquire its full effect. Witnesses are not absolutely required to a deed in England, but in practice it is usual that one witness should attest. Before execution, a deed must be read, if required, by a party to it; and if not read, it is void as to the party requesting. A will (except that of a soldier or sailor in active service) must be in writing, and signed by the testator or by some other person in his presence and by his direction; and two witnesses must attest the signature.

In Scotland, sealing was once essential, but has long fallen into disuse. A deed is now probative on the face of it (i.e. is received as the authentic act of its grantor) if it is signed by the grantor on each sheet, and attested by two witnesses who are either designated in the deed itself, or in a designation added to their subscriptions before the deed is recorded or founded on in court. In case the maker of the deed cannot write, the deed is validly executed by one notary public or justice of the peace signing it for him in his presence and by his authority, and reading it over to him, all in the presence of two witnesses. A parish minister may act in his own parish as notary for signing a will. Holograph deeds—i.e. deeds written throughout in the handwriting of the grantor, are exempted from the rules as to execution; as also, out of favour to trade, are mercantile writings, such as Bills of Exchange.

In the United States, the formalities required for the transfer of real estate are governed by local laws. Generally throughout the states, signing, sealing, attestation, acknowledgment, and delivery are the essential requisites of a valid deed of con-

veyance. The usual form of attestation being 'signed, sealed, acknowledged, and delivered in the presence of us witnesses,' then follow the names of the subscribing witnesses. The grantor must himself sign the deed, or if it is signed by his agent he must adopt the signature as his own in the presence of the subscribing witnesses and the commissioner or other qualified officer. In the United States, a 'deed,' technically speaking, is an instrument under seal; hence a seal, although a mere formality, is essential, except in those states in which seals have been abolished by statute—Alabama, Louisiana, Texas, Virginia, Kentucky, Kansas, and Iowa. Neither wax nor wafer is necessary for a seal, although a wafer is generally used. A scroll with a pen inclosing the letters 'L.S.' is a seal within the meaning of the law, if it is the intention of the party appending it to adopt it as his seal, and by its use a specialty is created, the same as by the use of wax or wafer. It is not necessary to refer to the fact of sealing in the attestation clause. The number of witnesses required is governed by statutes in most of the states. Generally two are required, but in some of the states only one witness is necessary if the grantor can read; and it is believed that in any state a deed otherwise properly executed with but one subscribing witness would be good as between the parties themselves. It has also been held that independent of any statute, a deed signed, sealed, and delivered, without being acknowledged or recorded, is valid as between the parties and their privies, but the provisions of a local statute as to the execution of a deed must be strictly followed, or the deed is inoperative. Delivery, although essential to the execution of a deed, need not be formally made in the presence of witnesses, but may be a matter of circumstance. A deed takes effect from the date of actual delivery, or the date of record. Everywhere in the United States it is the law that deeds of conveyance must be recorded either in the proper office of the county in which the land lies—or if the conveyance be by grant or letters patent from the state or United States, the record must be made in the land office of the state or United States. The recording of a deed has the force of seisin and possession under the English law. Any estate less than a fee may be conveyed by deed with single acknowledgment, but if the estate sought to be conveyed is a fee, the husband and wife must join in the deed and acknowledge it separately. Deeds of conveyance of lands sold at judicial sale, or for taxes for several successive years and unredeemed made by the sheriff of the county, and deeds made in pursuance of a decree of court by the officer appointed for that purpose, are as effectual as if made by the grantor and his heirs, and must be executed with the same formalities and recorded within fifteen days; neither is it necessary to set forth in the deed as a part of the title the proceedings which culminate in the decree of sale. Federal decisions as to the formalities necessary to the execution of a deed are apparently conflicting. This arises from the application of the principle that land or property must be governed by the law of the place in which it is situated, and the lack of uniformity of state laws upon this subject. The United States laws are applicable only to lands belonging to the United States and those located within the territories. See also CONVEYANCING, CONTRACT, CHARTER, TITLE-DEEDS, WILL, ERASURE, REGISTRATION, &c.

Deemster is the title of the two chief judges in the Isle of Man (q.v.). In Scotland, *Dempster* or *Doomster* was the name of an officer formerly attached to the High Court of Justiciary in Scotland, who pronounced the doom or sentence on

condemned persons. The office was held along with that of executioner. See Scott's notes to *Old Mortality* and *Heart of Midlothian*.

Deep-sea Exploration. See CHALLENGER EXPEDITION, and SEA.

Deer (*Cervidæ*), a large family in the ruminant section of even-toed Ungulates. Though doubtless of common ancestry, the antlered ruminants or deer are definitely, though not very readily, separated from the other great family of horned ruminants or cattle. The common characters of *Cervidæ* and *Bovidæ* will be noted under the title RUMINANT (q.v.); only the chief peculiarities of the *Cervidæ* need here be noticed.

General Characters.—If appendages are present on the head, they are true bony outgrowths, familiarly known as antlers. Except in one genus, they are confined to the males. There are two openings to the duct of the lachrymal gland, situated on or inside the orbit. A large cavity in front of the orbit cuts off the lachrymal bone from articulation with the nasals. The first molar tooth is short-crowned. There are usually upper canine teeth in both sexes, and these are often large in the males. In addition to the functional third and fourth digits, the second and fifth are very generally represented. The placenta has few cotyledons or villous patches. Except in Australia and Africa, the *Cervidæ* are distributed over the globe, usually living in pairs or herds in wooded and grassy regions, and feeding upon herbage. About 100 living and extinct species are known.

Genera.—Dr J. E. Gray classified the *Cervidæ* into two groups, according to the position of a hair-tuft on the lower part of the hind-leg. Professor Garrod has divided them according to features in the skull; Sir V. Brooke has classified them according to the state of the limbs. In their general outlines the three classifications agree; that of Brooke is here followed.

A. Upper ends of the second and fifth metacarpals remain—Plesiometa-carpi—e.g. *Cervus*. B. Lower ends of the metacarpals remain—Telemeta-carpi; within which the three genera *Alces*, *Hydropotes*, and *Capreolus* are separated by other characters from a more definite section, including *Cariacus*, *Pudua*, and *Rangifer*.

Important Forms.—As many of the important deer will be separately discussed under their common names, a list of the distinctive types is all that is here necessary. A. *Cervulus muntjac*, from British India and the Malayan region, with large canines in the males (see MUNTJAC); *Elaphodus*, with very small unbranched antlers; *Rusa*, a sub-genus of *Cervus*, from the Indian region, including some of the largest and smallest species—e.g. *C. aristotelis*, *C. equinus*; *Rucervus*, another Indian sub-genus, with forms of small stature—e.g. *C. schomburgki*; *Elaphurus*, *Axis* (q.v.), *Pseudaxis*, other sub-genera of *Cervus*; the genus *Cervus*, in the restricted sense, large deer in Palaearctic and Nearctic regions, including the Red Deer (q.v.), or *Cervus elaphus*, in Britain, Continental Europe, Algeria, Asia Minor, and the Caucasus, and *C. canadensis*, in North America; *Dama*, another sub-genus, including forms of medium size, from south-western Palaearctic regions—e.g. the Fallow-deer (q.v.), semi-domesticated in European parks. B. (1) The northern genus *Alces*, including the Elk (q.v.), of large size, with great antlers; the Water-deer (q.v.), or *Hydropotes*, without antlers in either sex; the genus *Capreolus*, including the small Roe-deer (q.v.) (*Capreolus caprea*), in Britain, Europe, North Palestine, &c. (2) The genus *Cariacus*, in its strict usage, including the Virginian Deer of the United States (*C. virginianus*) and the Mexican Deer (*C. Mexicanus*); the

sub-genera of *Cariacus*—*Blastocerus*, *Furcifer*, *Coassus*, from South America; *Pudua*, from the Chilian Andes; and the Reindeer (q.v.), or *Rangifer*, with antlers in both sexes.

Antlers.—Antlers are usually present in the male deer, though absent in both sexes in *Hydropotes*, and present in both in the reindeer. Their nature as true bony outgrowths, their early covering with sensitive vascular skin or velvet, the drying of this to leave the horn a hard and insensitive weapon, the basal constriction and detachment, and the regrowth in the following year, have been already referred to in the article ANTLER (q.v.). The different parts receive technical names, but it is only necessary to note the permanent 'pedicle' or stalk from which the regrowth starts, the main stem or 'beam,' the branches, 'tines,' or 'snags,' and the not infrequent flattened or 'palmate' form. Antlers are of special importance as weapons used by the males in fighting for the possession of the females, and have doubtless been perfected by Sexual Selection (q.v.). They are also of interest in the parallel they illustrate between the life-history of the individual and the evolution of the race. The figure given of antlers at successive years in a stag's life

will also suit for the evolution of antlers in successive historic periods. Young deer develop in the first year small simple antlers, and the branches are added on the annual regrowths. So the earliest (Lower Miocene) deer had no antlers, the Middle Miocene species had simple, at most two-branched processes, as in the second year of life, while in the Upper Miocene three branches occur; and in Pliocene and Pleistocene the modern luxuriance gradually appears. Sir V. Brooke gives full details (1) of the gradual evolution of antlers from very simple to complex forms, tracing the history from the earliest *Dremotherium* onwards; (2) of their constant tendency to vary, as is well known in the semi-domesticated species; (3) of 'variation extending far enough to induce the partial atrophy of one part of the antler to compensate for the extra development of some other part;' (4) of the transmission and establishing of such variations by heredity. A great part of the theory of evolution can be beautifully read from antlers alone.

Economic Importance.—The flesh, skin, and antlers of deer are important articles of human usage. The animals do considerable injury to crops, and eat the leaves, twigs, and bark of trees. They also damage forest trees by rubbing their antlers against the trunks and branches. See references above, and Sir V. Brooke in *Proc. Zool. Soc. London* (1878).

Deer, OLD, a village of Buchan, Aberdeenshire, 36 miles N. of Aberdeen. Here, about 580 A.D., St Columba (q.v.) and Drostan, his nephew, established a monastery, which William Comyn, Earl of Buchan, refounded about 1219 for Cistercian monks. Little remains of the monastic buildings; but in 1715 a Latin MS., a small octavo of 86 pages, which had belonged to the monks of Deer, found its way to the Cambridge University Library,

though not until 1860 was the attention of scholars directed to its great importance by Mr Bradshaw, the librarian. It contains St John's and parts of the other three gospels (in mainly the Vulgate version of St Jerome), the Apostles' Creed, and a fragment of an office for the visitation of the sick, with a Gaelic rubric. On the blank leaves of the MS., in the handwriting of the early part of the 12th century, are several Gaelic entries relating to the endowments of the Columban monastery. These notes are of the highest interest as the oldest specimens of Scottish Gaelic, and only less interesting is the Gaelic ornamentation enriching the MS. See Dr John Stuart's edition of the *Book of Deer* (Spalding Club, 1869), and Dr Joseph Anderson's *Scotland in Early Christian Times* (1881).

Deer-forests, tracts of country devoted to the red deer or fallow deer, either for sporting or for breeding purposes. The requisites of a Scotch deer-forest are a great extent of quiet ground, high mountain tops and corries, plenty of moorland and pasture. There is now little wood in Scotch deer-forests, and almost all other game, and cattle and sheep, must be excluded. One-tenth of the heather in a deer-forest should be burned every year, the heather living ten or twelve years; and in each forest a sanctuary should be provided. The forest of Mar is 80,000 acres in extent; Blackmount, 70,300; Reay, 64,600; then come fourteen of from 51,000 to 30,000; whilst the rest are smaller, some as low as 10,000 acres. The requisites of an English deer-park, on the other hand, are wood, lawn, with sufficient under-wood, rough grass and bracken, in an inclosed and undulating country of rich soil. In Scotland, deer-stalking has largely increased during the 19th century. In 1812 there were only five forests; in 1888 there were 111. In England, since 1750, when fox-hunting superseded deer-hunting, deer are kept chiefly for breeding and ornament, being sometimes fed in stalls. There are, however, several packs of staghounds which hunt the red deer—e.g. in the high ground of Somerset and Devon. Before the civil war there were 700 parks in England; now only 300, of which only 30 have red deer. Among the great Scotch forests may be noted: in *Aberdeenshire*, Ballochbuie, Mar, Glen Tanner, Glen Muick; in *Inverness-shire*, Abernethy and Glenmore, Rothiemurchus, Ben Alder, Gaick and Ruthven, Glen Feshie, Glen Strath Farrar, Guisachan, Invermarkie; in *Argyllshire*, Blackmount; in *Perthshire*, Athole, Fealar, Glen Bruar, Glen Artney, Rannoch; in *Ross-shire*, Dundonnell, Strathconan, Torridon, Kintail, Applecross, Wyvis, Diehidale, Kinlochewe, Morsgail, Kildermorie, Glen Carron, Park; in *Sutherlandshire*, Dunrobin, Glendhu, Loch Inver, Reay. The deer-forests of Scotland occupy a space of nearly 2,000,000 acres. They are occupied chiefly by English noblemen and others, not the owners. The best-known English parks are Eridge in Sussex, Talton in Worcestershire, Northwich in Cheshire, Duncombe in Yorkshire, Eastwell in Kent, Donington in Leicester, and the royal park of Windsor. Originally, in both England and Scotland, the king's nobles and the church held special forest jurisdictions of the most oppressive kind. Thus, in Scotland, the forester might forfeit cattle and other goods found within the forest. In England, the Norman lawyers pretended that all game belonged to the king. King John had 18 forests, 13 chases, 781 parks. A chase was an open forest, not subject to special forest law; a park was an inclosed chase on the land of the owner; a *purlieu* was an addition made to an old forest. The *Charta de Foresta* disafforested large tracts of land, and prevented the arbitrary creation of forests. In Scotland, the

Stewarts passed many statutes for the protection of deer, and so late as 1680, in the case of Faskally, the Court of Session recommended the king not to grant new forests, as hurtful to the lieges. In 1850 the Duke of Athole claimed a right to enter on the neighbouring estates to recover deer, but this was not permitted. It is the opinion of many that deer-forests have displaced crofters and sheep in the Scotch Highlands. This was denied by a Select Committee of the House of Commons, who reported on the Game Laws in 1872. Some dissatisfaction was expressed that deer-forests and other shootings were not entered in the Valuation Roll for purposes of assessment, unless they were actually let, and in 1887 an act was passed to remedy this. See *Manwood's Forest Laws*; *Shirley's Account of English Deer-parks* (1867); *Macdonald's Cattle, Sheep, and Deer* (1872); *Macrae's Hand-book of Deer-stalking* (Edin. 1880); the Report of the Crofters Commission (1884); and W. & A. K. Johnston's large map, showing all the deer-forests in Scotland (1888).

Deer Mouse (*Hesperomys*), often called Vesper Mouse, a genus of American rodents representing in the New World the Old-World mice, from which they differ only in trivial characters. The white-footed or deer mouse (*H. leucopus*) is found over the greater part of North America in several varieties. It is an animal about 3 inches in length, of a very variable but frequently fawn colour; sometimes arboreal, sometimes burrowing; feeding chiefly on corn and nuts, which it stores for winter. See MOUSE.

Deer-stealing. See GAME-LAWS, POACHING.

Deés, a town of Transylvania, on the Szamos, 37 miles NNE. of Klausenburg by rail. Pop. 6191.

Defamation. See LIBEL.

Default. A party to an action is in default when he fails to comply with the rules of procedure. If the defendant, for example, fails to appear to the writ, the plaintiff may have judgment against him; if the plaintiff fails to deliver a statement of claim, the defendant may apply to have the action dismissed. Judgment by default may be set aside, on such terms as to costs, &c. as the court thinks just. In Scotland, a decree by default may be recalled by reclaiming note, but after the time for reclaiming has expired, an action of reduction must be brought to set it aside.

Defeasance, DEED OF, in English law, an instrument which defeats the force or operation of some other deed or estate; and that which in the same deed is called a condition, in a separate deed is called a defeasance.

Defender of the Faith, a title conferred in 1521 on Henry VIII. by Pope Leo X. as a reward for writing his *Assertio septem Sacramentorum*, in answer to Luther. The title was afterwards confirmed by parliament (35 Henry VIII. chap. 3), and has ever since been used by the sovereigns of this country. The corresponding title in Spain is 'Most Catholic,' and in France was 'Most Christian King.'

Defenders, a Catholic association in Ireland (1784-98), the opponents of the Peep o' Day Boys.

Deffand, MARIE DE VICHY-CHAMROND, MARQUISE DU, one of the most brilliant letter-writers of the 18th century, was a member of a noble Burgundian house, and was born in 1697. She was educated in a convent in Paris, and as a girl became famous for her wit, audacity, and beauty. In 1718 she married the Marquis du Deffand, from whom she shortly afterwards separated. She led a life of gallantry for a number of years, and became a conspicuous figure in the literary society of Paris, her salon in the Rue Saint Dominique being a favourite resort of the *philosophes*. She was a correspondent

of Voltaire, Montesquieu, D'Alembert, and other great men of letters of her day. In 1753 she became blind, and in the following year she invited Mademoiselle de l'Espinasse to live with her and help her to preside over her salon. The arrangement lasted for ten years, when a quarrel broke out through Madame du Deffand's jealousy, and Mademoiselle de l'Espinasse departed, taking away with her D'Alembert and others of the elder lady's former admirers. From 1766 Madame du Deffand carried on an interesting correspondence with Horace Walpole, who held her in the highest estimation, and pressed the use of his purse on her when she fell into pecuniary troubles. 'To say nothing of her extraordinary parts,' Walpole wrote, 'she is certainly the most generous friendly being upon earth.' As a matter of fact, however, she was as selfish and spiteful as she was witty and shrewd. She died at Paris, September 24, 1780. See *Correspondance de Madame du Deffand* (new ed. 5 vols. 1865-67); her *Letters to Horace Walpole and Voltaire* (4 vols. Lond. 1810); and *Asse, Mlle. de l'Espinasse et la Marquise du Deffand* (1877).

Defilading, in Fortification (q.v.), consists in determining the direction and height of the rampart, so that the interior of the work may not be commanded by the fire of the enemy. To prevent the lines being entailed, their prolongations must avoid all places where hostile batteries could be posted, and the parapets must be of sufficient height to protect the interior from frontal fire.

Definite Proportions, LAWS OF, in Chemistry. See ATOMIC THEORY.

Definition, the process by which we determine the common qualities of the objects belonging to any given class, so as to distinguish effectively that class from other classes. Regarding the class as a species, we give the proximate genus and the difference; genus here denoting the distinctive qualities belonging to all of the genus, while the difference marks out the part of the genus in question. A good definition should state the essential attributes of the species defined, without containing the name itself, and should be exactly equal in denotation with it.

Deflagration is the term applied to the rapid combustion of ignited charcoal when a nitrate (such as nitrate of potash) or a chlorate (such as chlorate of potash) is thrown thereon. As chlorates do not occur naturally, it follows that deflagration with a natural salt indicates a nitrate; and if the deflagration be accompanied by a violet flame, it is characteristic of nitrate of potash (ordinary nitre or saltpetre); and if by a strong yellow flame, it is indicative of nitrate of soda (cubical nitre).

Deflection, in Navigation, the departure of a ship from her true course; in Optics, a deviation of the rays of light toward the surface of an opaque body.

Defluxion (Lat. *defluxio*), a discharge from a mucous membrane, especially of the air-passages, as in catarrh.

Defoe, DANIEL, immortal as the author of *Robinson Crusoe*, was born most likely in 1661, in the parish of St Giles, Cripplegate, London. His family belonged originally to Northamptonshire, and his father, James Foe, became a butcher in St Giles's, and was living so late as 1705. It was Daniel who first changed his name to De Foe, or Defoe, about 1703, for unknown reasons. He had a good education at a dissenting academy, but soon abandoned his early idea of becoming a dissenting minister, and engaged in business, apparently as a hose-factor, about the year 1685. Little is known of his early life. but it seems he was out with Mon-

mouth, and it is certain that he volunteered into King William's army in 1688, travelled both in France and Spain, and became bankrupt about 1692; his debts, or at least great part of them, he paid up later with a scrupulousness most honourable to him. He next became accountant to the glass-duty commissioners, and secretary to a Tilbury pantile factory. His *Essay upon Projects* appeared about 1698, and towards the close of William III.'s reign he became noted as an able and busy pamphleteer in support of the king's policy. His vigorous poem, *The True-born Englishman, a Satyr* (1701), was an attempt to apologise for the king's being a Dutchman by proving the English themselves to be a most composite race. His restless pen was active throughout the bitter struggle under Anne between the High-Church party and the dissenters, and his famous treatise, *The Shortest Way with the Dissenters* (1703), made him a martyr in the cause. Ostensibly written by a 'high-flyer,' it advocated the extirpation of dissenters with a masterly irony (pace Mr Saintsbury), which at first deceived and then infuriated his opponents, as, in his own words in *The Present State of Parties* (1712), it 'cut the throat of the whole party.' The House of Commons ordered the book to be burned, and a reward of £50 was offered for his apprehension, from which fortunately we have an exact description of his appearance as 'a middle-sized, spare man, about forty years old, of a brown complexion, and dark brown-coloured hair, but wears a wig; a hooked nose, a sharp chin, gray eyes, and a large mole near his mouth.' Tried at the Old Bailey in July, he was sentenced to pay a fine of 200 marks, to stand thrice in the pillory, and to be imprisoned during the queen's pleasure. Accordingly, the 'unabashed Defoe' stood in the pillory the last three days of July 1703, in the midst of a sympathetic mob that protected him from insult, and even drank his health. On the same day he suffered appeared his masculine *Hymn to the Pillory*, which concluded with a noble defiance to the government, expressed in some of his finest lines. During his imprisonment in Newgate he continued an incessant literary activity upon 'occasional conformity' and other points at issue in the great controversy, published a 'true collection' of his writings, and started his *Review* (19th February 1704—11th June 1713), at first a weekly, after eight numbers a bi-weekly, and after the eighth number of the second volume a tri-weekly newspaper, 'purged from the errors and partiality of newspapers and petty statesmen of all sides.' This was Defoe's largest, if not his most important work, and indeed forms one of the greatest monuments of literary industry ever reared by a single hand, embracing as it does in more than five thousand printed pages essays on almost every branch of human knowledge, and these written during but nine years, in which also, according to Mr Lee, he published no fewer than eighty distinct works, themselves containing as many as 4727 pages. Its 'Scandal Club,' which discussed minor matters of manners, was distinctly the forerunner of the more famous *Tatlers* and *Spectators*.

In August 1704 Defoe was released from prison at the instigation of Harley, who, moreover, procured for him pecuniary relief and employment, thus earning for himself the journalist's unceasing gratitude. After a short stay at Bury St Edmunds, he returned to London, maintaining at both places his activity in his *Review*, and in such admirable pamphlets as *Giving Alms no Charity*, and *Employing the Poor a Grievance to the Nation*, a masterly denunciation of indiscriminate charity and national workshops—a kind of socialistic scheme propounded by Sir Humphrey Mackworth. Next year (1705) appeared *The*

Consolidator; or Memoirs of Sundry Transactions from the World in the Moon, a political satire, which some have supposed may have supplied a hint for *Gulliver's Travels*; and the year after (5th July 1706) his masterpiece of verisimilitude and plausibility, *The True Relation of the Apparition of one Mrs Veal*. Mr Lee, in his life of Defoe (vol. i. pp. 127-8), disproves the old story that this fiction was a mere *tour de force*, written to sell an unsaleable book, Drelincourt on the *Fear of Death*, by showing that Drelincourt's book was already popular, being then rapidly running through its third English edition, while Defoe's pamphlet was only attached to its fourth edition by the author's consent. His next work was his *Jure Divino*, a tedious political satire, in twelve books of poor verse. About the close of 1705 Defoe was sent by Harley on a secret mission to the West of England, and in October of the next year we find him sent to Scotland by Godolphin, to whom Harley had recommended him as a secret agent to promote the Union, and here he lived for sixteen months. His *History of the Union* appeared in 1709, and in the same year Sacheverell's famous sermon gave him the opportunity of a fling at an old enemy. At the beginning of 1708 Harley's fall had made his political position somewhat precarious, but he found himself able to be a staunch Whig under Godolphin's government, until the fall of the Whigs after the error of Sacheverell's impeachment, and the return to power of his old benefactor Harley (1710), left him under the necessity of arguing that Englishmen should support the country even under a Tory ministry. In the pages of his *Review* he did his best to preserve the semblance of consistency, but not all his cleverness could save him from the contemporary reproach of being a time-server and a renegade. It is itself significant that his journalism was always anonymous from his second employment by Harley. He played a difficult and dubious part in the strange intrigues that preceded the accession of the House of Hanover, with the result that at length he found himself in a general discredit, which his apology, entitled *An Appeal to Honour and Justice* (1715), did not remove. Letters of his found in the State Paper Office in 1864, and printed in Mr Lee's introduction, revealed the fact that in 1718 he was in somewhat equivocal government service, subediting Jacobite and High Church organs, as the *Mercurius Politicus*, Dormer's *News-Letter*, and *Mist's Journal*, in such a dexterous way that 'the sting should be entirely taken out, although it was granted that the style should continue Tory' (second letter). Further, in the same letter he describes his purpose more fully, that these papers 'will be always kept (mistakes excepted) to pass as Tory Papers, and yet be disabled and enervated, so as to do no mischief, or give any Offence to the Government.' He describes himself further as 'for this Service, posted among Papists, Jacobites, and enraged High Tories—a generation who, I profess, my very Soul Abhors. . . . Thus I bow in the House of Rimmon.' Defoe was not exactly scrupulous in his point of honour, but it is certain he never was a Tory, and it would not be difficult for him to construct an argument by which he could persuade himself that by this dangerous and ambiguous means he was doing good service to the cause of liberty and religion.

Although Mr Lee maintains that he wrote busily in the journals almost to the close of his life, henceforward his interest for us is mainly literary. In 1715 appeared the first volume of the *Family Instructor*, and four years later the first volume of the immortal *Robinson Crusoe*, which at once leaped into that popularity which it will never cease to retain. The same year appeared the second volume, and the year after the greatly inferior sequel.

Defoe's realistic imagination worked most freely on a basis, however slight, of fact, and this was found for him in the four years' solitary residence of a marooned sailor, Alexander Selkirk, on the island of Juan Fernandez. Perhaps no man at fifty-eight in the whole history of literature ever devised a more splendid masterpiece of creative imagination than this marvellous story, which carries with it the irresistible conviction of very truth. In 1720—his most prolific year—he gave to the world the *Life and Adventures of Duncan Campbell*; the famous *Memoirs of a Cavalier*, the most real and truthful of all our historical romances, which the great Chatham accepted as genuine history; and *Captain Singleton*, a book of such brilliancy, vigour, and interest as would alone have given a reputation to any other writer. His next great creative year was 1722, in which he issued *The Fortunes and Misfortunes of Moll Flanders*, which is at least a marvel of the novelistic art; *The Journal of the Plague Year*, better known by the title in the second edition, *A History of the Plague*, a fresh masterpiece of verisimilitude and reality; and the *History of Colonel Jack*, which, though unequal throughout, and actually feeble towards its close, is in its commencement, and in episodes here and there, the most charming and, perhaps, the greatest of all his books. Later works were *Roxana, or the Fortunate Mistress* (1724), a weaker Moll Flanders; *A Tour through the Whole Island of Great Britain* (1724-26); *A New Voyage round the World* (1725); *The Complete English Tradesman* (1725-27), a glorification of mere money-getting, which Charles Lamb condemned for its 'vile and debasing tendency'; *The Political History of the Devil* (1726), which may be grouped with his *System of Magic* (1726) and *Essay on the Reality of Apparitions* (1727). The only other works that may here be mentioned are his *Religious Courtship* (1722), and *The Treatise concerning the Use and Abuse of the Marriage Bed* (1727), which reveal the strangely limited and vulgarly profit-and-loss character of his conception of religious duty. His *Everybody's Business is Nobody's Business* (1725) is an amusing diatribe upon the insolence of domestic servants—a subject to which he frequently recurs.

Meantime Defoe had been prospering in his affairs. He built himself 'a very handsome house' at Stoke-Newington, where he amused himself with gardening and the company of his three daughters. A mystery not yet satisfactorily explained hangs around his last days. His affairs seem to have fallen into confusion, one of his sons had behaved undutifully, and he was under apprehensions of some trouble, which may, however, have been due merely to a degree of mental derangement. He died 'of a lethargy' in Ropemakers' Alley, Moorfields, 26th April 1731, and was buried in Bunhill Fields.

Defoe remains one of our greatest English writers, and his greatness is of a kind unlikely to be disturbed by a competitor. His immense vitality and energy, clear-sightedness, and ready power of forcing plain arguments either in prose or verse to an irresistible conclusion, make him the typical journalist—to be surpassed only by Swift at his best; but it is to a much rarer quality than this that he owes his fame—his incomparable realism and faithfulness in fiction, the secret of which must be looked for not in his singularly plain and direct language, his simple-looking but most effectively artistic digressions, or his perfect though artless preservation of dramatic propriety, but in that subtle and impalpable genius which informs his style. For his character he was shifty, and perhaps somewhat low in his moral perceptions; but with all his political inconsistencies he remained true to the principles of the Revolution.

See the *Lives* by George Chalmers (1786), Walter Wilson (1830), William Chadwick (1859), and William Lee (1869); the studies by Scott, Lamb, Hazlitt, Forster, Leslie Stephen, and Professor Minto. The best approximations to complete editions of Defoe's works have been those of Scott and Hazlitt.

Deforcement, in English law, includes abatement, intrusion, disseisin, or any other wrong whereby he that has the right to a freehold is kept out of possession. 'Deforciant' was formerly the technical name of the defendant in the fictitious proceeding called a Fine. In Scotland, the term deforcement is most commonly used to denote forcible obstruction of the officers of the law: this is one of the cases in which the Court of Session has a criminal jurisdiction.

Deformities are variations in the form of the body as a whole, or in one or more of its parts, constituting a departure from the normal conditions of structure, and usually implying a corresponding divergence from natural and healthy functions. They may be divided into three groups, with reference to their origin—the *hereditary*, the *congenital*, and the *acquired*. The first group is characterised by a marked tendency to recurrence in the line of direct descent from generation to generation, as in those cases where the presence of extra fingers or toes has become characteristic of many members of one family (for a full record of an interesting case in point, see Carpenter's *Human Physiology*). Such hereditary tendencies to modification of form along certain lines of descent constitute local examples of the 'Natural Law of Variation,' which plays an important part in the Darwinian theory of the origin of species. According to this theory, modifications which are of value in the exigencies of the struggle for existence will become perpetuated, and supersede earlier and less favourable conditions of conformation; while modifications that do not possess such value, after repetition through one or two generations, disappear again, and these, since they are useless as well as aberrant conditions, are properly included within the group of *hereditary* deformities. In the second group, that of *congenital* deformities, occur those much more frequent abnormalities that result from disturbing influences acting on the otherwise normal embryo previous to its birth. These anomalies occur chiefly as deformities by defective development, and deformities by perverted development. Arrested development may be general, affecting the whole body, when a dwarf is produced; or local, affecting individual organs or parts, producing a great variety of obvious local deformities, in disproportion or malformation of special regions of the body. If the local arrest of development is absolute, the defect caused by it is so great as to constitute a *Monstrosity* (q.v.), where whole organs may be absent, as the brain (*anencephalia*), the skull (*acrania*), the lower jaw (*agnathia*), all the limbs (*amelus*), or one or more of them (*monobrachius*, *monopus*). Perverted development is seen in cases where parts normally separate become fused together, as in the 'siren-monster,' in which both lower limbs are welded into one tapering extremity. The causes producing these congenital monstrosities and the lesser and more common deformities of the same class are very varied and often very obscure. Modern writers have, however, made them a subject of special study under the name *Teratology* (*teras*, 'monster,' *logos*, 'science'), and have devised experimental conditions which illustrate the subject. Thus, in the case of the embryo chick, Panum found that deformities could be produced by varying the temperature of the hatching apparatus, and varnishing the egg shells; while Dareste discovered that a like result occurs if the eggs be placed vertically instead

of lying on their sides; and Gerlach, by varnishing the whole surface of the egg with the exception of a Y-shaped streak on one side, succeeded in producing a double-bodied chicken.

In the human subject the cause of the deformity may depend on purely mechanical conditions, as when the navel-string of the embryo becomes twisted round a limb and causes its gradual separation and destruction (so-called 'intra-uterine amputation'). In many cases, however, the cause is much more recondite, and appears to depend upon a variety of circumstances affecting the maternal organisation. In an increasing proportion of cases which are carefully investigated, it appears that maternal impressions, the result of shock or unpleasant experiences, may have a considerable influence in producing deformities in the offspring. This has for long been a popular theory, and it is one that recent scientific observation is tending to confirm, but only in a comparatively limited proportion of cases; and it must be admitted that the majority of cases cannot be explained on any theory of causation as yet suggested.

The chief varieties of malformation, coming under the heading of *congenital* deformities, are the following: (1) As regards the *number* of parts. In the *Siren*, two lower extremities are fused into one mass, but dissection shows that all the constituent bones of the limbs may be present, though much distorted, in the combined structure. In the *Cyclops*, the eyes are similarly fused into one irregular structure occupying the centre of the face. (2) As regards the *size* of parts. This may involve the whole body, as in dwarfs, of whom there have been some remarkable peripatetic specimens: the Corsican fairy was only 2 feet 7½ inches high; Mademoiselle Crachami, the smallest lady who ever lived, died at ten years of age, only 20 inches in height. This kind of deformity is not necessarily hereditary; the father of Borowalski, who was only 39 inches when thirty years old, had six children alternately short and tall; and dwarf women have brought forth infants as long, when extended, as their mothers. One limb only may be diminutive. Of course, deformities the opposite of these exist, such as giants, or instances of premature or excessive local growth. O'Byrne, the Irish giant, measured 8 feet 4 inches when he died at the age of twenty-two. Such individuals are generally subject to premature decay. One finger or one toe often grows to such abnormal dimensions as to necessitate its removal (local hypertrophy). (3) As regards the *shape* and *continuity* of parts. Distortion may occur from partial paralysis or irregular muscular action at an early stage of development, giving rise to Club-foot (q.v.), club-hand, &c.; or natural fissures or apertures which should close in the course of development may remain open, as in harelip, cleft palate, and *spina bifida*.

Acquired deformities arise in various ways as the result of injury or disease at any period after birth. Among injuries, burns, scalds, fractures, and dislocations are the most fertile causes of permanent deformity; and among diseases, rickets, and other diseases of bone, leprosy, and rheumatic affections are common causes. Another group of these affections, known as 'trade' deformities, are directly traceable to the special work done by the person suffering from them.

Defregger, FRANZ, painter, was born at Stronach, near Lienz, 30th April 1835. He studied under Piloty at Munich, and himself became a professor in the Munich Academy, the late King Louis conferring on him the Bavarian order of the Crown in 1883. The subjects of his pictures are almost all drawn from the everyday life or the history of his native Tyrol.

Degeneration, a biological term used to describe those not unfrequent cases where an entire organism falls below the structural level of its young stages, or where an organ in the same way loses its fullness of function, and becomes more or less atrophied, abortive, and simplified. Thus many parasitic worms, crustaceans, &c. are emphatically simpler than their free-swimming larvæ, and the sessile adult Ascidian shows only traces of the vertebrate characters which are plain enough in the active young. Thus, too, a crustacean which starts with a well-developed eye, may exhibit the gradual loss of this on assuming a dark habitat. The term is best confined to cases where a level of structure exhibited during early life is more or less lost in the adult. Degeneration must be distinguished (a) from occasional *abortion*, (b) from *Reversion* (q.v.) to an ancestral type, and (c) from the occurrence of *rudimentary and undeveloped organs* where a character possessed by ancestral types remains more or less undeveloped, or shows itself only in embryonic life. Degeneration may be due to the environment, or to cessation of function, or to some more subtle constitutional cause. Absence of food, heat, light, &c. may mean the absence of the necessary stimulus for the growth and maintenance of the organs, or superfluity of food may cause one system to preponderate over others. Nor can it be doubted that cessation of function checks the food-supply to a given organ, and in other ways helps to bring about its degeneration. But on the other hand, some less obvious cause—the fatigue of early life, a constitutional sluggishness, &c. may share in conditioning degeneration, as in the case of the majority of the Tunicata. Weismann and others, however, would explain degeneration by what they call the non-operation of natural selection. On this view, organs are not only developed but maintained by natural selection, and if it happen that an organ is no longer an advantage in this struggle for existence (e.g. eyes in dark caves), then natural selection no longer maintains that organ, and it disappears in the course of generations. Weismann applies this ultra-Darwinian conception especially to cases which might be called non-development rather than actual degeneration—e.g. to the slightly developed wings of the Apteryx. Most cases of degeneration properly so called appear hardly to require his subtle explanation, but find a sufficient one in the nature of the environment, in the effects of stopped function, and in the constitution of the organism. See Ray Lankester, *Degeneration* (Nature series, 1880); and Weismann, *Ueber den Rückschritt in der Natur* (Freiburg, 1887). See also, for instances, ASCIDIANS, CAVE-ANIMALS, CRUSTACEA, INSECTS, PARASITISM; also ENVIRONMENT, EVOLUTION, &c.

De Gérando, JOSEPH MARIE, BARON, author and philanthropist, was born 29th February 1772, at Lyons, France. His family was originally from Italy. In 1797 he went to Paris, but soon fled to Germany, where he entered the army of Massena as a common soldier. While with his regiment, De Gérando wrote a treatise, which was 'crowned' by the Academy, and which was afterwards enlarged and published under the title of *Des Signes et de l'Art de Penser* (1800). In 1802 appeared his *De la Génération des Connaissances Humaines*, a precursor of his *Histoire de Philosophie* (1803), long reputed the best French work on the subject. It procured him, in the following year, admission into the Academy. He was appointed secretary-general to the Ministry of the Interior by Napoleon. But De Gérando is even better known by his philanthropic writings. His excellent work, *Le Visiteur du Pauvre* (1820), obtained the Montyon prize, as did also his *Du Perfectionnement Moral* (1824).

De Gérando was elevated to the peerage in 1837, and died 12th November 1842, vice-president of the Council of State.

Deggendorf, a town of Lower Bavaria, on the Danube, which is here crossed by two bridges, 39 miles NW. of Passau by rail, with manufactures of paper, linen, woollens, stoneware, and matches. Its church of the Holy Sepulchre is often visited by more than 30,000 pilgrims annually. Pop. 6446.

Degraded, in Heraldry, means placed upon steps or degrees.

Degree, the 360th part of the circumference of a circle; see CIRCLE, GRADUATION. A degree of *latitude* is the length along a Meridian (q.v.), such that the difference of latitude between its north and south ends is one degree—i.e. from the two positions the altitude of the same star is seen to differ by one degree (see LATITUDE). Another definition is that two points on the earth's surface differ in latitude by one degree, when the verticals at these points make angles with the plane of the equator, differing by one degree. Were the earth perfectly spherical in shape, this distance along a meridian would be exactly equal to $\frac{1}{360}$ of the whole meridian, and would be the same at all parts of the earth's surface. But owing to its oblate spheroidal shape it increases from the equator, where the curvature is greater, to the poles, where it is less curved. From geodetical measurements made, it is found that at the equator the length of a degree of latitude is 362746.4 feet; while at the poles it is 366479.8 feet. The differences between the length of the degree of latitude in different latitudes, thus ascertained by actual measurement, is one of the proofs that the figure of the earth is not that of a sphere but that of an oblate ellipsoid.

A degree of *longitude* is the length between two meridians that make an angle of one degree at the poles, measured by the arc of a circle parallel to the equator passing between them. It is clear that this space is greatest at the equator, and vanishes at the poles; and it can be shown that it varies with the cosine of the angle of latitude. The annexed table shows the lengths of a degree of longitude for places at every degree of latitude from 0° to 90°. It is computed on the supposition that the earth is a sphere.

Degrees, UNIVERSITY. In its original signification a degree was simply a certificate that the person who held it was qualified to take part in the public teaching of a university. In the fully developed medieval university there were the four faculties of arts, law, medicine, and theology; and in each of these faculties there were special degrees of its own. These degrees were the baccalaureate, the licentiate, and the doctorate, though, strictly speaking, the first was not a degree, since it did not confer the right of public teaching. For the attainment of each degree certain subjects were prescribed for examination, as also a fixed term of study in connection with some university. Both the subjects and the periods of study varied with the progress of learning; but the different universities always sought to preserve a common standard. In Paris, at the close of the 15th century, the terms of study requisite to qualify for teaching in the different faculties were the following: in arts, four years; in law, seven; in medicine, eight; and in theology, fourteen. In modern times a degree in arts is simply a certificate of a certain measure of acquaintance with the subject to which it refers; but in the case of the higher faculties, that is, of law, medicine, and theology, the degree also implies a license to exercise the functions of the professions that depend on these faculties. It was formerly an indispensable condition to obtain a degree that the knowledge it represented should have been acquired at one or other of the legally constituted universities; but of late years certain universities, such as that of London, have been founded, which grant degrees to persons who pass examinations on prescribed subjects without the necessity of university attendance. A still further departure from the original import of the term is seen in what are known as 'honorary degrees.' Such degrees are conferred by universities on persons who have distinguished themselves in spheres of life which have no direct connection with the studies for which they exist. Thus, eminent soldiers, artists, and even merchants, have received the degree of Doctor of Laws. Not a few scholastic bodies are even understood to grant degrees on purchase, or on other such easy conditions that the original significance of the degree is completely lost. In the middle ages the right to confer degrees was granted by the pope, who was the recognised head of all the universities; and at the present day he claims the privilege of directly conferring degrees on whom he pleases. In Protestant countries the right can be granted only by the state. By an act of the reign of Henry VIII., the Archbishop of Canterbury received the right of conferring degrees; but these, known as 'Lambeth degrees,' never carried with them the same privileges as those of Oxford and Cambridge. In the medieval universities, music made part of the curriculum of the faculty of arts, and doctors and bachelors of music are still created by some universities. The German doctorate in philosophy corresponds in some respects to the M.A. degree elsewhere. The degrees of doctor and bachelor of science are of comparatively recent institution. For the usual abbreviations for degrees, see ABBREVIATIONS. See also UNIVERSITY, DOCTOR; and for the Chinese system of degrees, see CHINA, p. 190.—For degrees of relationship, see CONSANGUINITY.

De Gubernatis. See GUBERNATIS.

Dehiscence (Lat., 'gaping'), a technical term applied to the mode of opening of certain ripe fruits, those which do not open being termed *indehiscent*. See FRUIT.

Dehra, the capital of the Dehra Dún district in the North-western Provinces of India, is pleasantly

situated in a mountain-valley, 2300 feet above sea-level, and 100 miles N.E. of Meerut. Pop. (1881) 18,959.

Delaneira, daughter of Ceneus and Æthea, and sister of Meleager. She became the wife of Hercules, but unwittingly caused his death by sending him the mantle of the centaur Nessus, which was said to have the property of preserving love, but was really steeped in fatal poison. The poison entering his frame, the hero suffered such agony that he ordered a funeral pyre to be erected in Mount Ceta, and cast himself into the flames, whereupon Deianeira hanged herself from grief.

Dei Gratia (Lat., 'by the grace of God') is a formula taken from several apostolical expressions in the New Testament. It is believed to have been first formally used by the bishops at the Council of Ephesus, 431 A.D. Afterwards, it came to be appended by archbishops, bishops, abbots, monks, and even chaplains, to their titles, in letters, and other documents, as a humble expression of dependence on the Most High. After the middle of the 13th century, the higher clergy wrote *Dei et Apostolicæ sedis gratiâ*, 'by the favour of God and the apostolic see.' In the British Islands, this style was generally dropped about the time of the Reformation, but it was occasionally given to the Archbishops of Canterbury and York, even after the beginning of the 17th century. Many temporal princes, earls, and barons made use of the formula *Dei Gratia*; William II. and Edward III. of England employed it; and before the 15th century, no idea of independence or of divine right seems to have been attached to it. But in 1442 King Charles VII. of France forbade its use by the Comte d'Armagnac, and in 1449 obliged the Duke of Burgundy to declare that he used it without prejudice to the rights of the French crown. These instances show that it had now begun to be regarded as belonging exclusively to sovereigns who owed no allegiance to any other earthly potentate or power. In this way, what was originally a pious expression of humility came to be looked upon as an assertion of the doctrine of the 'divine right' of kings.

Deinotherium. See DINOTHERIUM.

Deipnosophists. See ATHENÆUS.

Deira, an ancient Anglian kingdom, extending from the Tees to the Humber, and westwards to the borders of Cumbria. With its northern neighbour, Bernicia, it was afterwards merged in the kingdom of Northumbria, but later both were earldoms under the West Saxon kings.

Deir-el-kamar ('convent of the moon'), a town of Syria, formerly the capital of the Druses, 13 miles SSE. of Beyrout. It is situated on the edge of a deep and picturesque glen of Mount Lebanon, on the opposite side of which stands the palace Bteddin, the summer residence of the Christian governor of Lebanon. Pop. 8000, mostly Maronites.

Deism properly means belief in a God, as opposed to atheism; but the term used to express this sense is *Theism* (q.v.). On the other hand, Deism is generally understood to imply the denial of a revelation; and a Deist is one who holds the existence and providence of God, but grounds his belief on reason and evidence, rejecting the testimony of a revelation. The name is often used vaguely by way of reproach.

The term Deists, or Freethinkers, is usually employed to designate a series of writers who appeared in England in the 17th and 18th centuries, and sought to establish Natural Religion upon the basis of reason and free inquiry, in opposition to all positive religions, and without reference to supernatural revelation. They were critical, if not hostile, in their attitude towards Scripture, and

denied miracles, the Trinity, and atonement by Christ; and they may fairly be taken as constituting one movement, though they by no means formed one school or agreed in the details of their teaching. Thus some believed and others rejected the immortality of the soul and human free-will, and they did not all teach the same doctrine as to the relation of God to the universe, some being almost pantheistic. They were not for the most part accurate scholars, and were rather acute than profound thinkers; but though their influence on English thought seemed for a time to be blotted out, they contributed largely to the progress of rationalism in Europe. The chief deists were Lord Herbert of Cherbury, called the 'Father of Deism' (died 1648), Blount, Tindal, Woolston, Toland, Lord Shaftesbury, Lord Bolingbroke, Collins, Morgan, and Chubb (died 1746). See the separate articles on these writers, also CHURCH HISTORY, RELIGION, RATIONALISM; Leland, *View of the Deistical Writers* (1754); Lechler, *Geschichte des Englischen Deismus* (1841); Hunt, *Religious Thought in England* (1872); Leslie Stephen, *History of English Thought in the Eighteenth Century* (1876).

Déjazet, PAULINE VIRGINIE, a great French actress, born at Paris, 30th August 1797. On the stage before she was five years old, she grew up playing children's and boys' rôles with marvellous precocity of intelligence and grace, but first awoke to a sense of her real greatness in an engagement at Lyons, where her playing of such parts as were then known as *soubrettes* endeared her to the citizens. In 1821 she began to play at the Gymnase, but her greatest triumphs were won at the Théâtre du Palais-Royal, whither she betook herself in 1834. From 1844 to 1849 she played at the Variétés, next at various Paris theatres, in the provinces, and at London, till 1859, when she undertook the management of the Folies-Dramatiques. She left the boards in 1868, next year received a pension of 2000 francs, and died 1st December 1875. See *Lives* by Lecomte (1866) and Duval (1876).

Dekker, THOMAS, dramatist, was born in London about 1570. He was a very prolific writer, but only a few of his plays were printed. In 1600 he published two comedies, *The Shoemaker's Holiday, or the Gentle Craft*, and *The Pleasant Comedy of Old Fortunatus*. The first of these pieces is one of the pleasantest of old plays, and the second abounds in poetry of rare beauty. Dekker's next play was *Satiromastix, or the untrussing of the Humorous Poet* (1602), in which Ben Jonson was held up to ridicule. In *Every Man out of His Humour* and *Cynthia's Revels* Jonson had made some satirical reflections on Dekker; and in *The Poetaster* (1601) he had assailed Dekker and Marston with bitter vehemence. Long afterwards, in 1619, Jonson told Drummond of Hawthornden that Dekker was a knave. Before the quarrel Jonson and Dekker had worked in harmony; in 1599 they wrote together two plays (which have not come down), *Page of Plymouth* and *Robert the Second*. In 1603 Dekker published a pamphlet entitled *The Wonderful Year*, which gives a heart-rending account of the sufferings caused by the plague. To the same year belongs the very amusing tract *The Bachelor's Banquet*, in which he describes with gusto the ills to which henpecked married men are forced to submit. His most powerful writing is seen in *The Honest Whore* (1604), of which the second part was published in 1630. Middleton assisted him in the first part. In 1607 he published three plays written in conjunction with Webster, the *Famous History of Sir Thomas Wyatt* (which has descended in a mutilated

state), *Westward Ho*, and *Northward Ho*. A pamphlet entitled *The Bellman of London* (1608) gives a very lively account of the vagabonds of London; and Dekker pursued the subject further in *Lanthorn and Candlelight* (1608), which passed through several editions. The most famous of his pamphlets is *The Gull's Hornbook* (1609), in which the life of a town-gallant is racily depicted. *The Roaring Girl* (1611) was partly written by Dekker; but Middleton must take the chief credit for that excellent comedy. From 1613 to 1616 Dekker was confined in the King's Bench prison. Earlier in his career he had spent some time in the Counter prison. In each case his debts were the cause of his imprisonment. With Massinger he composed the *Virgin Martyr*; and Lamb was doubtless right in ascribing to Dekker the most beautiful scene (II. i.) in that play. *The Sun's Darling*, licensed for the stage in 1624, but not printed until 1656, was written in conjunction with Ford. A powerful tragedy, *The Witch of Edmonton* (posthumously published in 1658), was written by Dekker, Ford, and Rowley. We hear of Dekker in 1637, when he republished his *Lanthorn and Candlelight* under the title of *English Villanies*, and then he drops out of notice. His plays were collected in 1873 (4 vols.); and his pamphlets, which afford much valuable information about English social life in the early 17th century, were republished in 5 vols. in Dr Grosart's 'Huth Library.'

De la Beche, SIR HENRY THOMAS, a well-known geologist, was born near London in 1796. He was educated at the military school at Great Marlow, and entered the army in 1814. Three years after, he became a Fellow of the Geological Society, of which he was afterwards made secretary, and eventually president in 1847. In 1820, while residing in Switzerland, he published a paper on the temperature and depth of the lake of Geneva. In 1824 he visited Jamaica, and published a paper on the geology of the island. Other works are a *Manual of Geology* (1831), *Researches in Theoretical Geology* (1834), and a *Geological Observer* (1853). He undertook to form a geological map of England; and soon after he had begun, the government, sympathising with his design, instituted the Geological Survey, and placed him at its head. He was founder of the Geological Museum in Jernyn Street, and of the School of Mines. In 1848 he received the honour of knighthood; and in 1853 was elected a corresponding member of the Academy of Sciences of Paris. He died 13th April 1855.

De la Borde, HENRY FRANÇOIS, COUNT, a French general, born at Dijon, 21st December 1764. The son of a baker, he enlisted at the outbreak of the Revolution, and by 1793 had risen to be general of brigade. He distinguished himself in Spain at the Bidassoa (1794), next commanded a division on the Rhine under Moreau, was governor of Lisbon in 1807, and was ennobled in 1808. He declared for the emperor on his return from Elba. He died 3d February 1830.

Delacroix, EUGÈNE, a French painter, chief of the Romantic school, was born at Charenton-Saint-Maurice, near Paris, 26th April 1799. At the age of eighteen he entered the *atelier* of Pierre Guérin, a follower of David, and came under the far more powerful influence of his fellow-pupil, Géricault. In 1822 he exhibited his first work, 'Dante and Virgil,' the novel force of which attracted much attention and won the praise of M. Thiers among others. In 1824, Delacroix, who was now at the head of the new school of young painters, produced the 'Massacre of Scio,' which was entirely repainted after the artist had studied a work of Constable's. The July revolution left its impress on Delacroix, and in 1831 appeared his

'Liberty directing the People on the Barricades.' In 1832 he made a voyage to Morocco, where he familiarised himself with novel effects of light and costumes. From this period, Delacroix continued to send forth picture after picture, besides decorating many public buildings and churches. He also executed a number of lithographs, including a series illustrating Hamlet, and one dealing with Faust, of which Goethe wrote that he found 'in these images all the impressions of his youth.' In 1837 he was chosen by the Institute to fill the place of Delaroche. He died August 13, 1863. The most striking quality of Delacroix's art is its invention, its impetuous imaginative force and vitality. He aimed at a powerful and dramatic expression of passion and emotion, and in the pursuit of this aim a sense of beauty was frequently lost. He was an admirable colourist, and his admirers have ranked him with Veronese and Rubens. His drawing, while sometimes incorrect, is always spirited and full of vigour. See his *Life and Letters* by Moreau (1873), Burty (1880), and Chesneau (1885).

Delagoa Bay, a Portuguese possession, is a large inlet of the Indian Ocean on the south-east coast of Africa. In April 1868 the Transvaal claimed by proclamation the Maputa River, from its junction with the Pongola to its embouchure into the southern part of Delagoa Bay. England and Portugal resisted the claim and set up counter pretensions. The matter was referred to the arbitration of Marshal MacMahon, who in 1875 declared the southern portion of Delagoa Bay, including the Maputa River up to the Lobombo Mountains, to belong to Portugal. The bay stretches for 70 miles between 26° 20' and 25° 30' S. lat. It is 25 miles wide, and for size and accommodation is the finest natural harbour in South Africa, although landing facilities are yet of a very primitive character. There are several islands, notably Inyack, and a number of shoals in the bay, but its navigation is safe and easy, and the anchorage is commodious and well sheltered. The settlement of Lourenço Marques and surrounding country have been notoriously unhealthy; but in 1887 the swamps behind the town were filled in, and in 1888 an elaborate system of drainage, and a long sea-wall, intended to reclaim the flat beach on which decaying vegetable matter was deposited, were projected. The rivers Maputa, Tembe, and Umbelosi (joining to form the English River), and the Komati, fall into Delagoa Bay. The Maputa and Tembe rivers are navigable for some distance for small craft. The comparative proximity of Delagoa Bay to the newly-developed gold-fields of Eastern Transvaal and Swaziland has brought to the front in South African politics the question of the desirability of Britain acquiring its possession by purchase. For over half a century there have been intermittent attempts to establish communication between the Transvaal and Delagoa Bay. All failed, however, till 1887, when a company with an authorised share capital of half a million was formed in London to work a concession from the Portuguese government for ninety years, for the construction of a railway from Delagoa Bay to the Transvaal frontier at the Komati Poort River. The line was partly opened in 1888, and great results are looked for as it is extended to the centres of population in the Transvaal. See LOURENÇO MARQUES.

Delambre, JEAN JOSEPH, astronomer, was born at Aniens, 29th September 1749, and studied literature under the poet Delille. He had long to struggle with difficulties, and supported himself by translation and teaching. Becoming a tutor in a wealthy family, he devoted himself to physics and astronomy, studying under Lalande. The discovery

of Uranus by Herschel in 1781 gave him the first opportunity of attracting the attention of the learned world in general by preparing tables of the motion of the new planet. Soon after, he commenced the construction of new solar tables, and tables of the motions of Jupiter and Saturn. Along with Méchain, he was appointed by the French government, in 1792, to measure the arc of the meridian between Dunkirk and Barcelona, which was completed in 1799 (see MÈTRE, ARAGO). He was elected member of the Academy, and in 1803 perpetual secretary of the mathematical section of the Institute. The result of his measurements appeared in his great work, *Base du Système Métrique Décimal* (1808-10). In 1807 he obtained the chair of Astronomy at the Collège de France, rendered vacant by the death of Lalande, his master and friend. In 1814 he was appointed a member of the Council of Public Instruction. He died at Paris, 19th August 1822. Delambre received a multitude of honours during his lifetime. He was a member of most of the learned bodies in Europe, and an officer of the Legion of Honour. His writings are very numerous. The principal are *Traité d'Astronomie* (1814), *Histoire de l'Astronomie Ancienne* (1817), *Histoire de l'Astronomie du Moyen Âge* (1819), *Histoire de l'Astronomie Moderne* (1821), and *Histoire de l'Astronomie au Dix-huitième Siècle* (1827). Besides these, Delambre wrote several excellent *Mémoires*.

Delane, JOHN THADEUS, editor of the *Times* newspaper, was the second son of a barrister, and was born in London, 11th October 1817. He received the earlier part of his education in private schools, and at King's College, London, and finally went to Magdalen Hall, Oxford, where he took his degree in 1839. At the university, he was more famous for horsemanship than reading, and though bright and active-minded, he never professed to be a scholar. After leaving Oxford he studied life in many forms, walked the hospitals, was called to the bar, and reported in the House of Commons and on circuit. Mr Walter had early marked Delane's capable character, and soon placed him on the *Times* staff; and in May 1841, not yet twenty-four, he became its editor. For thirty-six years Delane held this post, aided, however, for the greater part of this period by his brother-in-law and college friend, George Daseant (q.v.). Under his editorship, the *Times* attained a prodigious circulation, and an influence unparalleled in the history of journalism. He wrote no articles, but he contributed excellent reports and letters. He merged his personality in his paper, and the history of his later life is the history of the extraordinary influence wielded by the leading journal. His exposure of the railway mania, his vehement attacks upon the management of the Crimean war, and his strong opposition to England's assisting Denmark in 1864, are among his best-remembered acts. He was singularly shrewd in weighing public opinion, possessed remarkable foresight, and seldom made a mistake. Having resigned the editorship in 1877, he died two years later, 22d November 1879. His successor was Thomas Chenery. A *Life of Delane* by Sir G. Daseant was announced, but abandoned in deference to Mr Walter.

Delany, MRS (Mary Granville), was born at Coulston, Wiltshire, 14th May 1700. The niece of Lord Lansdowne, she married first, in 1718, 'fat, snuffy, sulky' Alexander Pendarves (1659-1724); and secondly, in 1743, the Rev. Patrick Delany (1685-1768), an Irish divine, Swift's friend, and the author of a dozen volumes. After his death she lived chiefly in London, till her own death at Windsor on 15th April 1788. Her much-admired 'paper mosaics,' or flower-work, have long since

faded; but she is remembered through her patronage of Miss Burney, and by her *Autobiography and Correspondence* (6 vols. 1861-62), with its gossip of the court and the literary society of her day.

De la Ramée, LOUISA. See OUIDA.

Delaroche, HIPPOLYTE, known as PAUL, painter, the head of the modern Eclectic school of art in France, was born at Paris, 16th July 1797. He studied under Baron Gros, and between 1819 and 1823 acquired some note by painting scriptural subjects, but first excited public admiration in 1824, by his 'St Vincent de Paul preaching in the Presence of Louis XIII,' and 'Joan of Arc before Cardinal Beaufort.' These exhibit the earliest indications of that style for which he afterwards became famous—a style which endeavoured to unite the picturesqueness of the romantic with the dignity of the classic school of art. In 1826 Delaroche produced his 'Death of President Durante;' and in 1827 his 'Death of Queen Elizabeth.' These pictures greatly increased his reputation, but the last is reckoned a failure by English critics. In 1831 he produced the 'Princes in the Tower,' a work of high merit; in 1833, 'Cromwell contemplating the Corpse of Charles I,' which is generally regarded as one of the first historical paintings of modern times. In 1834 appeared his 'Execution of Lady Jane Grey;' and in 1837 his 'Charles I. insulted by the Parliamentary Soldiers,' and his 'Strafford receiving Laud's Blessing on the Way to Execution.' From this period until 1841 he was engaged on what is probably his grandest work—the series of paintings on the wall of the semicircular saloon of the École des Beaux Arts, in the execution of which he was aided by Armitage and other of his pupils. This composition, in which the style is simple, lofty, and chaste, contains 74 figures, comprising the greatest sculptors, painters, and architects in all history, according to Delaroche's judgment. It was excellently engraved by Henriquel Dupont, from a reduced copy made by the painter himself. Among his later works may be mentioned, 'Bonaparte at St Bernard' (1850); 'Marie Antoinette before the Revolutionary Tribunal' (1851); 'The Finding of Moses' (1852); 'Calvary' (1853); 'Christ in Gethsemane' (1854); 'The Girondins in the Concierge' (1856); and, one of his best-known works, 'The Floating Martyr.' He also executed some striking portraits, including those of M. Guizot (1838), and M. Thiers (1856). He died November 4, 1856. The characteristic excellences of Delaroche are picturesqueness of conception, precision of handling, and accuracy of drawing. He has been accused, however, of want of fire, imagination, and depth, and it must be admitted that he very rarely, if ever, exhibits the highest qualities of creative genius. Delaroche was made a member of the Institute in 1832, and professor of Painting in the École des Beaux Arts in 1833. See Rees, *Vernet and Delaroche* (1880).

De la Rue, WARREN, an eminent electrician, was born in the island of Guernsey, January 18, 1815. He was educated at Paris, and early entered his father's business—the manufacture of paper-ware—for which his inventive ability and scientific knowledge enabled him to devise many new machines and processes. He took an active part in the Exhibitions of 1851 and 1862; was a member of the International Electrical Congress at Paris in 1861; and has been president of the Royal Astronomical Society, of the Chemical Society, and the London Institution. In 1878 he succeeded Spottiswoode as secretary of the Royal Institution, and in 1880 was elected a corresponding member of the French Académie des Sciences in the department of astronomy. His scientific work, done at his observatory at Cranford and at his private physical labor-

atory, is of the highest value in the departments of astronomical photography and electricity, and its results have been communicated from time to time to the Royal Society and the French Académie des Sciences.

Delaunay, LOUIS ARSENE, a French actor, was born 21st March 1826, at Paris, and made his début in October 1846 at the Odéon. In the year 1848 he first trod the classic boards of the Théâtre Français in the rôle of Durante, and here he soon procured an engagement and became secretary to the theatre in 1850. Delaunay is one of the most accomplished actors on the French stage. He has found some of his greatest parts in the plays of Hugo, Pailleron, De Musset, and Augiers.

Delavigne, JEAN FRANÇOIS CASIMIR, dramatist, satirist, and lyrist, was born at Le Havre on April 4, 1793. He became one of the most popular writers in France, after the publication in 1818 of his *Messéniennes*, satires directed against the monarchy of the Restoration. He then turned his attention to dramatic authorship and produced *Les Vêpres Siciliennes* (1819), a tragic piece, which was followed by the comedies, *L'École des Vieillards* and *Les Comédiens* (1821). He was made an academicien in 1825. As a lyrist and satirist, he espoused the cause of the patriots in Italy, Greece, and Poland, and of the democratic party in France, but although he appears to have been a sincere politician, he failed to give natural and original expression to his convictions. His tragedy of *Louis XI.*, which was partly founded on *Quentin Durward*, and an adaptation of which is familiar to English playgoers, was brought out in 1833. Among his other dramas were *Le Paria*, *Marino Faliero*, *Les Enfants d'Edouard*, *Don Juan d'Autriche* (1835), and *La Fille du Cid* (1839). He died on December 11, 1843. He had no true poetic faculty; neither was he a skilful dramatist, though his plays, when first produced, gained considerable popularity. In his day he was supported by the opponents of the Romantic school, but his mediocrity has come to be recognised by critics of all parties.

Delaware, one of the Atlantic States of the American Union, forms a part of a peninsula lying between the lower reaches of the Copyright 1889 in U.S. by J. B. Lippincott Company.
Susquehanna and Chesapeake Bay on the west, and the Delaware River and Bay and Atlantic Ocean on the east. The state is bounded on the N. by Pennsylvania (the boundary there being an arc of a circle), on the E. by the Delaware River and Bay and the Atlantic Ocean, and on the S. and W. by Maryland. With an area of 2050 sq. m., or little more than that of Northumberland, it is the smallest of all the states, except Rhode Island; in 1880 it was the smallest of all in population, except Nevada. Save in a small hilly section in the north, nearly all the surface is low and level, and in the extreme south there is much swampy land; while the most southern two-fifths of the area is in great part a sandy region. The hill-district in the north presents a stony surface overlying azoic rocks, such as gneiss and granite, with patches of serpentine and limestone. A strip of highly fertile red clay lies south of the hill-country; and next southward occurs a productive and fossiliferous greensand formation, succeeded by a somewhat sandy belt, less fertile than the greensand, although the greater part of its extent is by no means unproductive. The coast-region has many salt-marshes, some of them dyked, and thus rendered tillable; and farther inland is a considerable body of extremely rich alluvial soil. The western border of the state is generally well wooded, and in some places flat and marshy. The rivers of Delaware are mostly small,

but many are navigable. In the north kaolin and iron ore are found, and bog ore or limonite occurs to some extent in other parts. The state is divided into three counties, New Castle in the north, Kent in the centre, and Sussex in the south.

The state is well provided with railroad facilities, and is crossed by a canal connecting the Delaware and Chesapeake bays. The northern section has large and varied manufacturing interests. Fishing and the taking of oysters and crabs are important industries in Sussex county, and along the shores and tidal streams. Peaches and the various small fruits, as well as market-garden products, are leading articles of export; the principal cereal crops are maize, wheat, and oats. Pop. (1870) 125,015; (1880) 146,608, of whom 26,448 were of pure or mixed African descent. The principal towns are Wilmington (pop. in 1880, 42,478), New Castle (3700), Dover, the state capital (2811), and Smyrna (2423).

Delaware's first permanent white settlements were made by Swedes and Finns who settled at Christina (Wilmington) in 1638; for a Dutch settlement of 1613 at Hoornkill (now Lewes) was destroyed a year later by the Indians. The colony of New Sweden included a small part of Pennsylvania and a section of New Jersey. For several years the Dutch and Swedes contended for the possession of this region, till in 1655 it passed under Dutch sway. After the transfer of New Amsterdam (now New York) to the English rule in 1664, Delaware, like the stronger colony, became English also. It was governed from New York until 1682, when William Penn became proprietary of the three Delaware counties, which, however, were never considered as forming any part of Pennsylvania, to which colony they were attached. In 1776 a constitution was adopted, which was set aside by another in 1791; and this was revised in 1831. Delaware was a slave-state until the war of 1861-65, but took no part in the secession movement. It offers several curious survivals, such as its division into hundreds, and the retention of whipping-post and pillory.

Delaware, THOMAS WEST, LORD, the first governor of Virginia, arrived there from England in June 1610, but nine months later was prostrated by ill-health, and died in 1618.

Delawares. See AMERICAN INDIANS.

Del Credere Commission, the higher rate or allowance charged by a factor or agent, in respect of which he guarantees the solvency of the purchaser, and renders himself personally liable to his principal in case of the purchaser's failure to pay the price of the goods sold. It is not necessary that the contract be in writing. The amount of the premium is of course variable, but it is frequently double an ordinary selling commission.

Deleb Palm, or ETHIOPIAN FAN-PALM (*Borassus ethiopicum*), is very common and widely distributed throughout Central Africa, where it often practically replaces the date palm in the domestic economy of many negro tribes. Its large hard nut is eaten fresh, but also largely planted until germination has fairly commenced; the young embryo thus laden with sugar, &c., is then eaten raw or cooked. See GERMINATION, and MALTING.

Delectus (Lat., 'a selection'), the old name often applied to a selection of passages from Latin or Greek writers graduated in difficulty for the use of young learners. None is so famous as Valpy's.

Delegation (Ital. *delegazione*), the term formerly applied in Lombardy, Venice, and the States of the Church, both to the governor and governing court of a province and to the province itself. The

number of such provinces varied, but was at one time nineteen. The delegate was always a prelate, and directly appointed by the pope. If he was a cardinal, he was called a Legate, and his province a Legation.

Delescluze, LOUIS CHARLES, French communist, was born at Dreux, 20th October 1809. His politics early drove him from France to journalism in Belgium, but the February revolution opened to him a career in Paris, where his clever and facile pen quickly made him popular with the rabble, but earned him from the authorities imprisonment and a fine of 10,000 francs. Again at Paris in 1853, he was sentenced to two years' imprisonment, and was next transported to Cayenne, where he remained till 1859. His experiences of his sufferings he gave in *De Paris à Cayenne; Journal d'un Transporté* (1867). After his return he was quiet for some years, until his journal, *Réveil*, started in 1868 to advocate the doctrines of the International, brought him anew into trouble. In the infamous history of the Paris Commune he played a prominent part, and upon his head rests in great part the guilt of its most execrable atrocities—the murder of the hostages, and the burning of the public buildings of the city. He died on the last barricade, 28th May 1871.

Delfshaven, an old town in South Holland on the Maas, 1½ mile W. of Rotterdam, with shipping and some manufactures. Pop. (1880) 11,425.

Delft, one of the most ancient towns of South Holland, is situated on the Schie, 8 miles NW. of Rotterdam by rail, and is intersected by numerous canals. Delft was noted from the 16th to the 18th century for its delft-ware (see POTTERY), but has now entirely lost its high reputation for this manufacture, and not more than a few dozen persons are engaged in making earthenware. Of several interesting buildings, one, the town-hall (1618), is a picturesque and richly adorned edifice. The New Church (1476) contains a monument, more ornate than tasteful, to the memory of William I. of Orange, who was assassinated here, 10th July 1584. It also contains the tomb of Grotius, and the burial-vaults of the present royal family of Holland. The Old Church, a building of some note, contains the tomb of the naturalist, Leeuwenhoek, and of the great admiral, Van Tromp. Delft has also a state arsenal, an East Indian college, a polytechnic, and several hospitals. There are some manufactures of fine carpets, casks, baskets. Pop. (1876) 23,804; (1888) 27,591.

Delhi (*Dehli*), an imperial city of Northern India, and the chief commercial and industrial centre of the Punjab, on the right bank of the Jumna, 13 miles from the railway junction of Ghaziabad, 113 NNW. of Agra, and 954 NW. of Calcutta. It is walled on three sides, has ten gates, and stands on high ground, the grand series of buildings forming the famous palace of Shah Jehan, now the Fort, looking out over the river and a wide stretch of wooded and cultivated country. To the north, about a mile distant, rises the historic 'ridge,' crowned with memorials of the Mutiny, and commanding a fine view of the city, the domes and minarets of which overtop the encircling groves. The gardens in the city, the suburbs, and the neighbouring country, are all richly wooded. Delhi is the terminus of the East Indian and Rajputana railways, the former crossing the Jumna by a fine iron bridge. Fergusson describes in detail the palace buildings, which are the splendid heritage of Mogul sovereignty. Briefly, they comprise the cathedral-like entrance hall, the *diwan-i-khas*, or audience hall, the *diwan-i-am*, the *rang mahal* (now a mess-room), and several lesser pavilions,

covering in all an area of 1600 feet by 3200, exclusive of gateways. The beautiful inlaid work and carving of these buildings are the admiration of the world, and the *diwan-i-khas* is worthy of its famous inscription: 'If there is a heaven on earth, it is this—it is this!' In the heart of the city stands the Jama Masjid ('great mosque'), one of the largest and finest structures of the kind in India, which also owes its origin to Shah Jehan. Among the notable monuments in the neighbourhood are the imperial tombs, including that of Humayun, second of the Mogul dynasty; the old Kala Masjid, or black mosque; and the famous Kutab Minar, 10 miles to the south. The Minar, erected by Kutab-ud-din, founder of a dynasty, early in the 13th century, is 238 feet high, and tapers gracefully from a diameter of 47 feet at the base to 9 feet at the summit. It incloses a winding staircase, and is garlanded with inscriptions from the Koran. Modern Delhi is noted for its broad main streets, the chief being the Chandni Chauk, or Silver Street, with its high clock-tower, and the institute and museum. The Delhi College, once a famous oriental school, has been abolished, government having withdrawn the collegiate staff of teachers to concentrate the grant upon the central institution at Lahore. Delhi has a large trade in wheat and other produce, and its bazaars are noted for gold and silver work, precious stones, shawls, and costly fabrics. It is a great native banking centre. Across the river is the ruined fort of Salimgarh, and traces of an ancient city. Pop. (1888) 185,000, more than half Hindus.

The name Dilli or Dillipur first appears in 1st century B.C., and is connected with the famous iron pillar of Raja Dhava, a solid shaft of metal, set up in the 3d or 4th century, which is 16 inches in diameter, and 50 feet long, and which is so firmly planted that only half of it is above ground. This indisputable relic bears a Sanskrit inscription, in which the name of the city is mentioned. Delhi was the capital of the Afghan or Pathan, and afterwards of the Mogul empire. It was taken by a British army under Lord Lake, September 8, 1803, and has ever since—if we except the brief period when it was held by the mutineers in 1857—continued under British rule. In our own time, Delhi has been rendered memorable by the events of 1857. The march on the city of the mutineers from Meerut; the terrible 11th of May; the explosion of the powder-magazine by Willoughby and his heroic band; the assault, when the city was won (September 20) gate by gate and quarter by quarter—a success saddened by the death of the gallant Nicholson; the subsequent daring capture of the king of Delhi by Hodson of Hodson's Horse; and the capture and shooting of his miscreant sons by the same officer, are memorable events in Indian history. A memorial to Willoughby was erected by government in 1888. In 1877 Delhi was the scene of the famous Durbār at which the Queen was proclaimed Empress of India. Delhi is now the most Europeanised of all the cities in the interior of India, and the removal of some of the old gates was among the improvements contemplated in 1888.—The district has an area of 1277 sq. m., and a pop. of 643,515. The trade and manufactures of the district centre in the town of Delhi. There is a branch of the East Indian Railway, and the Rajputana State Railway traverses the district for about 13 miles. Of about 820 sq. m. under cultivation, over a sixth are irrigated from government canals, and a smaller part by private enterprise. To the south, the district is rocky and barren. The soil along the alluvial margin of the Jumna is fertile, but better crops are produced in the tract artificially irrigated by the Western Jumna Canal.—The division of Delhi

comprises the three districts of Delhi, Gurgaon, and Karnal, with an area of 5610 sq. m., and a pop. (1881) of 1,907,984, 72 per cent. of whom were Hindus.

Delibes, LÉON, a French composer, born in 1836 at St Germain du Val, in the Sarthe, entered the Paris Conservatoire in 1848, and in 1855 produced an operetta, *Deux Sacs de Charbon*. At the Grand Opéra, where he became second director in 1865, his music for the ballet *La Source* (1866) met with great success, and his ballet-music for *Coppélia* (1870), his finest work, secured his position as a composer. He has written music for a third ballet and for three comic operas, one of which, *Le Roi l'a dit* (1873), became very popular. In 1880 Delibes was appointed professor of Composition in the Conservatoire.

Dell'lah (signifying, according to Bertheau, 'the delicate'; according to Ewald, 'the traitress'), the Philistine woman who betrayed Samson (q.v.).

Delille, JACQUES, a writer extravagantly overrated in his lifetime, was born near Aigues-Perse in Auvergne, on June 22, 1738. He was an illegitimate child, and was brought up by charity. Educated at the Collège de Lisieux in Paris, he distinguished himself as a scholar, and obtained a professorship in Amiens. His verse translation of the *Georgics*, published in 1769, had an extraordinary vogue, and was extolled far beyond its merits by Voltaire and other critics. Its author was made an academicien in 1774, and, after holding a canonry at Moissac, was presented by the Comte d'Artois with the abbacy of Saint-Severin, the income of which amounted to 30,000 livres a year. *Les Jardins*, a didactic poem which Delille published in 1782, found a vast body of readers, and was generally accepted as a masterpiece. The outbreak of the Revolution compelling Delille to leave France, he travelled in Switzerland and Germany, and then removed to London, where he occupied himself for eighteen months in translating the *Paradise Lost*. After his return to France in 1802, he produced a translation of the *Æneid* (1804) and several didactic and descriptive works in verse—*L'Imagination* (1806), *Les Trois Règles* (1809), and *La Conversation* (1812). He became blind in his old age, and died on May 1, 1813. During his life he was not only regarded by his countrymen as the greatest French poet of the day, but was even declared to be the equal of Virgil and Homer. His fame, however, suffered a rapid eclipse, and his lack of poetic genius is now generally admitted. He was merely a fluent versifier, whose knack of turning out ingenious paraphrases exactly suited the taste of his contemporaries. See Sainte-Beuve's *Portraits Littéraires*, vol. ii.

Deliquescence is the term applied to the property which certain substances have of absorbing moisture from the air, and becoming damp, and even running into liquid. Caustic potash, and the chlorides of calcium and magnesium, are examples of substances which undergo this change.

Delirium is a condition in which there is perversion of the mental processes. In its essential nature this symptom is analogous to insanity; insanity is, in short, a similar state, unaccompanied by the obvious conditions which are the causes of delirium.

In health the mental processes correspond to present sensory impressions or to the memory of those which are past, but in delirium this correspondence ceases, and the results of cerebral activity bear no true relation to reality. Delirium has three well-known mental phenomena, any or all of which may be present in any indi-

vidual instance. The mind may be possessed by false ideas or *delusions*; sensory impressions may produce false perceptions or *illusions*: or there may be fictitious perceptions or *hallucinations*, without the presence of any sensory impressions.

The more common causes of delirium are four. (1) Local diseases of the brain or its envelopes, as in the case of inflammation of the lining membranes. (2) Toxic substances circulating in the blood, which may have their origin within the system, as in the retention of waste products during the final stages of kidney disease, or may be introduced from without, such as the specific poisons of the acute infectious diseases, or active substances like alcohol. (3) High body temperatures, which may occur apart from any blood-poison in a local inflammation of some distant organ. (4) Inanition, which may often be seen in the concluding periods of wasting diseases.

Delirium Tremens is the term employed to denote one of the acute phases arising in the course of chronic Alcoholism (q.v.). It is as a rule precipitated by a period of indulgence in excessive drinking, and shows itself at first in the form of general uneasiness and restlessness during the day, followed by sleeplessness, or disturbed sleep with distressing dreams, at night. These initial symptoms usher in the stage of delirium, always accompanied by constant muscular tremors. The delirium almost invariably presents the three main varieties of mental disturbance—illusions, hallucinations, and delusions—to which reference has been made in the preceding article. An attack generally lasts about three days, but it may exist for a period of six or seven days, and, so far as is at present known, there is no means of shortening its duration. The chief danger lies in the great tendency to exhaustion which the disease shows. One attack appears to have a power of predisposing the individual who has suffered from it to subsequent recurrence. The affection frequently induces some degree of mental weakness, and this is more likely to be the case in those who belong to families which have a hereditary tendency to insanity. As above mentioned, no means is known of cutting short an attack, and the employment of drugs in this disease is of at least doubtful utility. The only rational treatment consists in the use of every expedient which can tend to sustain the patient, and avert the great tendency to exhaustion of the vital centres.

De Lisle. See ROUGET DE LISLE.

Delitzsch, a town of Prussian Saxony, on the Lösser, 12 miles N. of Leipzig by rail, with manufactures of cigars, straw, leather, ivory, and wooden goods. Pop. 8342.

Delitzsch, FRANZ, a learned theologian and Hebraist, born at Leipzig, February 23, 1813, studied theology and orientalia at the university there, and became professor of Theology at Rostock in 1846, whence he was called to Erlangen in 1850, and to Leipzig in 1867. Delitzsch's vast learning and exegetical sagacity combined to give him a foremost place among the more conservative German theologians, while his great personal influence over a generation of Leipzig students, and a long series of profoundly learned books, contributed enormously to extend a sound knowledge of Old Testament exegesis not only in Germany, but in England and America. His earliest works were in the field of the post-biblical Jewish literature, followed by his commentaries on Habakkuk, Song of Solomon, Genesis, the Psalms; and to the complete commentary on the Old Testament, edited jointly with Keil, Delitzsch himself contributed the volumes devoted to Isaiah, Job, Solomon's Proverbs, Canticles, and Ecclesiastes. Later

works are his *System der biblischen Psychologie* (1855), *System der christ. Apologetik* (1869), *Jesus und Hillel* (1867), *Jüd. Handwerkerleben zur Zeit Jesu* (1868), and a few books of edification. His new commentary on Genesis (1887) marked a large concession to the modern critical theory of the Pentateuch.—His son, FRIEDRICH DELITZSCH, born 3d September 1850, has already made a great reputation as an Assyriologist by his *Assyr. Studien* (1874), his translation of George Smith's *Chaldean Account of Genesis* (1876), his *Assyr. Lesestücke* (1878), *Wo lag das Paradies?* (1881), and his great *Assyr. Wörterbuch* (1887 et seq.).

Delius, NIKOLAUS, a distinguished German Shakespearian critic, was born at Bremen, 19th September 1813, and studied philology at Bonn and Berlin, and in England and France. He finally settled in 1846 at Bonn, where he became extraordinary professor in 1855, and professor in 1863, and where he died 18th November 1888. His early lectures were on Sanskrit and the Romance tongues, but he afterwards devoted himself to the English language and literature, and as a student of Shakespeare took a place that, in the opinion of most scholars, was second to none. Apart from excursions of lesser importance in other fields of literature, he published *Abhandlungen zu Shakespeare* (1878), &c.; and his edition of Shakespeare's works (Elberfeld, 7 vols. 1854-61; 5th ed. 2 vols. 1882) is an acknowledged masterpiece, its notes a marvel of terse sagacity.

Delivery of a Deed. See DEED.

Della Cruscan School. About the year 1785, a number of English residents at Florence endeavoured to amuse their lagging hours by writing verses, which they published under the title of *The Florence Miscellany*. The insipidity, affectation, and fantastic silliness of these productions transcend belief; yet such was the poetic poverty of the time, that they soon found a crowd of admirers and imitators. Taking the name of a Florentine Academy (q.v.), the Della Cruscan now began to print their precious lucubrations in England, chiefly in two daily newspapers called the *World* and the *Oracle*. 'While the epidemic malady was spreading from fool to fool,' as Gifford pungently says, one of the brotherhood, a Mr Robert Merry, came over from Florence, and 'immediately announced himself by a sonnet to Love.' It was answered by one, 'Anna Matilda' (Mrs Cowley), who (as was the custom) praised it immoderately in language even more absurd than Merry's own. 'The fever now turned to a frenzy: Laura, Maria, Carlos, Orlando, Adelaide, and a thousand other nameless names, caught the infection; and from one end of the kingdom to the other all was nonsense and Della Crusca.' But retribution followed, for Nemesis watches the course of poetry as sharply as that of politics. In 1794 Gifford produced his *Baviad*, and in 1796 his *Mueviad*. Rarely has literature witnessed such a scalping. It completely killed the school, and, indeed, it is only in these two poems that the memory of most of the unhappy Della Cruscan songsters has been preserved—an immortality which may be compared with that conferred by the *Newgate Calendar*.

Dellys, a port of Algeria, 50 miles E. of Algiers, with a French garrison. Pop. 3564.

De Lolme, JOHN LOUIS, born at Geneva in 1740, was originally an advocate in his native town, but about 1769 came to England, where, in spite of his literary activity, he lived for several years in great poverty, always in debt and repeatedly in prison. Having inherited a small

property, he returned to his native country in 1775, and died at a village in Switzerland, July 16, 1806. De Lolme's principal work is *The Constitution of England; or an Account of the English Government; in which it is compared both with the Republican Form of Government and the other Monarchies in Europe*. It was first published in French at Amsterdam in 1771; the English translation, by another hand apparently, did not appear till 1775. The work, which flattered England, threw no new light on the subject, long enjoyed a high reputation, and reached a tenth edition (with Life, 1853), but has long been superseded; its author was called by Isaac D'Israeli 'the English Montesquieu.' In 1772 he also published anonymously in English, *A Parallel between the English Government and the former Government of Sweden*; ten years later, his *History of the Flagellants*; in 1796 an *Essay containing Strictures on the Union of Scotland with England*, and numerous political pamphlets. In 1816 Dr Busby tried to prove that De Lolme was Junius.

Delorme, MARION, a famous Frenchwoman, whose name figures too prominently in the history of the 17th century. She was born about 1612, at a village near Châlons-sur-Marne, and came at an early period of her life to Paris, where her great beauty and brilliant wit soon gathered a group of wealthy and high-born lovers round her. Even the great Cardinal Richelieu was not insensible to her charms, and revenged himself for her contempt by causing her to be separated from the ill-fated young Cinq-Mars, her love for whom was the one ennobling passion of her life. Among her lovers were, in succession, the Duke of Buckingham, Saint-Evremond, the Duc de Brissac, the Chevalier de Grammont, and Emeri, the Superintendent of Finance. During the first disturbances of the *Frondeurs*, her house was the rallying-point of the chiefs of that party, and in consequence Mazarin was about to fling her into prison, when she suddenly died in 1650. A curious tradition sprang up in France during the next century, to the effect that Marion had *not* died, but escaped to London; that she had married an English lord, had then returned to Paris, and married first a robber-chief, next a procurator of finance, and, finally, that she died in 1706; or, according to another account, even so late as 1741. Her story was treated by Victor Hugo in a drama; by Alfred de Vigny in his romance *Cinq Mars*. See Eugène de Mircourt's imaginative *Confessions de Marion Delorme* (3 vols. 1851).

Delos (called also in ancient times *Asteria*, *Ortygia*), an island in the Grecian Archipelago, the smallest of the Cyclades, is situated between the islands Rhenea and Mykonos. According to the mythological account it was at first a floating island, but was fixed to the bottom by Zeus in order that it might become a safe abode to Leto for the birth of Apollo and Artemis. Its earliest historical inhabitants were Ionians, and it appears to have been the centre of a great periodical festival held in honour of Apollo, both on the mainland and in the islands. In 426 B.C. Delos was purified by the Athenians, all the tombs were removed from it, and it was declared pollution for any birth or death to take place on it. Four years after they expelled the Delians from the island. After 146 B.C., when Corinth fell, Delos became the seat of extensive commerce. Its sacred associations, its great festival, its excellent harbour, and its situation in the direct route from southern Europe to the coasts of Asia, all combined to render it a port highly favoured by merchants. So great was the traffic of Delos that it is said 10,000 slaves changed hands here in a single day.

After flourishing for a considerable time, it was devastated in the Mithridatic war (87 B.C.), and from this calamity it never recovered. Little more than 1 sq. m. in area, it was noted for its palm-trees, and also for its brass, and the brazen vessels which it manufactured. The town of Delos, which stood at the foot of Mount Cynthus, a granite crag 347 feet high, is now a mass of ruins. Still, however, the remains of the great temple of Apollo, and of the colossal statue raised in his honour, may be distinctly traced. Since 1877 extensive investigations have been prosecuted in its ruins by Homolle for the French Archaeological Institute.

Delphi (now *Kastri*), an ancient Greek town in Phocis, celebrated chiefly for its famous oracle of Apollo, was situated about 8 miles N. of an indentation in the northern shore of the Gulf of Lepanto, at the southern base of Parnassus. Its original name, and that by which Homer invariably speaks of it, was Pytho. It stood in the centre of a district renowned for its classical associations. Occupying the vale of the Pleistus, it was seated in a semicircle like the area of a grand natural theatre, backed towards the north by two lateral spurs of Parnassus. These lateral ranges extend east and west around Delphi, and give rise also, from the point at which they approximate, to the famous fountain of Castalia, the holy water of the Delphian temple. The earliest inhabitants of Delphi are said to have come from Lycorea, a town upon one of the slopes of Parnassus, the inhabitants of which are supposed to have been Dorians. From the Delphian nobles were at first taken the chief magistrates and the priests of the temple, while the Pythia or priestess who delivered the oracle, at first always a young maiden, but latterly always a woman not younger than fifty, was usually selected from some family of poor country-people. In the centre of the temple was a small opening in the ground, whence arose an intoxicating vapour, believed to come from the well of Cassotis; and the Pythia having breathed this, sat down upon the tripod or three-legged stool, which was placed over the chasm in the ground, and thence delivered the oracle, which, if not pronounced at first in hexameters, was handed over to a poet, employed for the purpose, who converted it into that form of verse. As the celebrity of the Delphic oracle increased, Delphi became a town of great wealth and importance, famous not only in Hellas, but also among the neighbouring nations. Here the Pythian games were held, and it was one of the two places of meeting of the Amphictyonic Council (q.v.). The fourth temple, though the first built of stone, was destroyed by fire in 548 B.C., and during the succeeding century a fifth and last one was built by the Amphictyons at the cost of 300 talents, or £115,000. It was hexastyle, fronted with Parian marble, and adorned with statuary by Praxias and Androthenes. In 480 B.C. Xerxes sent a portion of his army to plunder the temple; but as they climbed the rugged path that led to the shrine, a peal of thunder broke overhead, and two huge crags tumbling from the heights crushed many of the Persians to death, while their comrades, struck with terror, turned and fled. It was plundered by the Phocians during the Sacred War, and was attacked by the Gauls in 279 B.C., who were said to have been repulsed like the Persians by portents. The splendour of Delphi subsequently excited the rapacity of many conquerors, and suffered severely by their attacks. Nero carried off from it 500 bronze statues; Constantine also removed many of its works of art to his own capital. In the time of Pliny, the number of statues in Delphi was not less than 3000, and within the temple for a long time stood a golden

statue of Apollo. The modern town of Kastri now occupies the site of Delphi, in the neighbourhood of the source of the still flowing Castalian spring. See A. Mommsen's *Delphika* (Leip. 1878), vol. iii. (1880) of Bouché-Leclercq's *Histoire de la Divination dans l'Antiquité*, and the *Cornhill Magazine* (1882).

Delphinapterus. See BELUGA.

Delphin Classics. an edition of the Greek and Roman classics (64 quarto volumes, 1674-1730) prepared by thirty-nine of the best scholars of the time, under the editorship, originally, of Bossuet and Huet, tutors to the dauphin, son of Louis XIV. The title-pages bear the words, 'In usum Serenissimi Delphini,' hence the name. Editions in octavo of particular authors, as Virgil and Horace, were often reprinted in England. The Delphin Classics are now esteemed of little value.

Delphinidae. See DOLPHIN.

Delphinium. See LARKSPUR.

Delta is the alluvial deposit formed at the mouth of a river from the deposition of the particles which it has held in suspension or rolled forward upon its bed. The term was originally applied to the tract of land thus formed (mainly within historical times) by the Nile, which, being inclosed by two main branches and the sea, has the form of the Greek letter Δ, delta. The formation of deltas depends more upon the absence of opposing currents at the mouth of the river than upon the quantity of sediment held in suspension when it reaches the sea. Deltas are consequently of almost invariable occurrence in inland lakes, in the quiet estuaries of the nearly tideless Mediterranean, and in the sheltered bays and gulfs of other seas. When, on the other hand, there are strong ebb-tides, or powerful oceanic currents, the detritus is carried off into the sea.

Delta Metal is an alloy consisting of copper and zinc—in other words, brass—to which some manganese has been added in the form of ferro-manganese, or spiegel-eisen which contains manganese. A little silicon is also used, but enough of this is usually present in ferro-manganese. The iron added by the use of these substances should be kept small in quantity. Delta metal has similar properties to phosphor-bronze, if, indeed, some of it is not simply manganese-bronze. The silicon and the manganese modify the properties of copper in the same way as phosphorus does in the case of phosphor-bronze (see BRONZE). Delta metal is used for parts of machinery and for ornamental work. See the patents of G. A. Dick, the inventor of delta metal, No. 5914, December 1883, and No. 6172, April 1884.

Deluc, JEAN ANDRÉ, geologist and meteorologist, was born at Geneva in 1727. Settling in England in 1773, he was appointed reader to Queen Charlotte, a post which he retained till his death at Windsor, 7th November 1817. He was author of thirteen works.

Deluge (through the French, from Lat. *diluvium*, 'a flood'). There is scarcely any considerable race of men among whom there does not exist, in some form, the tradition of a great deluge, which destroyed all the human race except their own progenitors. The classical story of Deucalion and Pyrrha is but a typical example of similar myths found everywhere, and savages and fathers of the church alike have argued that the shells, corals, and other marine objects often found on the tops of mountains, offered distinct proof of the historical reality of a deluge. That the Noachian deluge recorded in Scripture covered the whole earth and destroyed all mankind save one family, was the universal opinion until towards the close of the 18th

century, and is maintained even in Dean Buckland's *Reliquiæ Diluvianæ* (1823). The organic remains, on which the science of palæontology is now founded, were regarded as its wrecks, and were held to prove that it had covered every known country, and risen over the highest hills. In the progress of geology, it soon became evident that most of the stratified rocks demanded an earlier origin than a few thousand years, and the influence of the deluge was consequently restricted to the slightly altered superficial deposits; but many of these were, after a few years, found to belong to a period vastly anterior to any historical epoch, and to have been produced by long-continued and persistent agencies, differing totally from a temporary cataclysm. The more common modern opinion regards the flood of Noah as partial and local, although the universality seems fairly enough to be implied in the biblical description, and although the old theory has been revived by Mr H. Howorth in his work, *The Mammoth and the Flood* (1887). The late M. Lenormant, the most brilliant as well as erudite of orthodox scholars, in his great posthumous *Histoire Ancienne de l'Orient*, argues the partial character of the flood from the absence of all record of a deluge among the black races of the world, as the negroes and Papuans; and another Catholic scholar, M. l'Abbé Motais, in his interesting and learned work, *Le Déluge Biblique* (1885), maintains that this opinion is quite consistent with the exegesis of Scripture, with tradition, and the doctrine of the church, while it is the only theory that avoids all the ethnological and linguistic difficulties presented by the existence of the great negro and yellow races marked off so distinctly from the Noachian type. The deluge traditions of many primitive races are connected with religious mysteries, and it is scarcely true, as has often been asserted, that it is the Old Testament alone that gives a moral reason for the deluge sent upon the world. The Chaldean account discovered by George Smith presents a striking resemblance to the Genesis story, and agrees with it also in making the flood distinctly a divine retribution for human sin, although it of course differs from the Jewish account in being polytheistic instead of monotheistic. The vessel in which Xisuthros, the Chaldean Noah, sails, is a ship guided by a steersman, and others beside his own family are admitted into it. The flood is seven days at its height, and Xisuthros sends out in succession a raven, a dove, and a swallow. The ship finally rests on Rowandiz, the highest mountain of Eastern Kurdistan, and the peak which supports the heavens, instead of upon Ararat, the northern or Armenian continuation of the range. Babylonian tradition also confounds Noah with Enoch, for Xisuthros is taken to the skies immediately after coming out of the ark. Two deluge poems were amalgamated together in an Akkadian epic, in twelve books, describing the adventures of Gizdulbar, a great solar hero, to whom Xisuthros himself narrates the story. A translation of the best version—that of Haupt—is given by Professor Sayce in his *Fresh Light from the Ancient Monuments* (pp. 29-34).

De Lunatico Inquirendo. See INSANITY.

Delvino, a town of Albania, 45 miles WNW. of Janina, with a strong castle, and a trade in olive-oil and fruits. Pop. 6000.

Demades, an Athenian orator, of great extempore eloquence, but of no character or principle. A bitter enemy to the great Demosthenes, he promoted eagerly the Macedonian interest, and was sent away in safety by Philip when taken prisoner at Chæronea (338), but had not the grace to be honest even in his anti-patriotism, and was put to death for his treachery by Antipater in 318.

Demand and Supply. In Political Economy demand has reference to the quantity of goods asked for in the market, and supply has reference to the quantity of goods offered. The laws of demand and supply may be thus stated: when the demand exceeds the supply, competition grows stronger among the buyers, and prices rise, and when the demand falls short of the supply, competition grows stronger among the sellers, and prices fall; or thus, falling prices tend to lessen the supply and increase the demand, while rising prices tend to increase the supply and lessen the demand. A rise in prices tends to encourage production, while a fall in prices tends to discourage it. Conversely, consumption is promoted by falling and lessened by rising prices. The result is that demand and supply continually tend to equilibrium. Under such a system it is assumed that buyers and sellers or producers and consumers are free to fix their own prices. In other words, the laws of supply and demand prevail under a system of free competition.

Demavend, MOUNT, an extinct volcano of Persia, forming the loftiest peak of the Elburz Chain, which separates the low shores of the Caspian Sea from the high tableland of Persia. The height hitherto has been usually marked as 14,700 feet, but has been fixed by the Russian Caspian Survey at 18,600 feet.

Dembea, LAKE. See TZANA.

Dembinski, HENRY, a Polish general, was born near Cracow, 16th January 1791, entered the Polish army in 1809, and fought under Napoleon against Russia and at Leipzig. In the Polish revolution of 1830 he so distinguished himself that for a short time he was commander-in-chief of the national army; in 1833 he entered the service of Mehemet Ali. On the outbreak of the Hungarian insurrection, Kossuth appointed him commander-in-chief of the Hungarian army. He drew up a plan of the campaign, but was hampered by the jealousy of Görgei; and after the defeat of Kapolna (February 26-28, 1849) he was forced to resign his command. At Kossuth's resignation Dembinski fled to Turkey, but in 1850 he returned to France, and died at Paris, 13th June 1864. He was author of *Mémoires* (1833) and four other works.

Deme (Gr. *dēmos*), a subdivision of ancient Attica and of modern Greece. The *dēmoi* were townships or hundreds, subdivisions of the *phulai*, and were equivalent to the Dorian *kōmrai*, Lat. *pagi*; in the time of Herodotus they were 100 in number (10 in each *phulē*), afterwards 170; their origin was commonly referred to Theseus. The word *dēmos* early came to be applied to the commons, and survives significantly in our *democracy* and *demagogue*.

Demembré, or DISMEMBERED, a heraldic term to signify that the members of an animal are cut from its body.

Dementia. See INSANITY.

Dismembered.

Demerara, one of the three counties of British Guiana (q.v.), between the Abari and the Esse-quiho, takes its name from the Demerara River, which rises in the Maccari Mountains, in about 4° 40' N. lat., and after a northerly course of about 200 miles, enters the Atlantic at Georgetown. The mouth is 1½ mile wide, but is obstructed by a bar at low tides; the stream is navigable for 80 miles, and has many flourishing settlements on its banks.

Demesne was that portion of the lands of a Manor (q.v.) which the lord of the manor reserved for his immediate use and occupation.

Demeter, the Ceres of the Romans, was one of the chief divinities of the Greeks. She was the earth-goddess, the patroness of agriculture and of fruits, and her name itself most probably meant Mother-Earth (*gē mētēr*). She was the daughter of Cronus and Rhea, and was by Zeus the mother of Persephone (Proserpine), who was carried off while gathering flowers in the Nysian plain, in Asia, by Aidoneus (Pluto), the god of the nether world. Demeter wandered for some time in search of her daughter, and when she learned whither she had been carried, quitted Olympus in anger, and dwelt on earth among men, as at Eleusis, bringing blessings in her train. At length Zeus sent Hermes to bring back Persephone, and both mother and daughter then returned to Olympus, whereupon the earth again brought forth her fruits. As Persephone had eaten a part of a pomegranate in the under world, she was obliged to spend one-third of the year in the gloomy kingdom of her husband, returning to her mother the remainder of the year. Many later additions were made to this beautiful story, in which it is not difficult to see an allegorisation of the burial and revival of the seed-corn within the ground. The Latin poets made Enna, in Sicily, the scene of Proserpine's rape. The Eleusinia were held every year at Athens, in honour of Demeter and her daughter, as well as the Theomophoria, both there and in other parts of Greece. The Athenians revered her especially as the originator of civilised life and its arts, which all rest on the basis of agriculture. In art Demeter is represented fully clothed, a garland of corn-ears round her head, in her hand a sceptre, corn-ears, or a poppy, and sometimes with a torch and mystic basket. The worship of Demeter, known as Ceres, reached Rome from Sicily, and ultimately acquired great political importance. Her chief festival there was the Cerealia. See CERES.

Demetrius, or DMITRI. See RUSSIA.

Demetrius Phalereus, so named from the Attic demos of Phalerus, a seaport of Athens, where he was born about 345 B.C., was distinguished as an orator and politician. Though descended from a family of neither rank nor property, by his abilities and energy he rose to the highest honours at Athens. He was educated along with Menander in the school of Theophrastus, entered upon public life about 325, and soon made himself famous by his oratory. In 317 he was intrusted by Cassander with the government of Athens, and discharged its duties for ten years with such general satisfaction that the grateful Athenians heaped all kinds of honours upon him, and erected no fewer than 360 statues to his honour. During the later period of his administration he seems to have given himself up to dissipation; and when Demetrius Poliorcetes, king of Macedonia, approached Athens with a besieging army in 307, Demetrius, having lost the sympathies and co-operation of the Athenians, was obliged to flee. All his statues were demolished except one. He retired first to Thebes, but afterwards found refuge in the court of Ptolemy Lagi, at Alexandria, where he lived for many years, devoting himself to literary pursuits. On the death of his protector, Demetrius was expelled from the court of Egypt, retreated to Busiris in Upper Egypt, and died there from the bite of an asp in 283. Demetrius was the last of the Attic orators worthy of the name. His style was graceful, insinuating, and elegant; bearing, however, in its luxuriousness and tendency to effeminacy, the marks of a declining oratory. The list of his works (fifty in number) given by Diogenes Laërtius shows him to have been a man of most extensive acquirements.

Demi-bastion, in Fortification, differs from a Bastion (q.v.) in having only one flank instead of two and no curtain.

Demi-bastion.

Demidoff, a Russian family distinguished for wealth and beneficence, is descended from Nikita Demidoff, originally a blacksmith at Tula, who in the time of Peter the Great became famous as a manufacturer of arms, and amassed an immense fortune.

Of the numerous princes of the line, perhaps the most famous is Prince Anatol (1813-70), born at Moscow, but educated in France. He was always remarkable for his enthusiasm in letters and in the sciences; his principal work being his *Travels in South-east Europe* (4 vols. Paris, 1839-49). It contains very valuable scientific observations, and is magnificently illustrated.

Demi-lion, **DEMI-ROSE**, **DEMI-FLEUR DE LIS**, &c., in Heraldry, means, when an animal is spoken of, the upper half; and with an inanimate object, the dexter half parted per pale.

Demi-lune, in Fortification, is the name formerly given to the work now called a Ravelin (q.v.). See FORTIFICATION.

Demi-monde (Fr. *demi*, 'half,' and *monde*, 'world,' or 'society'), a term that came into vogue from the title of a play by the younger Dumas (1855), as applied to a class of women in large towns, and especially Paris, whose disregard for the proprieties prevents their being more than half recognised by society. The word covers women of all degrees of disrespectability, provided only they respect the elegancies of life.—*Demi-rep* is a similar 18th-century word, compounded clumsily enough, for a woman of more than doubtful reputation.

Demir-Hissar ('iron-castle'), a town of European Turkey, on a tributary of the Struma, 45 miles NE. of Saloniki. Pop. 8000.

Demise. See LEASE.

Demisemiquaver, half a semiquaver, or the 32d part of a semibreve. See MUSIC.

Dem'urge (from Gr. *dēmos*, 'people,' and *ergon*, 'a work'; hence a 'handicraftsman') was the name given in the cosmogony of the Gnostics to the creator or former of the world of sense. He was conceived as the archon or chief of the lowest order of the spirits or æons of the pleroma; mingling with chaos, he formed in it a corporeal animated world. He created man, but could impart to him only his own weak principle, the *psychē* or sensuous soul; therefore the highest, the really good God, added the divine rational soul, or *pneuma*. But the power of evil in the material body, and the hostile influence of the merely sensuous demiurge, prevented the development of that higher element. The demiurge holding himself to be the highest God, could not bring his creatures to the knowledge of the true Godhead; as the Jehovah of the Jews, he gave them the imperfect law of Moses, which promised merely a sensuous happiness, and even that not attainable; and against the spirits of the *hylē*, or world of matter, he sent only a psychical, and therefore powerless Messiah, the man Jesus. See Gnostics.

Demmin, an ancient town of Prussia, on the Peene, which is navigable for small vessels to this point, 29 miles S. of Stralsund by rail. It has manufactures of machinery, bells, ironwares, sugar, lime, and bricks, and a trade in grain, wool, coal, and iron. Pop. (1885) 10,546.

Democracy ('rule of the people,' from Gr. *dēmos*, 'the people,' and *krateo*, 'I rule') is a form of government in which power rests with the body of

the citizens. It is opposed to monarchy, the rule of one; to aristocracy, the rule of the 'best' or nobles; and to oligarchy, the rule of the few. It is government of the people by the people, and for the people, as opposed to government by a single chief or a dominant class.

Democracy was a great force in the ancient world, but as then prevalent it had certain characteristics, which very clearly distinguish it from its modern forms. In antiquity the democracy was associated with the city. There was no system of representation by which the people spread over extensive territories could send deputies to speak and act for them in a common parliament. In the ancient democracies, the people were, in the original sense of the word, citizens, who personally appeared and spoke and voted in the assemblies. Another great feature in the ancient world was the existence of a great number of slaves who had no political and few civil rights—i.e. a very large and important part of the population were not reckoned among the citizens at all. Hence it will be seen that the 'people' in the ancient democracy was limited in number, consisting of a city population, and excluding the labouring class or slaves. Thus constituted, the ancient democracy had a most interesting history. It attained to its highest and finest development in the Athens of Pericles before the outbreak of the Peloponnesian war. Besides being a conflict for the headship of Greece between Athens and Sparta, that war was a struggle for supremacy in the Hellenic world between the democratic and aristocratic principles, of which these cities were respectively the representatives and champions. It resulted in the overthrow of the Athenian democracy, but the struggle of the people against the rich and privileged classes continued in the Greek cities as long as they retained their independence. At Rome, too, the history of the city is to a large degree the record of popular struggle against the privileged and wealthy classes. Quiescent for about two hundred years after the reforms of the 4th century B.C., it broke out afresh at the time of the Gracchi, and ended with the triumph of a great chief of the democracy, Julius Cæsar. But this triumph meant the end of the republic, and the permanent rule of a single head, as consolidated under Augustus.

Among the Germanic tribes which overthrew the Roman empire, as among most peoples at a similar stage of development, the general body of freemen had considerable power. But the term democracy properly refers to communities in a comparatively advanced state of political evolution, and it would be an anachronism to apply the theories and problems connected with the word to nations still in the tribal stage.

With the growth of the republics of medieval Italy, and of the cities of Flanders and Germany, began a democratic movement similar in some respects to that of ancient times. It was similar, inasmuch as it was associated with city life, but it differed from the ancient democracy, in so far as slavery ceased to be an important factor, and the development of the medieval cities was controlled or affected by the great feudal states which had now risen. As the great modern states have become consolidated, the cities which played so important a part in medieval life have been absorbed in them. The process has been a slow one, for Venice was an independent republic till the close of the 18th century. Hamburg was fully incorporated in the German empire only in 1888. In the city life which thus came to a close, the struggle between rich and poor, between privileged classes and the people, was more or less present.

The modern democracy differs essentially from the ancient and medieval forms. The people no

longer consist merely of a body of burgesses limited in number, but of millions of men inhabiting extensive countries. A government on such a basis is rendered possible through the representative system, by which the vast electorate choose a convenient number of deputies, on whom the legislative and other functions are conferred. Another important point of difference is the abolition of slavery, serfdom, and the other unfree conditions which formerly prevailed. Freedom of conscience, freedom in the choice of one's residence and profession, have been more or less fully realised. We must also note the progress towards the abolition of all privileged classes, and towards equality before the law.

The modern democracy, as we now see it, is the result of a gradual process of development continued through centuries amidst the severest struggles. Such struggle will appear to be inevitable, when we consider that democracies have grown up in large states in which absolutism formerly prevailed, and in which the military system prevails even yet. Among the decisive steps in the modern struggle of the people against the old classes and systems should be noted the long contest of the Dutch against Spain, the great English revolutions of 1642 and 1688, the war of American Independence in 1776, the great French Revolution of 1789, and the revolutionary periods of 1830 and 1848. The English revolutions of 1642 and 1688 established parliamentary rule in England, though on a narrow basis. Yet they had the important result of proving the *fitness* of a new type of government, which further became a model for similar institutions in other countries. The greatest event in the evolution of democracy, however, was the French Revolution of 1789; though it failed for the time, it shook the old system to its foundations; it everywhere spread new ideas, and raised questions that could not again be set aside. The revolution of 1830 showed that the reactionary conditions prevalent after Waterloo had no claim to permanency. The revolutionary movements of 1848, which affected France, Italy, Austria, and Germany, were apparently a failure, yet they overthrew what remained of the feudal system in western and central Europe. But the most significant thing connected with that period is the fact that only a few years afterwards universal suffrage was introduced in all the countries where its influence had been felt. Governments which had been most active in suppressing the revolution found it expedient to adopt its cardinal principles.

To England has been given the great historic mission of working out the methods on which the democracy has so far been realised. Her parliament, first constituted under Simon de Montfort and Edward I. in the 13th century, was, as we have seen, firmly established by the long contest with the Stuarts. After so many centuries of experience, trial, and struggle, the English parliament has become the mother of parliaments. England has not been the first, however, to bring democratic institutions to their full development. The Reform Bill of 1832 conferred the franchise on the middle classes; but it was not till the reforms of 1867 and 1885 that she has approximated to universal suffrage. The British government is now substantially a democracy, modified so far by older forms, the monarchy and the House of Lords. In many countries which have adopted parliamentary institutions, the power of the people is much more seriously curtailed; in Germany, for example, by a sovereign claiming to be of divine right. The German emperor may be regarded as wielding a power co-ordinate with that of the people, and resting on the army. The position of his chancellor does not depend on a parliamentary majority—he is the servant of the

emperor; yet while not depending on a parliamentary majority, he finds it expedient and even necessary to have one. The government of the United States, as also of the several states that constitute the Union, is democratic.

As we have seen, the distinctive features of the modern democracy are the widest *personal freedom*, by which each man has the liberty and responsibility of shaping his own career; *equality* before the law; and political power in the form of universal suffrage, exercised through the representative system. With these are associated universal education, and on the continent of Europe universal liability to military service. In Britain and the United States universal liability to military service exists also in theory as regards the militia. On the European continent it is a momentous fact imposed upon its peoples by the necessities of the struggle for existence, which the moral development of mankind has not yet been able so to regulate as to put an end to war. Anglo-Saxon countries are happily freer from such necessities. It is an interesting fact, however, that Prussia, which was the first great nation to adopt universal education, was also the first to introduce universal military service.

It is important to remember that the growth of the modern democracy has gone hand in hand with the general development of the most advanced nations of the world. The consolidation of the political power of the people is the result of far-reaching causes operating on a great scale throughout the history of modern nations. The growth of the democracy is intimately connected with the growth of every other factor in the social life. For example, the different stages in the rise of the democracy could be paralleled by the improvements in the art of printing. The development of the democracy has on the one hand created the demand for cheap literature and cheap newspapers, but it has also on the other hand depended on the supply of them. Further, the growth of the cheap newspaper and of cheap literature depends on the industrial development, on the improvement of our technical capacities and resources, on man's growing mastery over nature. To the production of the daily newspaper a thousand technical appliances are subsidiary. Steam and electricity are the great forces that move the vast mechanism on which society is now based. In fact the growth of the democracy is intimately connected with an industrial and technical development which has culminated in the railway, the penny post, the electric telegraph, and the steam printing-press. The peculiar influence of the human voice has not been superseded, yet it is chiefly through the telegraph and the printing-press that the modern democracy obtains the education which the ancient democracy received in their popular assemblies and in the daily intercourse of the market-place.

Thus it will be seen that the democracy as we now have it is an outcome of the general historic movement of modern times, and that it is a fact which is not yet accomplished, but is still in process of making. What its ultimate results for good or evil may be, no man can predict. Scarcely any one, however, will deny that it has greatly raised the average level of intelligence and morality in modern nations. The life of the citizen from the day he enters the elementary school is a continual process of education, and it brings with it in abundant measure the discipline of responsibility. It carries with it also the safeguard of publicity. The public interests are protected by incessant watchfulness and public criticism. On the other hand, the drawbacks of democratic government are obvious enough. Such vast masses of electors are too much controlled by governments, caucuses, and

special interests; real interests are concealed under party watchwords, and sacrificed to them. Popular passions are liable to upset the plans of experienced policy, and the demagogue too often ousts the true statesman from his well-merited position in the esteem of the people. It may be added that in the administration of foreign affairs, the changefulness and publicity usually characteristic of the democracy place it at a disadvantage as compared with the secrecy, continuity, and tenacity of a government like that of Russia.

Much has been written on the merits and demerits, the advantages and disadvantages of the democracy. It really perhaps concerns us more to observe the fact that it is the inevitable outcome of the prevalent historic forces, that it has a great function in modern history, and that it is the duty of the citizen and statesman to do their duty under it, and to adapt it to the material, intellectual, and moral improvement of men.

See the articles GOVERNMENT, REPRESENTATION; De Toqueville, *Democracy in America* (1862); Motley, *Historic Progress of American Democracy* (1869); Freeman, *Comparative Politics* (1873); Sir T. E. May, *Democracy in Europe* (1878); Sir H. S. Maine, *Popular Government* (1885); Bryce, *The American Commonwealth* (1888).

Democrats, a political party in the United States. So early as Washington's first administration, a party known variously as Republicans or Democrats had already been formed, who desired to limit the federal power, and to increase that of the states and of the people; about 1808 the title of Republicans as synonymous with Democrats disappeared. See REPUBLICANS. Electing Jefferson president in 1801, the Democrats remained in power till 1841, and the administration was in their hands also in 1845-49, in 1853-61, and in 1885-89. Democratic presidents have been Jefferson, Madison, Monroe, John Quincy Adams, Jackson, Van Buren, Polk, Pierce, Buchanan, Cleveland. For the positions taken by Democrats on the most prominent issues, see the article UNITED STATES. During President Cleveland's term of office the party committed itself to the principle of a reform of the tariff.

Democritus, an illustrious Greek philosopher, was born at Abdera, in Thrace, about 470 or 460 B.C. Of his life little is known. The statement that he was first inspired with a desire for philosophic knowledge by certain Magi and Chaldeans whom Xerxes had left at Abdera, on his Grecian expedition, is as untrustworthy as that which represents him as continually laughing at the follies of mankind. His extensive travels, however, through a great portion of the East, prove the reality of this desire, as does also his ceaseless industry in collecting the works of other philosophers. Democritus was by far the most learned thinker of his age. He had also a high reputation for moral worth. He appears to have left a strong impression of his disinterestedness, modesty, and simplicity on the mind of the community, for even Timon the scoffer, who spared no one else, praised him. The period of his death is uncertain. He lived, however, to a great age. Only a few fragments of his numerous physical, mathematical, ethical, and musical works are extant. These have been collected by Mullach (Berlin, 1843). Cicero praises his style, and Pyrrhon imitated it.

Democritus's system of philosophy is known as the *atomic system*, which is considered to have been founded by Leucippus. Its essence consists in the attempt to explain the different phenomena of nature—not like the earlier Ionic philosophers, by maintaining that the original characteristics of matter were *qualitative*, but that they were *quantitative*. He assumes, therefore, as the ultimate elementary ground of nature, an infinite

multitude of indivisible corporeal particles, *atoms* (see ATOM), and attributes to these a primary motion derived from no higher principle. This motion brings the atoms into contact with each other, and from the multitudinous combinations that they form, springs that vast and varying aggregate called *nature*, which is presented to our eyes. Democritus did not acknowledge the presence of *design* in nature, but he admitted that of *law*. 'The word *chance*,' he says, 'is only an expression of human ignorance.' He believed strictly in secondary or physical causes, but not in a primary immaterial cause. Life, consciousness, thought, were, according to him, derived from the finest atoms; those images of the sensuous phenomena surrounding us, which we call mental representations, were, according to him, only material impressions, caused by the more delicate atoms streaming through the pores of our organs. Democritus boldly applied his theory to the gods themselves, whom he affirmed to be aggregates of atoms, only mightier and more powerful than men. His ethical system, spite of the grossness of his metaphysics, is both pure and noble. Such fragments of his writings as we possess contain beautiful, vigorous, and true thoughts concerning veracity, justice, law, order, and the duties of rulers; while, in a spirit not alien to the teaching of Christianity, he looks upon an inward peace of heart and conscience as the highest good, the end and the aim of all virtuous endeavour.

Demodex. See ACARUS.

Demogeot, JACQUES CLAUDE, a French *littérateur*, born 5th July 1808 at Paris, lectured at Beauvais, Rennes, Bordeaux, and Lyons, and was appointed in 1843 to the chair of Rhetoric at the Lycée St-Louis at Paris. Most of his books treat of the history of literature; the chief are *Les Lettres et les Hommes de Lettres au XIX. Siècle* (1856); *Histoire de la Littérature française* (1857), an admirable hand-book; *Tableau de la Littérature française au XVII. Siècle* (1859); and *Histoire des Littératures étrangères* (2 vols. 1880). His poems are little known.

Demoiselle (*Anthropoides*), a genus of birds in the crane family (Gruidæ), differing from the true cranes in having the head and neck quite feathered, and the beak no longer than the head. The Demoiselle (*A. virgo*) is about 3 feet in length

Demoiselle (*Anthropoides virgo*).

from the point of the bill to the tip of the tail, and the top of its head is about $3\frac{1}{2}$ feet from the ground. It is remarkable, like its relatives, for elegance and symmetry of form, and grace of deportment. The feathers covering the upper part of the wing are much elongated, as in the cranes. The general

colour of its plumage is gray, but the sides of the head are adorned with two elegant white tufts, and the breast bears long blackish feathers. The demoiselle is an African and Asiatic bird, but visits Greece and other parts of the south of Europe. To the same genus belongs the beautiful Stanley Crane (*A. paruliseus*), a larger and taller bird found in the East Indies.

Demoivre, ABRAHAM, a distinguished mathematician, was born at Vitry, in Champagne, 26th May 1667. A Protestant, he fled to England in 1685, on the revocation of the Edict of Nantes, and there long supported himself by private tuition and public lecturing. The appearance of Newton's *Principia* incited him to increased devotion to mathematical studies, and at last he ranked among the leading mathematicians of his time. He was a member of the Royal Society of London, and of the Academies of Berlin and Paris. The *Philosophical Transactions* of London are enriched by many contributions from his pen; and he was so esteemed by the Royal Society that they judged him a fit person to assist in the decision of the famous contest between Newton and Leibnitz for the merit of the invention of fluxions. He died in London, 27th November 1754. Among his published works are *Annuities upon Lives* (1725), *Miscellanea Analytica de Seriebus et Quadraturis* (1730); and *The Doctrine of Chances* (1718 and 1738), dedicated to Sir Isaac Newton. Demoivre's name is well known from its association with a useful trigonometrical formula—viz. that, where k is any real quantity, $\cos k\theta + i \sin k\theta$ is always one value of $(\cos \theta + i \sin \theta)^k$.

Demonetisation. See BIMETALLISM.

Demonology, the doctrine that relates to demons, a body of spiritual beings inferior in rank to deities proper, but yet capable of influencing human affairs. The earlier and more widely-spread conception of the demon was merely that of a more or less powerful and intermediate agent between gods and men, at one time resolving himself into a kind of special guardian or patron-spirit, at another acting as the minister of the divine displeasure. The gradual differentiation between the beneficent and the malignant qualities of demons resulted in the division into good spirits or guardian-angels and evil spirits or devils; and Christian theology, developing earlier Jewish ideas—themselves powerfully modified by the influence of Persian dualism—worked up the one class into an elaborate hierarchy of angels and arch-angels, the other into a formidable host of fallen angels or devils, considered as continually employed in frustrating the good purposes of God, and marshalled under one master-spirit, the devil proper or Satan, the supreme impersonation of the spirit of evil. The guardian-angel corresponds closely to such conceptions as the Roman *genius* and even the famous *daimon* of Socrates. To primitive man the demon was but one of the thousand spiritual beings who controlled every one of the causes of nature, and whose favour must be purchased by constant tributes of respect and worship. It was perfectly consistent with primitive philosophy that the manes or ghosts of the dead should continue after death the influence they enjoyed in life, and thus should pass into the higher class of deities. The essential distinctions between the divine and the human that seem so fundamental to modern minds did not occur to those whose notions of the visible and invisible universe alike were entirely animistic; and thus we find that the savage makes no clear distinction between ghosts and demons, and that his conception of the demon is constructed on the model of the human soul, of course with any number of terrible and superhuman qualities

superinduced. It is not merely family affection, but actual fear and considerations of prudence, that lead to the worship of ancestors and of the dead; and the good or bad fortune of living men is attributed to the direct interference of the invisible spirits with which the whole air around is swarming. These spirits may not only affect the fortune of the individual, but may even enter into his body, and cause internal diseases and such other inexplicable phenomena as frenzy, wild ravings, hysterical epilepsy, and the like. The very etymology of such words as *cataplexy* and *ecstasy* points plainly to a time when there was no metaphor in their meaning. Such is the explanation of disease offered at the present day by savage man all over the world, and such was also the belief of the semi-civilised ancient Egyptians and Babylonians. Indeed, it disappeared but slowly before the progress of scientific medicine, and continued to reappear in survivals strangely perplexing on any other explanation. Hence the function of the exorcist arises naturally as a means of effecting a cure by expelling the demon, and we find him daily exercising his skill in Africa, and even in China and India. A careful distinction is made by sorcerers as to whether the infesting demon *possesses* or *obsesses* his victim—i.e. controls him from the inside or the outside. In early Christian times those demoniacally possessed, or *energumens*, were grouped into a class under the care of a special order of clerical exorcists, and after the time of St Augustine the rite of exorcism came to be applied to all infants before baptism. Indeed, exorcists still form one of the 'minor orders' of the Catholic Church.

Reverting to the animistic theory of demonology, we find how well it harmonises with widely-spread notions in folklore of phantom-dreams—nightmare (A.S. *mara*, 'a crusher'); the Slavonic vampires, or witch-ghosts, who suck the blood of living victims; *incubi* and *succubi*, like Adam's wife Lilith in the rabbinical story (Assyrian *lilit*, 'a succubus'), demons who consort with women and men in their sleep and by whose means children may be engendered between demons and women; the Hindu *rakshas*, malignant and gigantic demoniacal ogres who can at will assume any shape; and witches, who have confessed a thousand times to being possessed with a familiar spirit, and who own allegiance in particular to the master-demon, Satan. Other embodiments of the spirit of evil are the Celtic and Teutonic Giants, and the Ogres of southern romance, who destroy men and devour their flesh; the Norse Trolls, one-eyed, malignant but stupid monsters; the Drakos and Lamias of modern Greece; the Lithuanian Laume; the Russian fiery and flying snakes, Koshchei the Deathless, Baba Yaga, a hideous old hag who flies through the air in a fiery mortar, propelled with a pestle, and the Morskoi Tsar, or king of the waters, with his daughters, the ubiquitous swan-maidens of romance. No mythology is richer than the Slavonic in malignant male and female demons and fiends (*chorti*, 'devils'), gloomy shadows of old nature myths and degraded forms of the great deities of an earlier religion, a combination of the most heterogeneous elements flung together in the most perplexing confusion. Traces remain of an original dualism between a great black and a white god (*Byelun*); but besides this and those fiendish forms already mentioned, Mr Ralston enumerates the *karliki*, or fiendish dwarfs; *lyeshnie*, silvan demons resembling the fauns and satyrs of Greek mythology; *vodyannie*, or water-sprites; *vodzushnie*, demons who ride the whirlwinds; *domovnie*, or domestic spirits like the Scotch *brownies* and the Lithuanian *kaukas*; and the *rusalka*, a kind of Naiad or Undine.

Demons with specialised functions exist in mythology everywhere, as the Japanese Oni, who bring on winds, themselves living at the centre of the storm; the Chinese air-dragons, whose battles bring on waterspouts; the demons of floods in old Egyptian and Akkadian mythology; the spectres and phantoms that infest the sea; the nixies of northern Europe, and the kelpies of Scotland, who haunt pools to drown unwary travellers, and naturally hate bridges, although elsewhere many bridges as well as other superhuman works have been erected, usually in miraculously short periods of time, by demons, often at the command of powerful magicians like Michael Scott. Sometimes the devil even consents to build a church for the reward of the soul of the first that enters it. Others again are those sirens who, by their unearthly beauty or the charm of their singing, draw on unwary youths to their ruin; most famous of these, the romantic Lorelei of the Rhine. Again, particular animals, chiefly those with power to harm man, are favourite hosts for demons to inhabit, especially the serpent, but also the cat, the hedgehog, the hare, the fox, the he-goat, the raven, the wolf—the old Norse Fenris, and the dog, especially if black in colour, like the dog in *Faust*. The madness of dogs, with its peculiar horror, itself opens up a strange chapter in the history of demonology.

One of the most systematic of demonologies is that elaborated by the Moslem theologians. The Jinn (sing. Jinnee) were created two thousand years before Adam, but sinned against God and were degraded from their original high estate. The greatest among them was Iblees (Ellis), who was cast out by Allah for refusing to worship Adam as made of earth, he himself having been formed of smokeless fire. The Sheytáns form his host; other species of subordinate fiends are the Jánn, the least powerful, also 'Efreetis (Afrits) and Márids, the last the most powerful. Eminent among the evil Jinn are the five sons of Iblees—Teer, who brings about calamities, losses, and injuries; El-Aawar, who encourages debauchery; Sót, who suggests lies; Dásim, who causes hatred between man and wife; and Zelembóor, who presides over places of traffic. Inferior demons are the Ghoul, often in human form and devouring the bodies of the dead like the Russian werewolves; the Sealáh, found in forests; the Delhán, living in islands; and the Shikk, shaped like a human being halved lengthwise. The Jinn assume various shapes, sometimes as men of enormous size and portentous hideousness. They live chiefly on the mountains of Káf, which encompass the whole earth, and their evil influence may be averted by talismans and invocations, and pre-eminently wise magicians like Solomon may command their services. They consist of forty troops, each troop containing six hundred thousand. See chapter ii. of Lane's *Arabian Society in the Middle Ages* (edited by Stanley Lane-Poole, 1883).

The subject of dualism, or the division of all the invisible powers into two great armies of good and evil demons, ranged under the supreme impersonations of good and evil, will be discussed under ZOROASTER, and here it is sufficient to say that it modified the whole later Jewish and Talmudic demonology, and reappeared in the Manichean heresy. To it is due the distinction between the *demon* and the *devil*, a notion which seems fundamental to the modern moral sense, but was foreign to the earlier demonology, according to which all the specially malignant qualities and the love of evil for its own sake become characteristic of the latter. The Vritra and the other night-powers, the Panis, of the Vedic hymns, are as yet hardly more than personifications of merely physical evil, not inherently and absolutely wicked; while the

Loki of the ancient Scandinavians, their nearest approximation to a personification of evil, was rather a demigod than a devil, not essentially hostile to the other deities, although he works them mischief enough; and the four archdemons of the Rabbins, Samaél, Azazel, Asaél, and Mac-cathiel, seem to have been originally nothing more than personifications of the elements as energies of the deity. Even the name Lucifer ('the light-bearer'), the fallen angel of the morning star, fits ill with a conception of a devil utterly and hopelessly evil. The widely-spread belief that demons are lame accords well with a supposed fall from heaven and an original state of innocence. It is not a little striking at any rate to find the same characteristic in Hephaistos, Wayland the Smith, and the Persian Ashma—the Asmodeus of the Book of Tobit, the 'Diable Boiteux' of Le Sage. The sootiness of his abode and his blackness of colour are persistent characteristics, although, indeed, some West African negroes have a white devil. The usual cloven feet of the devil in European folk-tales, often the last mark of identification, when even the horns and the tail are hidden, is a reminiscence of the Greek satyr and the forest-sprites of old Teutonic and other folklore. The ugliness of the medieval representations of the devil in religious art, as may be seen in the fantastic gargoyles of many churches, was but a part of the early church's policy of degradation to which the native deities were subjected, and from which sprung the medieval belief that the various gods of the old heathen world were the devils or degraded angels of Scripture. This notion is familiar to readers of *Paradise Lost*, although Milton makes an ingenious poetic use of it that is all his own. And even the medieval devil, with all his terror, had strange limitations to his power, especially perhaps in the folklore of the north. He is often ludicrously outwitted, and his machinations foiled by some obvious enough device or verbal quibble. It is not merely the weakest saint upon his knees that can baffle his infernal schemes, but some country-fellow who beats him at his own weapons, and whom afterwards he will have in hell at no price. The old Scotch notion of Satan as grown so much the more dangerous from the accumulated wickedness and wisdom of six thousand years is hopelessly inconsistent with the archfiend of Norse folklore.

The early Christian idea of hell, the abode of the demons, owed many of its features to the Jewish Gehenna, with its perpetual fire, the horror of its sacrifices, and its loathsome worm; and the characteristics of Moloch and other primitive fire-gods became associated with the devil, degraded from a fire-god to a mere powerful spirit. The Jinn of Arabian mythology, who are slaves of the lamp and ascend as clouds of smoke, serve also to show how fundamental was the notion of a fire-fiend which passed, though under degraded form, into Christian theology. Consistent with this is the widespread belief in Europe that the devil cannot touch or cross running water, of which poetic use is admirably made in the magnificent phantasy of *Tam o' Shanter*. Again, the struggle between Balder and the deadly powers of winter in the Norse mythology was spiritualised and amplified into Christ conquering Death and Hell and releasing the spirits from prison; and the old northern ideas of wintry cold personified into a powerful and malignant demon, under new influences passed to swell the attributes of the Christian devil, whose dreary abode provided those torments of frost as well as fire familiar to readers of Dante. Herein is the origin of the folklore notion that the home of the demons was the north, and hence the inveterate

English preference for burial on the south side of a church. No stories are more common than those of compacts with the devil, sometimes written in blood, by which a man gave away his soul for wisdom, wealth, power, or other gratifications to be enjoyed for a certain number of years. The classical story in this kind is that of Faust, which the genius of Goethe has made an imperishable part of the intellectual birthright of Europe.

Raising the devil or his inferior demons was a feat within the power of the medieval sorcerers and masters of the black art, and elaborate formulas for the purpose are gravely given in the books of magic. This unholy art was made punishable by death by James I., and his law remained upon the statute-book of England till the reign of George II. The worship of the devil was a usual feature of the witches' sabbath, and the name is often applied still to the strange dances and other religious rites by which many tribes in India and elsewhere avert the anger of malignant deities. It must be understood that there is no conscious homage to the principle of evil as opposed to good, as the objects of worship are merely deities powerful for harm as well as for help, considered almost as entirely outside any moral considerations, like the demons of unmixed primitive religion everywhere.

See the articles ANGEL, ANIMISM, DEVIL, EVIL, EXORCISM, HELL, SERPENT-WORSHIP, WEREWOLF, WITCHCRAFT, ZOROASTER; also Horst, *Demonomachie* (2 vols. 1817), and *Zauberbibliothek* (6 vols. 1821-26); Ukert, *Ueber Dämonen, Heroen, und Genien* (1850); Bastian, *Der Mensch in der Geschichte* (3 vols. 1860); Tylor's *Primitive Culture* (2 vols. 1871); Roskoff's admirably learned *Geschichte des Teufels* (2 vols. 1869); and for its facts, Moncreu D. Conway's *Demonology and Devil-lore* (2 vols. 1879); also some of the older books, as Bodin, *De Magorum Demonomania* (1581), and the like.

De Morgan, AUGUSTUS, son of Colonel De Morgan of the Indian army, was born in 1806, in Madura, Madras Presidency. Educated at several private schools, he 'read algebra like a novel' (novels themselves he devoured insatiably); but after four years at Trinity College, Cambridge, he graduated as only fourth wrangler (1827). As a result of his revolt from his early evangelical training, he did not take orders. He was appointed first professor of Mathematics in University College, London, after its foundation in 1828. In 1831 he resigned this office, but was reappointed in 1836, and continued in that capacity till 1866. An energetic worker, he was secretary of the Astronomical Society (1831-38 and 1848-54), and held other offices therein. His writings are very numerous. Besides being a mathematician of the first order, he was extensively and minutely versed in the history of the mathematical and physical sciences. He also devoted himself to the development of the Aristotelian or 'Formal' Logic, to which he has given so symbolical a shape as to make it seem like a branch of Algebra, and wrote on the calculation of Insurances and on the Decimal Coinage. His works include *Elements of Arithmetic* (1831); *Algebra* (1835); *Numbers and Magnitude* (1836); *Trigonometry and Trigonometrical Analysis* (1837); *Essay on Probabilities* (1838); *Formal Logic* (1847); *Arithmetical Books* (1847); *Book of Almanacs* (1850); *Budget of Paradoxes* (1872), reprinted from the *Athenæum*. De Morgan also wrote treatises on the Differential and Integral Calculus; and contributed largely to the *Penny Cyclopædia* (850 articles) and many scientific journals. He died 18th March 1871. His library of about 3000 volumes was purchased by Lord Overstone, and given to London University. See *Memoir of Augustus de Morgan*, by his wife (1882).

Demosthenes, an able Athenian general, who in 425 B.C. assisted Cleon to reduce Sphacteria,

and who in 413, being sent to Sicily to the relief of Nicias, fell, fighting bravely, into the hands of the Syracusans, and was put to death.

Demosthenes, the greatest orator of Athens and of Greece, was born about 383 B.C. He lost his father at an early age. The considerable inheritance bequeathed to him was reduced by the neglect or the fraud of his guardians, and when he came of age he proceeded to prosecute them. The litigation was long and complicated, and though he gained verdicts in his favour, most of his inheritance was irretrievably lost. The importance of this litigation was that it compelled Demosthenes to the study of the law, gave the first exercise to that doggedness and strength of will which was to mark him through life, and by reducing him to poverty, drove him to the pursuit of law as a means of living. At Athens the parties to a suit were compelled to plead their cause themselves, but they could not be prevented from getting their speeches composed for them by a professional 'speech-writer' or 'logographer.' Demosthenes became a logographer, and soon acquired a lucrative practice. Up to the age of thirty Demosthenes confined himself to 'speech-writing,' and gained considerable reputation as a constitutional lawyer. His most famous constitutional law speech is one which he delivered personally in support of Ctesippus against Leptines (354 B.C.). He seems to have lacked by nature all the physical qualifications of a great orator, and to have acquired them solely by indefatigable self-discipline and training. At about the age of thirty he made his first appearance as a politician; he continued to practise as a logographer until he was about forty, by which time he had made a fortune sufficient to enable him to devote himself exclusively to political life until he died, at the age of about sixty-one.

At the beginning of his political career danger threatened Greece from the north, from Macedonia, a country which though at that time considered by the Greeks as semi-barbarous, and of no account in Greek politics, was destined within the lifetime of Demosthenes to destroy the liberties and the political existence of Greece. Demosthenes' claim to fame as a statesman rests on the fact that he foresaw the danger threatened by Philip of Macedon from the beginning, and that he from the outset advocated a policy which might have saved Athens and Greece. The three cardinal features of his policy were that the rich should submit to direct taxation for the purposes of the war; that the poor should submit, for the same purposes, to a diminution of the public expenditure on national festivals; and that rich and poor alike should render personal military service instead of employing mercenaries. Intelligent as was the Athenian democracy, it was not intelligent enough to see that Demosthenes' forecast was right, and his opponents' wrong; and, consequently, it was only when events justified Demosthenes, that is to say, when it was too late, that his policy was adopted. Philip's attack on the state of Olynthus gave occasion to the *Olynthiæcs*, which, with the orations against Philip, the *Philippics*, are the greatest speeches made by Demosthenes. Athens made war with Philip on behalf of Olynthus, but having failed to save the city, found peace expedient. During the next few years (346-340) Demosthenes was engaged in forming an anti-Macedonian party, and in indicting Æschines for betraying Athens in the negotiations for the peace just concluded with Philip. War again broke out in 340, ending in the fatal battle of Chæronea (338). But Athens, having learned to trust Demosthenes, did not withdraw her confidence. The philo-Macedonian party, however, were encouraged to seize on a proposal to present Demosthenes with a public

crown as an occasion for his political destruction. The trial was at length held in 330, when in the famous speech *On the Crown* Demosthenes gloriously vindicated himself against *Æschines*. In 324 *Harpalus*, the treasurer of Alexander the Great (who had succeeded Philip), absconded to Athens with an enormous sum of money. This money was placed in the state treasury, under the care of Demosthenes and others, and when Alexander demanded it, half was missing. Demosthenes was accused, condemned, and escaped from prison into exile. The evidence does not seem to have warranted the verdict, which was probably given on political grounds, Demosthenes having offended both the Macedonian party and the extreme patriots. In 323 Alexander died, and Demosthenes was recalled from exile to head a fruitless attempt to throw off the Macedonian yoke. The battle of Crannon ended the revolt. Demosthenes fled to Calauria, and being there captured by Macedonian troops, poisoned himself, 322 B.C.

Demosthenes began life with a nervous, timid nature, and, unfortunately, as a boy was allowed by his mother to shirk the physical exercises and gymnastic training which formed part of the ordinary education of the young Athenian. He grew up with a tendency to effeminacy, which showed itself in an affection for luxurious clothing, and still more in his conduct as a citizen soldier; for although at Chersones he may have displayed no more cowardice than did the other Athenians who ran away, he was far from exhibiting the heroic bearing which distinguished Socrates at Delium. His timidity made him unsocial, and his water-drinking habits cut him off still more effectually from society. His luxury may have reached the point of extravagance: he was certainly lavishly generous in the discharge of all claims on him, public and private. Whether his effeminacy amounted to immorality, as was charged against him, is a question which cannot be answered off-hand in the negative. The natural defects which were to be seen in his private life may be traced in his public career; but here it is their conquest by force of will and determined adherence to a lofty purpose which has rightly given him his great name. His nervousness and timidity disqualified him for political life and public speaking; these defects he combated till he conquered them. His natural incapacity for amiability rendered him unsympathetic to the pleasure-loving Athenians; he compelled their respect by his intellectual power and the purity of his patriotism. The want of sympathy, however, he never overcame, and so he never obtained the hold over the Athenians which it would have been good for them that he should possess. In all democracies every politician who has led the masses at his own good-will has known on occasion how, if not to flatter, at least to say the thing that is pleasant; but Demosthenes' nature did not permit him to say pleasant things. Even this serious practical deficiency could not prevent his contemporaries from eventually recognising his force of character and steadiness of noble purpose. Still less has it weighed with posterity.

In the oratory of Demosthenes it is not difficult to trace the character of the man reflected. His resolute hard work and his infinite capacity for taking pains are seen in the high finish which distinguished his speeches above those of every orator. His moroseness is mirrored in the abuse of which he was too great a master; his want of amiability in the absence of humour. His nervousness betrays itself in his over-anxiety to argue, in his lack of ease and flow. But as in his life so in his speeches, all faults are blotted out by his unaffected earnestness, his entire devotion to his country, his intel-

lectual loftiness, and his high political morality. These great qualities are the source of the dignity, the pathos, the might, majesty, and dominion of his political orations. Even these qualities, however, would not have raised him to the highest pinnacle in the fane of eloquence had he not possessed the ear and the mind of the artist in words, the former of which gave to his speeches the marvellous melody they possess, the latter the variety of vocabulary, which is one of Demosthenes' characteristics. Nor must it be forgotten that the way for Demosthenes had been paved by great predecessors. The summit on which he stands rests on the labours of Lysias, Isocrates, and others. Finally, oratory, to be great, must have great themes, and it is not in every age that they are forthcoming. Demosthenes had the lot, tragic but triumphant, of saving, though all else was lost, the honour of his country.

For the life of Demosthenes, A. Schäfer's *Demosthenes und seine Zeit* (2d ed. 1882) eclipses all other works, good as are the hand-books of Brodribb (1877) and Butcher (1881). The most exhaustive literary criticism is contained in Blass's *Attische Beredsamkeit* (1877). The best text is that of Bekker (1854). Kennedy's English translation (5 vols. 1852-63) is a monument of scholarship.

Demotica, a town of European Turkey, on a tributary of the Maritza, 31 miles S. of Adrianople by rail. It is the seat of a Greek bishop, and has manufactures of silks and pottery. Pop. 8000. Charles XII. of Sweden resided here from February 1713 to October 1714.

Demotic Alphabet. See **HIEROGLYPHICS**.

Dempster, THOMAS, a professor famous for his learning, and a miscellaneous and voluminous writer, was the son of Thomas, laird of Muireask, Aberdeenshire, and was born about 1579. He was educated at Turiff, Aberdeen, Cambridge, Paris, Louvain, Rome, and Douay. A zealous Catholic, he was elected to several provincial professorships, and at Paris he was for seven years professor in the Collège des Grassins, de Lisieux, and de Plessy. But a brawl resulted, it is said, in Dempster's having to retreat to England. He soon returned to the Continent, bringing with him a beautiful wife, and at Pisa in 1616 obtained a professorship; but his wife's infidelities marring his peace, he removed to Bologna, where he became professor of Humanities, and where his wife completed her shame by eloping. Pursuing the fugitives, he was stricken with sickness, and died at Bologna, 6th September 1625. Dempster's not too veracious autobiography forms part of his *Historia Ecclesiastica Gentis Scotorum* (Bologna, 1627)—an erudite work in which, however, his desire to magnify the merits of his country often induced him to forge the names of persons and books that never existed, and to unscrupulously claim as Scotchmen writers whose birthplace was doubtful. It was edited by David Irving for the Bannatyne Club in 1829, and the manuscript is still preserved in the Bibliothèque Nationale, Paris. There is a selection from his Latin poetry in Johnstone's *Delitæ Poetarum Scotorum*.

Demulcents (Lat. *demulceo*, 'I soften'), bland and lubricating liquid substances, taken by the mouth, for the purpose of soothing irritation of the mucous membranes, and promoting the dilution of the blood, and the increase of the secretions. Demulcents are chiefly composed of Starch (q.v.), or Gum (q.v.), or of substances containing these, dissolved in water; sometimes also of oily matters, or the white of eggs, and other albuminous or gelatinous substances largely diluted. The decoction of althea, or marsh-mallow, is a favourite form of demulcent.

Demurrage is an allowance made to a ship-owner by the freighter, for the detention of the ship in port beyond the specified time of sailing. The demurrage is properly the delay itself, but the term is generally used to signify the compensation due for the delay. A certain number of days, called lay-days or lie-days, are allowed for receiving and discharging cargo, and it is usually stipulated in charter-parties that the freighter may detain the vessel, either for a specified time, or as long as he pleases, after the expiration of these days, on paying so much *per diem* for overtime. Whether the days for which demurrage is due are *working days* (i.e. with Sundays and holidays excepted) or *running days* will, in the absence of special agreement, depend upon the custom of the port. All the ordinary causes of detention, such as port-regulations, the crowded state of the harbour, and the like, are at the risk of the freighter, and demurrage must be paid, though it be proved that the delay was inevitable. But demurrage is not due where the delay arose from detention of the ship by a public enemy, or from hostile occupation of the port; and it cannot, of course, be claimed where the fault lay with the owners themselves, or the master or crew of the vessel. The demurrage ceases as soon as the vessel is cleared for sailing, though she should be prevented from actually doing so by adverse winds. When the days of demurrage are limited by special contract, and the ship is detained beyond them, the sum due as demurrage under the contract will be taken as the measure of the loss for the further time which may be claimed in the form of damages. It will be open, however, to both parties to show that the rate thus fixed *per diem* is either too high or too low. When the time allowed for loading and discharging expires, including the extra days if such be stipulated, the master will be entitled either to sail or to claim damage for detention.

The allowance of 1½d. per oz. claimed by the Bank of England for giving gold coin in exchange for bullion is also called demurrage.

Demurrer, in English law, is a form of pleading whereby a party, admitting, for the sake of argument, his opponent's allegations, says they are not sufficient in law to support his opponent's case. A demurrer must be argued in court before the pleadings can proceed further. Demurrer to evidence and demurrer to a criminal indictment are now obsolete. If a prisoner wishes to object to the sufficiency in law of an indictment, his best course is to plead to the indictment, and, if convicted, to move in arrest of judgment.

Demy, a particular size of paper. In that of printing paper, each sheet measures 22 inches by 17½; drawing-paper, 22 by 17; and writing-paper, 20 by 15½.

Demy (i.e. *half-fellow*), the name borne by the scholars of Magdalen College, Oxford.

Denain, a town in the French department of Nord, near the Scheldt and Selle rivers, 20 miles NNE. of Cambrai by rail. It lies in the centre of an extensive coalfield, and has important iron-works, and with manufactures of beetroot sugar and brandy. An obelisk marks the scene of Marshal Villars' victory over the allies under Prince Eugene, 27th July 1712. Pop. (1872) 10,442; (1886) 16,115.

Denarius (*deni*, 'ten each'), the principal silver coin among the Romans, was equal to ten *asses*, but upon the reduction of the weight of the *as*, the denarius equalled sixteen of it. It was first coined 269 B.C. Its weight at the end of the Roman commonwealth is estimated at 60 grains, while under the empire the weight was 52½ grains of silver. The value of the denarius under the republic

was thus rather more than 8½d., and of the later

Denarius of the earliest kind, actual size; weight, 60·6 grains.

period about 7½d. From *denarius* come the Persian *dinar* and the English slang *deaner*, 'a shilling.'

Denary Scale. See NOTATION.

Denbigh, a parliamentary and municipal borough, the county town of Denbighshire, 30 miles W. of Chester by rail. It stands near the middle of the vale of the Clwyd, on the sides and at the base of a rugged steep limestone-hill. The castle, whose imposing ruins crown this hill, was built in 1284 by Henry Lacy, Earl of Lincoln, on the site of a fortress erected by William the Conqueror. The newer part of Denbigh was built at the bottom of the hill, after the destruction and desertion of a great part of the town on the top of the hill, about 1550. Denbigh has manufactures of shoes and leather; but it is more a place of genteel retirement than of commerce. Pop. (1851) 5498; (1881) 6491. With Ruthin, Holt, and Wrexham, Denbigh sends one member to parliament. In 1645 Charles I. took refuge in the castle after the battle of Rowton Heath. The garrison surrendered to the parliamentary forces after a siege of two months. It was shortly afterwards dismantled. The fortifications have an area of a square mile in extent. A lunatic asylum for the five counties of North Wales was erected near the town in 1848. A noble institution for the maintenance and education of twenty-five orphan girls, and twenty-five day pupils, was built here in 1860, with funds in the hands of the Drapers' Company of London, from money left to them in 1540 by one Thomas Howell, a Welshman.

Denbighshire, a county of North Wales, on the Irish Sea, and between the Dee and the Conway. With 8 miles of coast, it is 41 miles long, 17 broad on an average, and 603 sq. m. in area, being the sixth in size of the Welsh counties. The surface is partly rugged and mountainous, with some beautiful and fertile vales, as the vale of the Clwyd, 20 miles by 7. In the north is a horseshoe range of hills, 65 miles long, and convex to the coast. The highest hill is Cader Fromwen, 2563 feet; and many others rise above 1500 feet. The rocks are chiefly Silurian clay and graywacke slates, with some granite and trap, and bands of Devonian, Carboniferous, and Permian strata. There occur coal, iron, slates, flags, millstones, limestone, lead, and copper. The chief rivers are the Dee, Conway, Elwy, and Clwyd. The Rhaiadr waterfall is 200 feet high in two parts. Llangollen vale is famed for romantic beauty and verdure, amid hills of savage grandeur. The climate is mild in the lower parts, but cold and bleak among the hills, where small hardy sheep and ponies are reared. About two-thirds of Denbighshire are under cultivation; its corn, cheese, butter, and live-stock are greatly esteemed. It is also well timbered. Salmon are caught in the rivers. The chief towns are Denbigh, Wrexham, Ruthin, Holt, Llangollen, Llanrwst, Abergele, and Ruabon. Pop. (1801) 60,299; (1841) 88,478; (1881) 108,931. Denbighshire returns three members to parliament. It was anciently occupied by the Ordovices, a powerful tribe, not entirely subdued by the Romans till the

time of Agricola. Of British or pre-Roman remains there still exist tumuli, two kistvaens or stone cells, barrows, and forts. To the times of the Welsh and Saxon struggles are referable the Pillar of Eliseg, near Llangollen, and the dikes of Offa and Watt. The dike of Offa, king of Mercia, to keep out the Welsh, was a ditch, with small forts on mounds at intervals, and ran from Herefordshire to the estuary of the Dee; Watt's dike ran on the east side of Offa's dike, and parallel to it. Wrexham Church is one of the 'seven wonders of Wales.' Chirk Castle is a fine Edwardian stronghold, lately restored.

Dendera (Gr. *Tentyra*; Coptic *Tentore*, probably from *Téi-n-Athor*, the abode of Athor), a village of Upper Egypt, once a populous town, and the capital of the sixth nome of the 'southern kingdom,' situated near the left bank of the Nile, in 26° 13' N. lat., 32° 40' E. long., is celebrated on account of its temple, one of the finest and best preserved structures of the kind in Egypt, dating from the period of Cleopatra and the earlier Roman emperors. The temple measures 220 feet in length by about 50 in breadth, and has a noble portico or hypostyle hall supported on twenty-four columns. The walls, columns, &c. are covered with figures and hieroglyphics, among which are still to be seen the contemporary portraits in profile of Cleopatra and her son; but the beauty of the Egyptian queen is not apparent in her portrait, which belongs to almost the most degraded period of conventional art in Egypt. On the ceiling of the portico is a zodiac, in which the crab is represented by a scarab. Beyond the portico are a hall of six columns and several rooms, which once contained altars, the sacred boats, perfumes, vestments for the religious ceremonies, and offerings of first-fruits, and the like (Mariette, *The Monuments of Upper Egypt*). There are several other sacred buildings at Dendera, including a temple of Isis. The temples stand within a wall of unbaked bricks, 1000 feet long on one side, and in some parts 35 feet high. The people of Tentyra were peculiar for their detestation of the crocodile, which led to a violent religious war with the city of Ombos, where the reptile was worshipped.

Dendermonde (Fr. *Termonde*), a town of Belgium, in the province of East Flanders, situated at the confluence of the Dender and the Scheldt, 18 miles E. of Ghent by rail. The principal buildings are the town-house and the church of Notre Dame, containing two pictures by Van Dyck. The manufactures are linens, cottons, and beer. Louis XIV. besieged it in vain in 1667, but Marlborough succeeded in taking it in 1706. Its fortifications, destroyed in 1784, were restored in 1822. Pop. 8883.

Dendrerpeton, a small lizard-like carboniferous amphibian, found by Lyell and Dawson in the interior of the hollow trunk of an upright *sigillaria* in Nova Scotia. It belongs to the wholly extinct order of Stegocephala or Labyrinthodonts (q.v.)

Dendrites, the name given to thin films of mineral matter which assume branching shapes that resemble moss or seaweed. These films occur as coatings on the faces of fissures and joints in rocks or on the surfaces of bedding-planes, and have often been mistaken for fossils. The hydrous oxide of manganese is the mineral that generally assumes this form.

Dendrolites (Gr. *dendron*, 'tree'; *lithos*, 'stone'), a general term sometimes applied to fossil stems, branches, or other fragments of trees.

Dendrology is that department of botany which deals with the natural history of trees and shrubs. See ARBORICULTURE, TREES.

Dendrophis (Gr., 'tree-snake'), a genus of non-venomous snakes in the sub-order Colubriiformes. They are tropical, and especially oriental, in their distribution; diurnal, active, and arboreal in habit; and feed chiefly on tree-lizards. The head is long and distinct from the neck, the gape is wide, the body and tail are very slender, the colours are vivid and like their surroundings.

D'Enguien. See ENGHIEU.

Dengue, or BREAK-BONE FEVER, also called DANDY and BUCKET FEVER, is a disease first certainly known to have occurred in 1779-80 in Egypt, parts of the East Indies, and probably in Philadelphia. Since that time there have been great epidemics in India and Further India (1824-25), America and West Indies (1826-28), Southern United States (1850), East Africa, Arabia, India, and China (1870-73), besides numerous minor outbreaks. The disease occurs almost exclusively in the tropics, in hot weather, and in towns either near the sea-coast or on large rivers. It is characterised by sudden onset, with high fever, and extremely violent pains in the bones, muscles, and joints; by a remission, usually at the end of one or two days, during which the patient feels almost well; and after one or two days more by a second period of fever, less severe than the first, which lasts for two or three days. Each attack of fever is often accompanied by a well-marked skin-eruption. Though often followed by much emaciation and loss of strength, it is very rarely fatal or succeeded by serious after-effects. It occurs almost always in well-marked epidemics; but observers are much divided upon the question whether it is communicable directly from the sick to the healthy. See Hirsch, *Geographical and Historical Pathology*, vol. i.

Denham, SIR JOHN, a Caroline poet, was the only son of an Irish judge, himself of English birth, and was born at Dublin in 1615. He was educated in London and at Trinity College, Oxford, where Wood tells us he was 'a slow dreaming young man, and more addicted to gaming than study'—a taste from which his own essay against gaming (1651) did not cure him. In 1634 he married and went to live with his father at Egham in Surrey, an estate to which he succeeded four years later. At the outbreak of the Civil War he was high-sheriff of Surrey, and he immediately joined the king. He fell into Waller's hands on the capture of Farnham Castle, and was sent prisoner to London, but soon permitted to repair to Oxford. In 1641 he produced *Sophy*, a feeble tragedy which was acted with great applause at Blackfriars. Next year was issued his long poem, *Cooper's Hill*, a poetical description of the scenery around Egham, itself still read, but more famous in the merits of its greater successors, Pope's *Windsor Forest*, avowedly an imitation, and Garth's *Claremont*. The final form of the poem is that published in 1655, all the changes in which, according to Pope, were made 'with admirable judgment.' Here first appeared its finest lines—the famous apostrophe to the Thames:

O could I flow like thee, and make thy stream
My great example, as it is my theme!
Though deep yet clear, though gentle yet not dull,
Strong without rage, without o'erflowing full.

In 1647 Denham was engaged in the performance of secret services for Charles I., but these being discovered, was obliged to flee to Holland and France. In 1650 he collected money for the young king from the Scots resident in Poland, and he made several journeys into England on secret service. At the Restoration he was appointed surveyor-general of works, and created Knight of the Bath. He was a better poet than architect,

but he had Christopher Wren to his deputy. In 1665 he married a young girl, who soon showed such open favour to the Duke of York that the poor poet became crazy for a few months. Soon after his recovery his wife died suddenly, not without suspicion of poison—a charge which Pepys evidently believed. Denham's last years were miserable betwixt poverty and the satires of Marvell, Butler, and others. He died early in 1669, and was buried in Westminster Abbey. His *Elegy on Cowley*, written in the short interval between recovery from frenzy and his death, is one of his most successful poems, and is much less obscure and laboured, ungrammatical, and overlaid with tedious moralising, than usual. His other works, as the *Destruction of Troy*, a paraphrase of part of the *Aeneid*, and especially his satirical doggerel verses, are comparatively worthless. 'Nothing,' says Dr Johnson, 'is less exhilarating than the ludicrousness of Denham; he does not fail for want of efforts; he is familiar, he is gross; but he is never merry.' His fame rests securely on *Cooper's Hill*, but more securely still on the commendations of Dryden, Pope, Swift, and Johnson. He is especially eulogised for his *strength*, as Waller is for his *sweetness*; indeed, Dryden's critical judgment stands expressed in the words that *Cooper's Hill* 'for the majesty of its style is and ever will be the standard of exact writing.'

Denia, a port on the coast of the Spanish province of Alicante, near Cape St Martin. It exports grapes, raisins, and fruit, and has a population of 8623.

Denina, CARLO GIOVANNI MARIA, an Italian author, was born 28th February 1731, at Revello, in Piedmont, studied at Turin, and in 1756 became professor of Rhetoric in the university of Turin. In 1777 he published anonymously at Florence his *Discorso sull' Impiego delle Persone*, in which he sought to show how monks might be transformed into useful members of society. This cost him his chair, and caused his banishment. In 1782 he went to Berlin on the invitation of Frederick the Great. Here he lived for many years, and wrote many historical works. In 1804 he dedicated to Napoleon his *Clef des Langues* (1804), and was in consequence appointed imperial librarian at Paris, where he died 5th December 1813.—Denina's principal works are *Delle Rivoluzioni d'Italia* (3 vols. 1770) and *Storia dell' Italia Occidentale* (6 vols. 1810), besides works on ancient Greece, Frederick the Great, and Prussia.

Denis, St, the traditional apostle of France and first Bishop of Paris, who suffered martyrdom in the 3d century. He was sent from Rome about 250 to preach the gospel to the Gauls. After various detentions at Arles and other places, he arrived in Paris, where he made numerous proselytes. The Roman governor of this part of Gaul ordered Denis to be brought before him, along with other two Christians. As they continued firm in their faith, in spite of threats, they were cruelly tortured, and afterwards beheaded, in 272 or in 290. Gregory of Tours, Fortunatus, and the Latin martyrologists, state that the bodies of the three martyrs were thrown into the Seine, but were recovered and buried by a Christian woman. At a later period, a chapel was built over their tomb. In 636 King Dagobert founded on the spot an abbey, called St Denis, which soon grew to be one of the richest and most important in the whole kingdom, and was long the sepulchre of the French kings. The collection entitled the *Acts of St Denis*, written about the end of the 7th or beginning of the 8th century, has no historical value. The Greek Church identifies St Denis with Dionysius

the Areopagite, first Bishop of Athens. The Western Church celebrates his memory on the 9th of October. For a long period his name was the war-cry of the French soldiers, who charged or rallied to the words 'Montjoye Saint-Denys!'

Denison, JOHN EVELYN, for fourteen years Speaker of the House of Commons, and afterwards Viscount Ossington, was born 27th January 1800, at Ossington, Nottinghamshire. Educated at Eton and Christ Church, Oxford, he entered parliament in 1823, and was a Lord of the Admiralty 1827-28. In 1872 he retired from the Speaker's chair, and shortly after was created Viscount Ossington. He was a D.C.L. of Oxford; and it was on his suggestion that the *Speaker's Commentary* to the Bible was undertaken. He died 7th March 1873.—His brother, GEORGE ANTHONY DENISON, Archdeacon of Taunton, was born in 1805, and educated at Eton and Christ Church, Oxford, in 1828 being elected a Fellow of Oriel. In 1843 he became Vicar of East Brent, Somerset; in 1851 Archdeacon of Taunton. In 1854 proceedings were taken against him for heresy, contained in three sermons on the *Real Presence*, and he was condemned to be deprived of all ecclesiastical preferments; but on appeal to the Court of Arches and the Privy-council, this judgment was quashed. He has been a leader of the High Church party, a strenuous opponent of secular education, and an advocate of the restoration of the confessional. He was chairman of the Committee of Convocation which condemned *Essays and Reviews* and Bishop Colenso's works. See his delightful *Notes of my Life* (1878).—Other brothers were Edward, Bishop of Salisbury (1801-54), and Sir William Thomas, Governor of New South Wales and Madras (1804-71).

Denman, THOMAS, BARON, was born in London, 23d February 1779, graduated at Cambridge, and entered Lincoln's Inn in 1806. He was associated with Brougham in the courageous defence of Queen Caroline (1820), and shared his consequent popularity. He sat in parliament from 1818-26, and was Attorney-general in Earl Grey's administration in 1830-32; he succeeded Lord Tenterden as Lord Chief-justice of England in 1832, and was raised to the peerage in 1834. He retired from the bench in 1850, and died 22d September 1854. See *Memoir* by Sir Joseph Arnould (2 vols. 1873).—His fourth son, the RIGHT HON. SIR GEORGE DENMAN, was born 23d December 1819, studied at Cambridge, and entered Lincoln's Inn in 1846. He represented Tiverton in parliament in 1859-65 and 1866-72; in the last year he was raised to the bench of the Court of Common Pleas, receiving the customary honour of knighthood, and in 1873 he became a judge of the High Court of Judicature.

Denmark (Dan. *Danmark*), the smallest of the three Scandinavian kingdoms, consists of the peninsula of Jutland and a group of islands in the Baltic, and is situated between 54° 33' and 57° 45' N. lat., and 8° 4' and 12° 34' E. long., excepting the small island of Bornholm, which lies in 15° 10' E. long. Denmark is bounded on the N. by the Skagerrak; on the E. by the Cattegat, the Sound, and the Baltic; on the S. by the Baltic, Little Belt, and Sleswick; and on the W. by the North Sea. The area of Denmark Proper is a little less, the population a little more, than half that of Scotland. The population of Denmark Proper in 1870 was 1,784,741; in 1886 (including the Farøe Islands) it was estimated at 2,108,000. In 1887 the population of Copenhagen had reached 289,900. In 1880 there were five towns in Denmark, besides the capital, with over 10,000 inhabitants—viz. Aarhuus (24,831), Odense (20,804), Aalborg (14,152), Randers (13,457), and Horsens (12,652).

The following table gives the main divisions of the kingdom, along with its dependencies:

	Area in Eng. sq. miles.	Population in 1880.
Denmark Proper, comprising the islands of Zealand, Funen, Laland, Falster, &c., and the peninsula of Jutland....	14,731	1,969,030
The Farøe Islands.....	513	11,220
Iceland.....	40,300	72,445
Greenland (region free from ice).	33,885	(1885) 9,914
Danish W. I. Islands—St Croix, St Thomas, and St John....	138	33,703
	89,567	2,096,381

Except in Bornholm (q.v.), the surface of Denmark is very similar in every part of the kingdom, and is uniformly low, reaching its highest point in Eiers-Bavnehøj, in south-east Jutland, which is only 564 feet above sea-level. The country presents little variety, except in its low isolated hills, but does not leave an impression of monotony; in the islands and in the south-east of Jutland the landscape is broken by noble forests, green meadows, and fertile fields; and even in the west and north of the mainland the wide stretches of moorland are clothed with heather, and have a solemn beauty of their own. The coast seldom rises even to low cliffs; generally it is flat, skirted by sand-ridges and shallow lagoons, especially along the west side, where the dunes cover an area of nearly 225 sq. m. The east coast is much indented by bays, useful for navigation and valuable for their fisheries; and here and in the islands are many good harbours. Both the continental portion and the islands are penetrated deeply by numerous fjords, the largest being Limfjordi, which intersects Jutland, and has insulated the northern extremity of the peninsula since 1825, when it broke through the narrow isthmus which had separated it from the North Sea. There are about seventy light-houses along the shores of Denmark, and seven lightships (see SOUND). From its formation, the kingdom can have no rivers, properly so called; its streams, called *Aa*, are mostly large brooks. There are several important canals, however, including in Jutland works for the canalisation of the Guden-Aa, its largest stream, and of the Limfjord; and lakes abound in all parts of the kingdom, the most considerable being found in Zealand. The centre and west of Jutland is nearly bare of wood, but in the other parts of the peninsula the forests cover about 215,000 acres, and in the islands over 291,000 acres. The beech, which flourishes more luxuriantly in Denmark than in any other land, is almost universally predominant, although three centuries ago the oak, now comparatively rare, was the characteristic Danish tree. Peat, which is got in abundance from the bogs, brown coal or lignite, and seaweed generally take the place of wood as fuel. In minerals Denmark is poor. Porcelain clay and some coal are found in Bornholm, and fuller's earth, potter's clay, saltpetre, chalk, and a poor marble occur in several parts of the kingdom, while some amber is collected on the west coast of Jutland. The climate is modified by vicinity to the sea, and is considerably milder, and the air more humid, than in the more southern but continental Germany. Mists are frequent, as are also sea-fogs on the west coast; and rain, snow, or hail falls over the country on 150 days on an average in the year. The annual rainfall is 23 to 25 inches. Westerly winds prevail; in the spring a cold, dry wind, known as the *skaz*, blows from the north-west, and whirls clouds of fine sand from the coast inland, frequently doing irreparable damage to the crops. The mean temperature ranges from 44° to

47° F. The transitions from winter to summer are rapid, and scarcely broken by the intervention of spring or of autumn. The climate is, however, not unhealthy, except in the low-lying islands, such as Laland, where the short and sudden heat of the summer occasions fevers.

The soils of Jutland are generally light, but those in the south-east part and in the islands are stronger; about 80 per cent. of the area of Denmark is productive, and of the remainder about one-sixth is in peat-bogs. Nearly half the population is engaged in agriculture; the land for the most part is parcelled out into small holdings, and this is encouraged by the laws, which since 1849 have prohibited the throwing of small farms into large estates. In 1888, of 223,892 tenancies not 2000 were over 144 acres in extent; there were 150,000 cottars and labourers cultivating land of from three to twelve acres; and the 'peasant farms,' varying from 12 to 144 acres—the majority under 50—numbered close upon 72,000. A third of the whole kingdom is arable, while over two-fifths is in meadow, pasture, or fallow land. Nearly four-fifths of the arable land is under oats, barley, or rye, and little over a twenty-third part under wheat. Flax, hemp, potatoes, and leguminous plants are also raised; lucerne has been introduced, and the cultivation of the beet-root has increased of late years. Barley is largely exported, but the imports of breadstuffs greatly exceed the exports. The raising of cattle is taking more and more the place of arable farming in Denmark, and has now become one of the chief sources of wealth. Much progress has of late been made in this direction owing to the efforts of government and of various institutions; bull and stallion shows have been promoted by royal grants, breeding farms have been similarly encouraged, and the farmers have been instructed by lectures on the various forms of cattle disease and other subjects. Dairy produce has largely developed, and the export of butter more than doubled in the years 1882–87—an increase attributed to improved methods and the co-operative dairy system, which is now very successfully worked in over 200 establishments (see DAIRY FACTORIES); in 1888 there were 2200 centrifugal cream separators (see CREAM) in daily use. Within the same period of six years the export of bacon was quintupled, that of cheese trebled, and of horses nearly doubled, while the export of cattle and sheep slightly decreased. 19,880,000 eggs were exported in 1877, and 72,480,000 in 1885, the great development of this trade being the direct result of the efforts of a company for improving the breed of Danish fowls. In 1881 there were 1,470,078 cattle of all kinds, 347,561 horses, 1,548,613 sheep, and 527,417 swine.

In 1880, 23 per cent. of the inhabitants were returned as engaged in manufacturing industries, which, although not yet of great importance, show a marked advance within recent years. Machinery, porcelain and delf wares, and bricks are leading manufactures; beet-root sugar refineries are increasing, and the distilleries, though declining, are still numerous; there are ironworks, over eighty tobacco-factories, and several paper-mills in Copenhagen, Silkeborg, and elsewhere; and there are many large steam corn-mills. Generally, in spite of the scarcity of fuel in the country, steam-mills are taking the place of the windmills, and though the peasants still continue to manufacture much of what they require within their own homes, linens and woollens, as well as wooden shoes, are now increasingly made in factories. The fisheries (including the lobster and oyster fisheries) and the mercantile marine employ less than 3 per cent. of the people.

The principal articles of export are cattle, sheep, swine, butter, hams, hides, wool, grain, fish, eggs, meat, and woollen goods. Among the imports are textile fabrics, cereals, and flour, manufactures of metal and timber, coal, oil, salt, coffee, sugar, and tobacco. About two-thirds of the export trade is carried on in native vessels. The total value of the imports in 1880-85 ranged from £12,650,000 in 1880 to £16,028,602 in 1883; and of the exports in the same period from £9,014,520 in 1885 to £11,103,476 in 1883. The bulk of the foreign trade is with Germany, Great Britain, and Norway and Sweden. In 1887 the mercantile marine consisted of 3324 vessels, including 281 steam-ships; total tonnage, 272,500. In 1886 there were 1214 miles of railway open, of which about 1000 miles belonged to the state; in 1886 there were 2523 miles of state telegraph lines.

Elementary education is widely diffused, although in this regard Denmark is no longer so pre-eminent as formerly; it is compulsory for children between the ages of seven and fourteen years, poor parents paying only a nominal sum towards the government or parochial schools, of which there are about 3000. There are training colleges for teachers, and classical and other higher education is afforded by a large number of colleges in the more important towns, with the university of Copenhagen (1300 students) for the centre of the entire system. Denmark has also a theological seminary, a royal surgical college, a veterinary and agricultural school, and numerous military, technical, and commercial schools, while fifty 'people's high schools' provide instruction in agricultural subjects. There are three public libraries in Copenhagen, of which the Royal Library, with 500,000 volumes, is especially rich in oriental and Icelandic MSS. The established religion is Lutheran, to which the king must belong; but complete toleration is enjoyed in every part of the kingdom. The Reformation was introduced in 1536, when the church revenues were seized by the crown. Denmark is divided into seven dioceses, in which there were 1353 clergy in 1885. There were in 1880 only 17,526 persons not belonging to the Lutheran Church, of whom 3946 were Jews, 2985 Roman Catholics, 1363 Calvinists, 1722 Mormons, 3687 Baptists, and 1036 Irvingites.

The government of Denmark is a constitutional monarchy, the king being assisted by a cabinet of seven ministers. The crown was elective until 1660, when the people and clergy, impelled by hatred towards the nobles, invested the sovereign (Frederick III.) with absolute power, and declared the succession to the throne hereditary. From that time the crown exercised absolute rule till 1831, when a constitution was granted. This proving unsatisfactory, was superseded in 1849 by the form of government which, with some alterations, Denmark now enjoys. The national assembly or Rigsdag consists of the Folkething and Landsting, which meet annually, the members receiving a fixed allowance during their sittings. The Landsting is composed of sixty-six members, of whom twelve are nominated for life by the king, while the remainder are elected for a term of eight years by certain bodies representing the large taxpayers of the kingdom. The members of the Folkething, whose number is fixed by statute in the proportion of one to every 16,000 of the population, are elected for three years by practically universal suffrage. To this body all budgets must first be submitted; but in the years 1877-87, when the government had a minority in the lower house, the king was induced to give the royal ratification to successive 'provisionary budgets,' which had never received the assent of the Rigsdag. Nevertheless the financial condition of Denmark is sound

and prosperous. The total revenue for the financial year 1885-86 was £2,981,534, and the expenditure £2,779,763. The budget estimates for 1887-88 and 1888-89 show slight deficits. Since the war of 1866, the government has maintained a comparatively large reserve fund, to meet any sudden emergency. That fund stood in 1887 at £990,000. In 1888 the national debt was £10,723,203, or over £5 per head of the population; but as the investments of the state (in telegraphs, &c.) amount to nearly £5,000,000, this proportion is reduced to less than £3. The decimal system was introduced in 1875, the unit being the *kroner*, or crown, of 100 *öre*; the average rate of exchange is 18 *kroner* to the pound sterling. The Danish army in 1887 numbered 1495 officers and 58,067 men, inclusive of the landwehr; but only a sufficient establishment for garrison purposes is maintained, and the peace strength was 319 officers and 16,334 men. The total war strength is about 50,000 men, to which an extra reserve of 14,000 could be added on emergency. Conscription prevails, and the period of military service is divided into eight years in the line and reserve, and eight in the extra reserve. The navy is recruited by levies from the coast districts. The fleet was represented in 1887 by thirty-two steamers (of which nine were ironclads). The navy numbered in 1888, 134 officers and 1477 men. Besides Copenhagen (q.v.), the only fortresses are the coast defences at Helsingør (Elsinore), Fredericia, Korsør, Frederikshavn, and Hals. The arsenal is at Copenhagen.

History.—The early history of Denmark is lost in the twilight of the saga-period, out of which loom dimly the figures of its heroes, their brave deeds, and daring voyages. Within its borders the Celts had first their home, and from its shores the Angles and Saxons sailed in the 5th century to the conquest of England; while in their place the Danes from Zealand settled on the deserted lands, extending their sway as far south as the Eider. One of their earliest kings, Harald Hildetand, fell in battle against the Swedes in 695; and shortly afterwards a branch of the Ynglinger occupied Jutland, where they held a footing for two centuries. One of their kings, Harald Klak, received baptism in 826 from Ansgar (q.v.); but the introduction of Christianity did not at once place any check on the long-accustomed inroads on Frankish territory, or on the piratical expeditions of the Vikings, although the country was soon torn by dissensions between the adherents of the old and new faiths. Gorm the Old, who drove the Ynglinger from the peninsula, and first united the mainland and islands under one rule, was the bitter enemy of Christianity; and although his death in 936 gave fresh vigour to the diffusion of the new faith, yet even its ultimate success was only insured by the zealous support it received from Gorm's grandson, Canute (q.v.). On his death in 1035 the three kingdoms of his Anglo-Scandinavian empire separated, and his sister's son, Svend Estridsen (1047-76), ascended the throne of Denmark, founding a princely line that flourished 400 years. Internal dissensions and external wars weakened the country, and the introduction of a feudal system raised up a powerful nobility, and ground down the once free people to a condition of serfdom. Waldemar I. (1157-82) added Rügen to the other Wendish districts of Mecklenburg and Pomerania, and extended his sway over Norway also. Under Waldemar II. the conquests of Denmark extended so far into German and Wendish lands, that the Baltic was little more than an inland Danish sea. The jealousy of the German princes and the treachery of his vassals combined to rob him, however, of these brilliant conquests, and his death in 1241 was followed by a century of

anarchy and inglorious decadence of the authority of the crown, during which the kingdom was brought to the brink of annihilation. Under his great-grandson, Waldemar IV., Denmark made a transient recovery of the conquests of the older Waldemars, rousing the jealousy of the Hanseatic League (q.v.), and the national laws were codified. From his death in 1375 till 1412, his daughter, the great Margaret, widow of Hakon VI. of Norway, ruled not only that country and Denmark, but in course of time Sweden also, with so light yet firm a hand that for once in the course of their history the three rival Scandinavian kingdoms were content to act in harmony. Margaret's successor, Eric, the son of her niece, for whose sake she had striven to give permanence, by the act known as the Union of Calmar (1397), to the amalgamation of the three sovereignties into one, undid her glorious work with fatal rapidity, lost the allegiance and the crowns of his triple kingdom, and ended his disastrous existence in misery and obscurity. After the short reign of his nephew, Christopher of Bavaria (1440-48), the Danes exerted their ancient right of election to the throne, and chose for their king Christian of Oldenburg, a descendant of the old royal family through his maternal ancestress, Rikissa, the great-granddaughter of Waldemar II. Christian I. (1448-81), who was at the same time elected Duke of Sleswick and Holstein, was the founder of the Oldenburg line, which continued unbroken till the death of Frederick VII. in 1863. His reign was followed by half a century of international struggles in Scandinavia. The insane tyranny of Christian II. (q.v.) cost that monarch his throne and freedom; the Danes chose his uncle Frederick I. to be their king, while Sweden was for ever separated from Denmark, and rose under the Vasas (see GUSTAVUS I.) to be a powerful state.

Under Christian III. (1536-59), the Reformation was established in Denmark. Christian IV. (q.v.), after his brief share in the Thirty Years' War, proved one of the ablest of all the Danish rulers. His liberal and wise policy was, however, cramped in every direction by the arrogant nobles, to whose treasonable supineness Denmark owes the reverses by which she lost (1658) all the possessions she had hitherto retained in Sweden; and with the relinquishment of these, and consequently of the undivided control of the passage of the Sound, the country's former international importance came finally to an end. The national disgraces and abasement which followed led, in 1660, under Christian's son, Frederick III., to the rising of the people against the nobles, and their surrender into the hands of the king of the supreme power. For the next hundred years, chiefly marked by wars with Sweden, the peasantry were kept in serfdom, and the middle classes depressed; but by the end of the 18th century the peasants had been gradually emancipated, while many improvements had been effected in the mode of administering the laws, and the Danish kings, although autocrats, exercised a mild rule. The miseries of the reign of Frederick VI., who governed as regent from 1784, brought the country to the verge of ruin. Denmark having joined Russia in a compact of the Northern Powers hostile to England, a fleet was sent into the Baltic, and considerable injuries were inflicted by an attack on Copenhagen, in 1801, under Parker and Nelson. From this the country rallied; but in 1807 the British government, suspicious of an intention on the regent's part to violate his neutrality and take sides with Napoleon, demanded the surrender of the entire Danish navy, to be restored at the conclusion of peace. A refusal was followed by the bombardment of Copenhagen in September 1807, and the fleet was given up;

but this treatment drove Denmark into Napoleon's arms, and with him the kingdom was obliged to co-operate until the close of 1813.

By the congress of Vienna, Denmark was compelled to cede Norway to Sweden. From this period a spirit of discontent grew up in the duchies, degenerating into mutual animosity between the Danish and German population, which led to an open rupture with Denmark in 1848, immediately after the accession of Frederick VII. (For the whole question, see SLESWICK-HOLSTEIN.). After alternate hostilities and armistices, the war was virtually concluded in 1849, by the victory of the Danes at Idsted; but in 1863 the quarrel was renewed. On the death of Frederick in that year, Prince Christian of Sleswick-Holstein-Glücksborg ascended the throne under the title of Christian IX., in conformity with the act known as the Treaty of London of 1852, by which the succession to the Danish crown had been settled on him and his descendants by his wife, Princess Louise of Hesse-Cassel, niece of King Christian VIII. of Denmark. A pretender, backed by German influence and help, at once started up in the person of the eldest son of the Duke of Augustenborg, who assumed the title of Duke Frederick VIII. of Sleswick-Holstein; but his cause was speedily merged and lost sight of by Prussia and Austria in their direct aim of incorporating the duchies with the German Confederation. Denmark, unaided by England and France, allies on whose support she had relied, was forced to go single-handed into the unequal contest. After a brave but utterly futile attempt at resistance, the Danes found themselves forced to submit to the terms dictated by their powerful foes, and resign not only Lauenborg and Holstein, but the ancient crown-appanage of Sleswick. By the peace of Vienna, 1864, the Danish king bound himself to abide by the decision which Prussia and Austria should adopt in regard to the destiny of the severed Danish provinces. The dissensions between these two great powers, which led to the Austro-Prussian war of 1866, resulted in the triumph of Prussia, and since then the duchies have remained an integral part of that state. Since the war, Denmark, although reduced to the narrow limits of the islands and Jutland, has recovered from its fall, and has greatly prospered, in spite of the spread of socialistic opinions, and the political dissensions that have ranged the government and Landsting, supported by the press of the capital, against the Folkething and majority of the people.

For the geography and statistics, the best Danish works are those of Erslev, Trap, Grove, Falbe-Hansen, O. Nielsen, and Scharling; see also Both, *Kongeriget Danmark, en historisk-topografisk Beskrivelse* (2d ed. 2 vols. Copenhagen, 1882-85), and Miss E. C. Ott's *Denmark and Iceland* (Lond. 1881). For the history, works by Paludan-Müller, Barfod, Fabricius, Allen, and Thorsøe may be consulted, and, in English, Miss Ott's *Scandinavian History* (1875), in Macmillan's series.

DANISH LANGUAGE AND LITERATURE.—The Danish language has sprung from the south-eastern or Danish-Swedish branch of the *dönsk tunga* (or *lingua danica*), which was the common name by which the language of all the Scandinavians was designated in the middle ages by the southern races of the Teutonic stock. From the 11th to the 13th century the Danish-Swedish branch of the Old Scandinavian became more and more markedly distinct from the Norwegian-Icelandic branch, through its replacing the old diphthongs with single long vowels, and dropping the initial *h* before *l*, *n*, and *r*; while the latter became characterised by a further modification of the *a* sound, by the loss of *v* before *r*, and by a series of contractions of consonants. In the provincial laws of the 12th and 13th centuries, which (after

the Runic monuments) are the earliest specimens of this Danish-Swedish language, there are three dialects—that of Skaane (the southmost province of Sweden) and those of Zealand and Jutland, the first of which is nearest the old language, while the last two have deviated from it by dropping the final consonants from the old inflexional endings and changing their vowels *a*, *i*, *u* to a less distinct *e* or *æ*, retaining, however, the hard mutes *p*, *k*, *t* after vowels, as on the whole is still the case in Swedish and spoken Norwegian. The dialect of Zealand in the 14th and 15th centuries forms the foundation of modern Danish. The original vowels in almost all endings are there replaced by half-vowels, and the dental aspirate *þ* by *t* or *d*; *p*, *k*, *t*, when following long vowels, are changed to *b*, *g*, *d*; masculine and feminine are merged in one common gender; nouns have no other case-ending than the possessive *s* for both numbers; verbs cease to indicate person (except in the imperative); and the singular number begins to supersede the plural, as it does everywhere in the spoken language from the 16th century. Danish, like Swedish, retains the suffixed definite article, which is characteristic of the Scandinavian languages. Its form is *-et* in the neuter, *-en* in the common gender, and *-ne* in the plural of both.

The influence of the Hanseatic League and the Oldenburg dynasty (from 1448) brought in a great number of Low-German words, especially relating to navigation and trade; while that of the order of St Bridget contributed a considerable Swedish element. In the first half of the 16th century the Danish language was chiefly used by religious writers, and the translation of the Bible (1550) is the first important monument of modern Danish. After this period Latin became once more the language of learning and culture, and for a century and a half there was no Danish writer of eminence. The influence of French was predominant in the 17th century, and that of High-German, which had been constant since the Reformation, culminated in the 18th century under the Struensee administration, when it was the language of government and public instruction. The result is, that Danish is indebted to German for fully one-third of its vocabulary. It was not till Holberg that the Danish written language began to be enriched from the stores of native expression in the spoken tongue. From the end of the 18th century revived study of Old Scandinavian and the development of a national poetic literature unfolded the language in a hitherto unsuspected richness and fullness, and since that time Danish prose has to a considerable extent worked itself out of its poverty and dependence. Danish is the softest of the Scandinavian languages, though less euphonious than Swedish. It is the language of the educated class in Norway, where it is considerably augmented from the native dialect, and is spoken with a somewhat harder pronunciation. The best histories of the language are by Petersen (2 vols. Copenhagen, 1829–30) and Mollech (*ib.* 1846); grammars by Rask (2d ed. Lond. 1846), Lökke, Munch, Lynghy, Jessen, and Möbius (Kiel, 1871); and dictionaries by the Danish Academy (Copenhagen, 1793–1881), and Mollech (2d ed. 2 vols. *ib.* 1859), who also produced a *Dansk-Dialekt-Lexikon* (*ib.* 1841) and a *Dansk Glossarium* (*ib.* 1853–66) for antiquated words. Ferrall, Repp, and Rosing's Danish and English Dictionary, in 2 parts (4th ed. Copenhagen, 1873), is the best for English students.

Literature.—After the Danish dialect had gradually separated itself from the Old Scandinavian as a softer and simpler speech, with a strong infusion of German ingredients, it was little used in writing down to the time of the Reformation. Saxo

(grammaticus (i.e. 'the learned') in the second half of the 12th century wrote in Latin his *Historia Danica*, the only literary production of medieval Denmark that retains any interest. The earliest writings in Danish are the church laws of Skaane (1102) and Zealand (1170), and the civil laws of Skaane (1160), Zealand (1170), and Jutland (1241); and after these a number of chronicles, partly in verse, of which the best known is the *Rimkrönike*, which was the first Danish book printed (in 1495). It is essentially an abridgment of Saxo. The famous Danish ballads called *Kæmpeviser* ('hero-songs'), some of which are said to belong to the latter part of the 11th century, were handed down orally from generation to generation, and were first collected, to the number of 100, by A. S. Vedel in 1591. In 1695 Peder Syv published a new edition with 100 more, and in 1812–14 appeared a selection of 222, edited by Abrahamson, Nyerup, and Rahbek. The most complete collection is in Svend Grundtvig's unfinished *Gamle Folkeviser* (5 vols. 1853–77). They are about 500 in number, and treat of the adventures of heroes, love, enchantment, spectres, and historical events. Doubtless they were sung to the dance, as is still the case in the Farøe Islands. They must have suffered much by their not being written down till the 16th and 17th centuries.

The Reformation only emancipated Danish culture from Latin to bind it fast to German, which at the death of Frederick I. in 1533 was the language of the upper classes. About that time Christian Pedersen set up a printing-press at Malmö, at which he published a great number of popular books, and finally in 1550 the first complete translation of the Bible. Pedersen (1480–1554) is justly called the father of Danish literature. The hymns and translations of the Psalms by his contemporary Tausen (1494–1561), as also by Kingo (1634–1703), Vormondsen (1491–1551), and Arrebo (1587–1637), and the national history (10 vols. Copenhagen, 1595–1604) of Hvítfeld (1549–1609) were well received; but the Danish language was still banished from higher society till the advent of the Norwegian Holberg (1684–1754), the founder of Danish comedy. He found Denmark on the point of being absorbed in Germany. 'The common people,' he says, 'had no histories but dry lists of dates; no poetry but congratulatory verses; no theology but homilies and funeral sermons; and for plays, nothing but old stories about Adam and Eve.' He wrote histories of Denmark, of the Jews, and of the Church; and the irresistible humour of his comedies and satires covered with ridicule the imitations of foreign speech and manners. What Holberg did for Danish prose, another Norwegian, Tullin (1728–65), did for Danish poetry. Equally dissatisfied with the current imitations of the 17th century court-poetry of France, and with the poetic reform of Klopstock (at Copenhagen from 1751), Tullin followed the guidance of the English poets Pope, Young, and Thomson, and in this was followed by most of his countrymen who were settled at Copenhagen, while the Danes clung to German models. Ewald (1743–81), an ardent disciple of Klopstock, was Denmark's first great lyric poet and tragic dramatist. His verse shows an unsurpassed mastery of form, and is expressed in pure, clear, and noble language. Wessel (1742–85), by his 'tragely,' *Love without Stockings* (1772), a humorous parody of the Danish imitations of the classical French drama, succeeded in laughing them off the stage. Nordahl Brun (1745–1816), preacher and poet, Claus Frimann (1746–1829), 'the Burns of the Norwegians,' Claus Fasting (1746–81), Jonas Rein (1760–1821), Jens Zetlitz (1761–1821), and

others, formed themselves (1772) into a 'Norwegian Society' at Copenhagen, under the leadership of Wessel. It was the literary manifestation of the Norwegian aspiration to separate nationality, which afterwards led to the foundation of the university of Christiania in 1811. From the death of Wessel in 1785 to the beginning of the present century the literature became entangled in rationalistic and political polemics, and produced little that is noteworthy. Its chief writers were P. A. Heiberg (1758-1841) and Malte Konrad Brun (1775-1826), both of whom were driven into exile in 1799-1800, the latter afterwards famous as a geographer; the critic Ralibek (1760-1830); the dramatists Samsø (1759-96) and Sander (1756-1819); and the lyricist Thaarup (1749-1821).

The poet and humorist Baggensen (1764-1826) forms the link between the 18th century and the early part of the 19th, when Danish literature took an entirely new departure, partly owing to the study of Kant, Fichte, and Schelling, and the influence of Schelling's follower Steffens (1773-1845); partly also to the strict censorship of the press in force from the year 1799. The educated classes turned from their controversies on points of literary criticism and theology to scientific inquiry; and the people, whose national feeling had been aroused by the French Revolution, by the share of Denmark in the Napoleonic wars, and especially by the events of 1801 and 1807, the war with Sweden (1808), and the loss of Norway (1814), welcomed with enthusiasm the rise of a new school, led by the romantic poet Oehlenschläger (1779-1850), who was equally distinguished as a lyrical and dramatic writer, and is still regarded by many as the greatest Danish poet. Contemporary with him were the poets Schack-Staffeldt (1769-1826) and Grundtvig (1783-1872), afterwards more eminent as a theologian; Ingemann (1789-1862), long the most popular novelist of Denmark; J. L. Heiberg (1781-1860), director of the royal theatre at Copenhagen, writer of numerous vaudevilles, and of the still popular national play, *Elves Hill* (1828); Hanch (1791-1872), dramatist, novelist, and critic; and Blicher (1782-1848), who in his tales of Jutland was the first worker in the field which has since been cultivated in Germany by Jeremias Gotthelf and Berthold Auerbach. Of the other novelists of this period the chief are Brosbøll (b. 1820); Fru Gyllembourg-Ehrensverd (1773-1856), mother of J. L. Heiberg; Saint-Aubain, or 'Karl Bernhard' (1798-1865); and the still more popular Winther (1796-1876), the charming poet of Danish country life. Herz (1798-1870), from the time when his *Ghost Letters* (1830) surprised the public with a poetic revival of the muse of Baggensen, has, now with his lyric poems, now with his tales, now in romantic and national tragedies, now in comedies and light vaudevilles, provided his countrymen with artistic and attractive works. Overskou (1798-1874) is a skilful dramatist, and Hostrup (b. 1818) a popular author of comedies. All these writers are surpassed by Hans Christian Andersen (1805-75), whose wonderful stories are known throughout the civilised world. Less popular, but more profound, was the versatile writer Fr. Paludan-Müller (1809-76), who from his play *Love at Court* (1832) to his great epic poem *Adam Homo* (1841-48) has wooed all the muses in succession. Here may be mentioned Bergsøe (b. 1835), writer of novels and popular works on scientific subjects; Goldschmidt (1819-87), editor of the influential democratic journals, *The Corsair*, *North and South*, and *Home and Abroad*, and afterwards author of numerous romances; Holst (b. 1811), a writer of pleasing lyrics and tales; Kaalund (1818-85), with his two collections of poems, *A Spring* and *An Autumn*;

the erotic and piquant and sometimes frivolous song-writer Aarestrup (1800-56); and Lembcke (b. 1815), the translator of Shakespeare.

A great impulse was given to all branches of science from the beginning of the 19th century. The leading theologians were Grundtvig, the enthusiastic champion of the faith of his fathers against rationalism, and advocate of a union of the Scandinavian kingdoms, but with the church separated from the state; Mynster (1775-1850), Bishop of Zealand; Clausen (1793-1877), the disciple of Schleiermacher, and theological opponent of Grundtvig; Martensen (1808-84), Bishop of Zealand, and author of standard works on systematic theology and ethics; and Kierkegaard (1813-55), the most original thinker of Denmark. The chief exponents of philosophy were Sibbern (1785-1872), Nielsen (b. 1809), and Bröchner (1820-76); and in natural science the greatest names were those of Oersted (1777-1851), the discoverer of electro-magnetism, the botanist Schouw (1789-1852), the geologist and chemist Forchhammer (1794-1864), and the zoologist and archaeologist Steenstrup (b. 1813). Much has been done for the study of Scandinavian antiquity by the *Sagabibliothek* of Müller (1776-1834), and the researches of Finn Magnusson (1791-1846) in mythology, and of Thomsen (1785-1865) and Worsaae (1821-85) in archaeology. The chief 19th-century writers of national history have been Werlauff (1781-1871), Molbech (1783-1857), Allen (1811-77), Schiern (b. 1816), and K. P. Paludan-Müller (1805-82); and of the history of the national literature and language, Petersen (1781-1862). In philology, Rask (1787-1831) and Madvig (1804-86) have a European fame.

About 1850 the enthusiasm for the national past, which had been excited by Oehlenschläger in Denmark, and by Tegnér, Geijer, and others in Sweden, together with the hatred of Germany aroused by the war of 1848-50, rose to a pitch of fanaticism. 'The northern force which had controlled the world' was extolled by Ploug and others as 'the only means whereby the victory of the Cause of Humanity could be achieved.' After Ploug (b. 1813) the chief exponents of this great historic mission of the northern kingdoms were C. K. F. Molbech (1821-88), a euphonious lyric and skilful dramatist, and translator of Dante; and Erik Bögh (b. 1822), a fertile writer of *feuilletons* and adapter of plays. A cosmopolitan reaction set in about 1870, led by Georg Brandes (b. 1842), who proved in his lectures on literature that Denmark was only a side-chapel in the temple of European thought and art, and that this overstrained 'Scandinavianism' was but the northern phase of the reaction from the tendencies of the 18th century, which had been experienced in England, France, and Germany many years before. Brandes withdrew to Berlin for some years from the storm of popular opposition. Not only in Denmark, but in Norway and Sweden also, his followers are now the prevailing party. The most conspicuous of these have been Jacobsen (1847-85), the translator and adherent of Darwin, and author of *Mogens* (1872) and other novels; and (till in 1883 he became a Conservative) Drachmann (b. 1846). Of recent writers, the most noteworthy are Schandorph (b. 1836), who is equally happy in his sketches of the Zealand peasant and the Copenhagen snob; the versatile writer Hermann Bang (b. 1858); and the dramatist Edvard Brandes (b. 1847), brother of Georg Brandes.

Of the three Scandinavian nations, the Danes have shown the greatest aptitude for the imitative arts, and their art is comparatively the most independent. While the painters of Norway have been mostly trained at Düsseldorf, and those of

Sweden at Paris, the artists of Denmark have been especially attracted to Rome. The sculptor Thorwaldsen (q.v.) has left a great monument of his genius in the works contained in the Thorwaldsen Museum at Copenhagen. Of later artists may be mentioned the painters Marstrand, Carl Bloch, Exner, Kroyers, Henningsen, and Otto Bache. Of music, the chief composers in the 19th century have been Hartmann, Gade, and Heise.

See Nyerup and Rahbek, *Den danske Digtekunsts Historie*, 4 vols. (1800-8), and *Udsigt over den danske Digtekunst under Frederik V. og Christian VII.* (1819-28); Nyerup and J. E. Kraft, *Almindeligt Litteraturlæxikon for Danmark, Norge og Island* (Copenhagen, 1818-20); Petersen, *Den danske Litteraturs Historie*, 6 vols. (1853-64); Overskou, *Den danske Skueplads i dens Historie* (1859-74); G. Brandes, *Ludvig Holberg og hans Tid* (1884); the general treatises in Danish by Thortsen (1811; 6th ed. 1866), Heiberg (1831), Molbech (1839), Ström (1871), Erikson (Christiania, 1878), Winkel-Horn (1880), and Hansen (1884 et seq.); and in German by Strudtmann (1873), Wollheim de Fonseca (1874-77), and Winkel-Horn (1880). See also a part of Edmund W. Gosse's *Studies in the Literature of Northern Europe* (1879).

Dennery, ADOLPHE PHILIPPE, a French dramatic writer of Jewish extraction, was born at Paris on June 17, 1811. His first employment was that of clerk to a notary; but he soon became a successful dramatic author, and was so prolific that between 1831 and 1881 he produced, by himself or in concert with others, about two hundred pieces in one style or another, including regular dramas, vaudevilles, and operatic texts. One of the most successful was the drama, *Marie Jeanne* (1845). He was the creator of the now well-known Norman watering-place, Cabourg.

Dennewitz, a small village in the province of Brandenburg, Prussia, 42 miles SSW. of Berlin. Here was fought, on the 6th of September 1813, a battle in which 70,000 French, Saxons, and Poles, under Ney, were routed, after obstinate fighting, by 50,000 Prussians, under Bulow.

Dennis, JOHN, critic, was born in London in 1657, the son of a prosperous saddler. He had his education at Harrow, and Caius College, Cambridge, where he graduated B.A. in 1679. After a tour through France and Italy, he took his place among the wits and men of fashion, and brought a sufficiently rancorous pen to the assistance of the Whig party. His acquaintance with Dryden and Wycherley and other distinguished wits, as well as his native bent, made him a playwright. His plays had but little success. Of the nine, the two most famous were *Liberty Asserted* (1704) and *Appius and Virginia* (produced 1709). Pope's *Essay on Criticism* (1711) contained a contemptuous allusion to the latter, answered by Dennis next month in *Reflections, Critical and Satirical*, which was the commencement of a long and embittered feud between the poet and the critic. Pope's *Narrative of Dr Robert Norris, concerning the Strange and Deplorable Frenzy of John Dennis, an officer in the Custom-House* (1713), was a virulent, vulgar, and officious attack made on Addison's behalf, but in which that genial author, through Steele, disavowed any complicity. Dennis was poor and blind during his last years. A few weeks after a theatrical performance, got up for his benefit by Pope and some others, he died, 6th January 1734. Dennis was embroiled in controversy all his life, and his naturally impatient temper became completely soured. He made many enemies, and his name, which his own writings could scarce preserve, will live for ever in their contempt and hate. He is one of the best-abused men in English literature. Swift lampooned him, and Pope not only assailed him in

the *Essay on Criticism*, but finally 'damned him to everlasting fame' in the *Dunciad*. Yet he was no fool, and his *Advancement and Reformation of Modern Poetry* (1701) and *The Grounds of Criticism in Poetry* (1704) will still repay perusal. 'Spite of the growling of poor old Dennis,' says Mr Lowell, 'his sandy pedantry was not without an oasis of refreshing sound judgment here and there.'

Dénouement (Fr. *dénouer*, 'to untie'), a French term naturalised in England, applied generally to the termination or catastrophe of a play or romance; but, more strictly speaking, to the train of circumstances solving the plot, and hastening the catastrophe.

Dens, PETER, a well-known Roman Catholic theologian, was born in 1690, at Boom, near Antwerp. Little is known of his early life; but from the epitaph on his tomb in the chapel of the archiepiscopal college of Malines, it appears that he was reader in theology at Malines for twelve years, *plebanus* or parish priest of St Rumold's, and president of the College of Malines for forty years. He died 15th February 1775, in the eighty-fifth year of his age. The work which has rendered Dens's name familiar, even to the Protestant public, is his *Theologia Moralis et Dogmatica*. It is a systematic exposition and defence—in the form of a catechism—of every point of ethics and doctrine maintained by Roman Catholics, and is extensively adopted as the text-book of theology in their colleges. It appears to owe its popularity more to its being a handy and usable compilation than to any great talent exhibited by its author. The casuistical parts of the work have been severely criticised by Protestant moralists. An edition was published at Dublin in 1832.

Density. When of two bodies of equal bulk, one contains more matter than the other, it is said to have greater density than that other. Since weight is proportional to mass, the same numbers may be and are used to represent specific gravity and density. Lithium is the least dense metal known, its density being 0.59 if that of water be called unity. Ordinary air may be easily compressed so as to be denser than lithium. Iridium is probably the densest substance known, its density being 22.4 times that of water. Osmium, however, is very nearly if not quite as dense. The more ordinary metals stand in the following order as regards density: Aluminium, antimony, zinc, iron (wrought), copper, bismuth, silver, lead, gold, platinum.

Dental Formula. See TEETH.

Dentalium (Lat. *dens*, 'a tooth'), or Elephant's Tusk Shell, a remarkable genus of molluscs, type of a small class called Scaphopoda. The shell is tubular, like an elephant's tusk, open at both ends, and lined by an almost completely tubular 'mantle.'

Dentalium, in natural position in sand.

The animal has an indistinct cylindrical head with a mouth at its extremity, surrounded by a circle of tentacles. Two pads at the base of the head and above the foot bear ciliated contractile filaments, possibly respiratory. The 'foot' is long and divided into three at the end. The mouth includes

a rasper. There are no eyes, but an ear-sac is present. Neither heart nor gills are developed. The sexes are similar and separate. The larva is ciliated and free-swimming. The type is of much zoological interest, but its affinities are still uncertain. The animal lives with the anterior end plunged into the sand on the sea-coast, at depths of ten to a hundred fathoms. By means of the foot they can creep slowly. They feed on minute animals, and have an almost cosmopolitan distribution. The class includes two or more other genera. *D. entale* occurs off British coasts; and about forty living species are known. The genus occurs as a fossil from Carboniferous strata (or perhaps earlier) onwards. The shells are used for currency and for ornament by the Indians of the northern Pacific coast of America. See Lacaze-Duthiers, *Histoire des Dentales* (1856-58).

Dentaria, or CORAL-ROOT (both names due to knobbed root-stock), is a small genus of Cruciferae, represented in Britain by the rare *D. bulbifera*, in which the upper leaves bear Bulbils (q.v.), while the pods rarely ripen. The root-stock being pungent, was formerly dried as a remedy for toothache. *D. diphylla*, a North American species, is called Pepper-root from the same property. The name Coral-root is also applied to the orchid *Corallorhiza*, while the true Toothwort (q.v.) is *Lathraea squamaria*.

Dentex, a genus of acanthopterous fishes near perches. One species (*D. vulgaris*), the Dentex of the ancient Romans, abounds in the Mediterranean,

Dentex.

and has occasionally been taken on the southern shores of Britain. It is an excessively voracious fish, with large sharp teeth, and attains a large size, sometimes three feet in length, and 20 to 30 pounds weight. Great numbers are taken in the mouths of rivers in Dalmatia and the Levant, where they are cut in pieces, and packed in barrels with vinegar and spices, just as the ancients used to treat them.

Dentifrice. See TOOTH-POWDER.

Dentine, or IVORY, the principal constituent of mammalian teeth. See TEETH.

Dentirostres, a somewhat old-fashioned title for one of the subdivisions of singing Passerine birds or Oscines. The term, as equivalent to 'toothed-billed,' is used in opposition to Conirostres ('cone-billed') and Tenuirostres ('slender-billed'). It would include warblers, thrushes, chatterers, crows, &c., but the character is purely adaptive to the better securing of the prey and the like, and is of little significance in classification.

Dentistry, the art of the dentist, or that of treating disease in the teeth (*Dental Surgery*), and of replacing these organs when lost (*Mechanical Dentistry*). The art is a very ancient one. The Laws of the Twelve Tables (6th century B.C.) provided for the case of 'teeth bound with gold,' it being lawful in this connection to burn or bury gold with the dead person. An Etruscan skull found in 1885 had a set of animal's teeth artificially fixed in it. The dentistry of the United States has in recent times become specially celebrated.

(1) *Dental Surgery*.—The disorders to which the teeth are liable are those arising from defective development, such as imperfections in form or structure, irregularity of position, &c.; those, again, constituting diseases more properly so called, such as caries or dental decay, necrosis or death of a tooth, inflammation of the soft tissues, such as the gum, the central pulp or nerve, as it is popularly called, neuralgic affections, &c.; lastly, those arising from accidents of various kinds, such as blows, falls, and the like. For the constitution and diseases of the teeth, see TEETH.

The object of the dentist, in treating decayed teeth, is twofold: he either attempts to arrest the decay, and repair its ravages; or he removes the diseased tooth altogether. These operations, along with supplying artificial teeth when the natural ones are lost, constitute the main offices of dentistry.

Scaling.—This is a little operation, by which the accumulation of a substance termed 'tartar' is removed from the teeth. Tartar or salivary calculus is of different densities and colours, and is a deposit from the saliva. It is most frequently found at the necks of the teeth, and lodges in greatest quantity most commonly behind the lower front-teeth. Where it accumulates it is generally accompanied by absorption of the gums, whereby the necks of the teeth are exposed, and they become loosened. Its removal is effected by little hoe-shaped steel instruments, bent in a manner to reach more easily those situations in which the tartar is found. Their mode of use is by inserting the point of any one of them under the free edge of the mass of tartar, at the gum, and lifting it away from the backs of the teeth to which it is adherent. The teeth are then freed from any particles still sticking about them, and their surface smoothed by being rubbed with pumice-powder or chalk. In certain diseased conditions of the structures about the necks of the teeth, considerable purulent discharges occur, and tartar frequently becomes largely deposited.

Regulating.—The teeth of the second, or permanent or adult set, are very liable to be crowded and misplaced, one overlapping the other, or those of the upper jaw falling behind those of the lower when the mouth is closed, thus producing the prominent condition of the under jaw denominated 'under-hung.' To remedy these defects, a variety of means have been adopted by dentists; the principle upon which all of them act, however, being that of pressing the displaced tooth or teeth into the natural position. This, of course, requires that room or space should exist for them to be thus adjusted; and where this is not the case, the usual procedure is to remove one or more of the back-teeth, or any others which it is less desirable to preserve. In other cases the dental arch itself is malformed, and may be enlarged by regulated pressure so as to afford more accommodation for the teeth, as well as to improve its contour. Some considerable time is necessary to complete the regulation of misplaced teeth; and even after they have assumed their proper position, they require to be carefully maintained there, otherwise a tendency to resume their former irregularity soon manifests itself.

Stopping or Filling.—This is one of the most important and delicate operations the dentist has to perform. The first step to be taken in filling or 'stopping' a tooth, is to clear away all decayed and decaying substance. For this purpose, a number of slender digging and excavating steel instruments, termed 'excavators,' are required. The 'dental-engine' is another valuable means of preparing the cavity for filling, and acts by means of small drills and file-headed points rapidly rotating, so as to cut away what is desired of

the tooth substance. With these, the hollow in the tooth is scooped out and thoroughly cleaned. If pain be occasioned by this process, the obtunding of the tooth's sensitiveness, or 'destroying the nerve,' as it is called, had better at once be resorted to. This is performed in several ways. Where the tooth is single-fanged, as in front-teeth, the nerve, or more correctly the pulp, may be removed by passing a slender broach, or square and pointed brad-shaped, or slender serrated steel probe up into the central cavity of the tooth, with a slight rotary motion, so as to break up and remove the pulp. Where this cannot be done at once the best plan is to destroy the pulp by some caustic application, such as arsenious acid, chloride of zinc, carbolic acid, &c., carefully applied, a variety of other substances being used for the same purpose.

The cavity being properly shaped and cleaned out until its walls are of sound and hard tooth-bone, is to be well dried, and the plug of stopping-material inserted. Various substances are employed for this purpose, and the mode of using each is somewhat different. For temporary stoppings, pure gutta-percha is a serviceable material. A quantity sufficient to fill the cavity, and somewhat more, is to be gently warmed over a spirit-lamp—not in hot water—and when quite plastic is to be firmly pressed with a blunt-pointed stopping-instrument or 'plugger' into all the interstices of the hollow in the tooth—more and more being pressed in, until the surface of the plug so formed is on a level with the surface of the tooth, when all superfluous portions should be removed, and the solid plug smoothly finished. *Osteo-plastic* fillings consist of varieties of the metallic oxychlorides and phosphates. They are inserted in a soft condition into the tooth, where they harden in the course of a few minutes.

Another variety of stopping-material consists of amalgams of different kinds. Many absurd statements have been made regarding the evil effects of amalgam stoppings, but the only real disadvantage attending their use is shrinkage, and that many of them get black in the mouth, and discolour the tooth, while some that do not get black are friable, and crumble away in a short space of time. Some of those containing copper exercise a beneficial action on the tooth-bone, but darken its colour very much. The amalgam is rubbed up with mercury to a firm, plastic consistence, and carefully introduced into the dried cavity in the same way as the gutta-percha plug.

Gold-stopping is an operation of a much more complicated and difficult description. The materials used here are either gold-foil—that is, thick gold-leaf—or the peculiar form in which gold exists known as sponge-gold; or again, 'pellets' of gold made up in a soft spongy condition of various sizes ready for use. In stopping a tooth with gold, even more care is necessary in preparing the cavity than what has been already inculcated. Its *shape* and *condition* must now be particularly taken into account, and the nearer it approaches to a cylindrical form the better. Various modes of packing the gold are adopted according to two conditions in which gold exists—namely *adhesive*, where each portion can be welded to the other; or *non-adhesive*, where they are securely fixed merely by tightly wedging them together. Non-adhesive gold can be made adhesive by heating it to redness. The surface of a gold plug, formed in any of these ways, should be well consolidated by hard pressure with a blunt plugger, or lightly hammered with a suitable mallet, and the superfluous portion being removed, it ought to be burnished until it assumes a brilliant metallic lustre.

Remedies.—Many remedies, more or less service-

able, are in use for what is termed toothache—a disorder which, however, is not always one and the same in its nature. Their intention, in general, is either to destroy the nervous fibres existing in a tooth, or to narcotise and render them insensible. Among those acting in the former manner are such as creasote, arsenious acid, carbolic acid, pepsine, chloride of zinc, nitrate of silver, alum, tannin, &c.; among those acting in the latter mode are chloroform, laudanum, ether, spirit of camphor, menthol, cocaine, &c. In all cases the decayed cavity should previously be well cleaned out, otherwise the remedy employed may be altogether prevented from reaching the spot where it is intended to act.

Extraction.—This is the principal surgical operation falling to the dentist. It is performed by means of instruments adapted to the special peculiarities of the tooth requiring removal, or to the circumstances in which it exists. The great matter is, that each tooth should be extracted in accordance with its anatomical configuration; and to accomplish this of course requires an intimate knowledge of the natural form proper to each of these organs individually; without this, it is impossible to extract any tooth upon a correct principle. The tooth is grasped, as far as the instrument can be made to do so, by that portion of the root or fang which just emerges from, or perhaps which is just within, the socket; it is then loosened, not exactly by pulling, but rather by moving it in a lateral or in a rotatory manner, in strict accordance with the respective character of fang possessed; and finally, on its being thus detached from its connection with the jaw, it is, with very little force, easily lifted from its socket.

Anæsthetics are employed in the extraction of teeth in the same manner as for other surgical operations, where it is desirable to abolish pain. See **ANÆSTHESIA**. Neither ether nor chloroform should be given by inexperienced hands, nor should both the giving of the anæsthetic and the extraction be attempted by one individual on any occasion. Nitrous oxide or laughing-gas is of much service, answering all the purposes of chloroform or ether in short operations. A combination of two or more of these anæsthetics has been employed with apparent success, such as nitrous oxide with ether. Freezing the gum, the injection into it of cocaine, and other modes of inducing insensibility, local or general, have been proposed from time to time, but one after another has been abandoned as unserviceable.

(2) **Mechanical Dentistry.**—The various conditions of the mouth requiring the adaptation of artificial teeth, range from cases where only one tooth may be wanting, to those where not a single tooth remains in the jaw, above or below. Accordingly, artificial teeth are spoken of as partial or complete sets—a partial set being one for either upper or lower jaw, where some of the natural teeth still remain; a complete set being one for either jaw, where none are left, or for both jaws, when both are in such circumstances.

The transplantation of the teeth of another individual is a very old usage revived every now and again, and equally often falling into desuetude; and implantation is a recent modification of the process.

The simplest form of partial sets is what is termed a pivoted tooth. This is an artificial tooth fixed in the mouth upon the fang or root of one whose crown has been lost by decay or otherwise. The most usual mode of procedure is as follows: An artificial tooth, as near as possible to the colour and form of that to be replaced, is selected. This artificial tooth used to be the crown of a natural human tooth corresponding to that lost, but is

now one made in imitation of this, in a species of pottery-ware called *mineral teeth*. Usually this tooth is accurately fitted to the root by means of a gold pin, inserted into the open central canal existing in the root, the other extremity of the pin being attached to the substitute tooth.

Where more than one tooth is required, and occasionally even where only one is necessary, a 'plate' or 'base' is very exactly fitted either to the gum and palate as in 'suction' sets, or to the remaining teeth where they are to be the supports, more especially in what is called crown and bridge work; and to this base the artificial teeth required are fitted and fixed.

This 'base' is frequently made of gold, silver, or platinum plate, of the thickness of card-board, of vulcanised caoutchouc or vulcanite, or of celluloid—a compound of camphor and gun-cotton. An exact model of the gum and other parts upon which the plate is to rest is obtained by introducing unset Paris plaster, beeswax, or other modelling compound, softened by previous heating, into the patient's mouth, and pressing it forcibly upon those parts of which an impression is desired. On removing the wax or other substance from the mouth, Paris plaster is poured into the mould thus procured, and on its hardening, or 'setting,' this plaster-cast presents an exact counterpart of the gum. It is upon this plaster-model that all the subsequent operations are performed in fitting the artificial set.

Metallic-plate Sets.—Where the framework lying upon the gum is to be of gold or silver plate, or the like, it is necessary to procure, besides the plaster-model, a metal one. This metal-model is generally cast in zinc, gun-metal, or some such material; and a counter-model of a softer metal, generally lead, is taken from this again, so that a complete pair of dies is in this way procured. The gold or other plate, cut of a convenient size, is then stamped between the two metallic dies, until assuming the precise form desired. It is then trimmed, and any more delicate adjustments made upon it, such as fitting and soldering bands or clasps to those parts where it is to embrace any teeth remaining in the mouth. The mode of fastening the teeth to the plate varies. One kind of teeth has a tube extending along their whole length, and these are fastened by means of a pin fixed to the plate, and passing up the tube. The other kind is provided with short platinum pins, fixed in the material of the tooth during its manufacture, to which pins a piece of gold or other plate is soldered, or a mass of gold fused upon them, and this, again, soldered to the framework of the set.

Another form of these plate sets or artificial dentures is where the plate—generally of platinum—has an arrangement suited for fusing a siliceous material to it and the teeth, so as to form an artificial gum. This is termed 'continuous gum work,' and is very effective although it has its disadvantages. Sometimes vulcanite sets are mounted with continuous gum work.

Vulcanite Sets.—The first step in the manufacture of a vulcanite set of teeth is to make a pattern set in wax, with the mineral teeth fixed in the wax. This pattern set is made upon and fitted to the plaster-model, and is adjusted to the wearer's mouth precisely as if it were the set to be worn. When everything is thus prepared, a duplicate of the wax-set is made in vulcanite—the vulcanite replacing the wax, and the mineral teeth being retained as they were. The process by which the vulcanite is made to take the place of the wax consists in imbedding the pattern set in Paris plaster, so that the inclosing mould of it, thus secured, may be separable into at least two parts. On these being taken asunder, the wax of the pattern set is melted out with boil-

ing water, leaving the teeth *in situ*. The wax is then replaced by raw vulcanite, which, on the mould being reclosed, is subjected to the usual process of vulcanising.

A base which is now sometimes used is cheoplasty, or cast-metal, an alloy usually of tin and bismuth. This base is especially adapted for mouths in which the lower alveolar ridge is very flat, as its great weight tends to keep the dentine in position. The method of construction is the same, in the preliminary stages, as for a vulcanite set. After the wax has been boiled out, the two halves of the mould are placed together, and the melted metal is poured in.

Dental Appliances.—The manufacture of dental apparatus is a very large and important one, and is carried on principally in London and the United States. A great many of the most important processes are mainly due to American invention or development. Principal among these are the process of vulcanising, the dental-engine, the rubber-dam, mineral teeth, the introduction of nitrous oxide gas, and perhaps also the great improvements in the modern operating-chair. The introduction of the vulcanite base and mineral teeth has been the means of bringing the benefits of dentistry within the reach of thousands who could not afford the expense of gold and silver plates. The dental-engine is an ingenious little machine, whereby the action of a treadle, conveyed through a flexible arm, gives a rotary motion to a drill or burr, for operating in the patient's mouth. Electricity has recently been introduced as a motor for the dental-engine and other purposes.

To show how elaborately every possible requirement of the dentist is provided for by the manufacturers, we may give a few instances. Most makers offer a choice from about a hundred varieties of forceps for the extraction of teeth; the number of drills and burrs for the dental-engine provided by one maker for selection approaches three hundred; while a manufacturer in Philadelphia keeps in stock nearly six hundred varieties of the 'plugger' (instruments for stopping teeth). There is besides an equally liberal choice in excavators, scalers, &c., while the varieties in the makes of teeth are innumerable. It has been estimated that sixteen thousand ounces of fine gold are annually used for filling teeth; ten millions of mineral teeth are annually disposed of throughout the civilised world; and for the implantation of these in the mouth, independent of gold and other bases, sixteen tons of rubber are annually required.

For a more detailed account of dentistry, we must refer to the numerous and beautifully illustrated works specially devoted to the subject, such as Litch's *System of Dentistry*, Tomes's *Dental Surgery*, Taft's *Operative Dentistry*, Richardson's *Mechanical Dentistry*; with the lesser works of Coleman, Hunter, Oakely Coles, J. Smith, Sewill, Rymes, and others.

Laws as to Dentistry.—In 1878 an act entitled the Dentists Act was passed with a view of amending the laws relating to dental practitioners. In terms of this act, no one except qualified medical practitioners and those *bond fide* engaged in the practice of dentistry at the time of the act's passing can take or use the title 'dentist,' or any title signifying that he is registered, under a penalty of £20. And in future any person desiring to become a dentist must undergo a certain course of study, and have taken a degree or license. The curriculum of study and the conduct of the examination are under the regulations of the General Council of Medical Education; and various dental hospitals and schools have been established for the instruction of the dental student. The degree in

(Great Britain and Ireland is L.D.S. (Licentiate in Dental Surgery). The only foreign degrees (both American) qualifying for registration in Britain are D.M.D. (Harvard) and D.D.S. (Michigan). In 1888 there were in practice in Great Britain and Ireland 977 licentiates under the new act, and 3889 practitioners registered as having been in practice before 1878.

Dentition. See TEETH, TEETHING, HORSE.

D'Entrecasteaux Islands, since 1884 part of the British protectorate of New Guinea, lie north of the south-eastern extremity of New Guinea. With an area of 1083 sq. m., they comprise three chief islands separated by narrow channels. They are named after the French admiral and explorer, Bruni D'Entrecasteaux (1739-93), who visited these waters in 1792. His name is also preserved in D'ENTRECASTEAUX POINT on the south-west coast of Western Australia; and in D'ENTRECASTEAUX CHANNEL, separating the south of Tasmania from Bruné Island.

Denudation, in Geology, means the laying bare of underlying rocks by the removal of superficial matter, and also the process by which the earth's surface is broken up and the loose material carried away. The more important agents of denudation are wind, rain, running water (springs, underground streams, brooks, and rivers), frost, snow, ice (glaciers), the sea (waves, breakers, currents), plants, and animals. The action of wind is seen in the erosion of rocks produced by the sand and grit which in certain dry regions is swept by the winds against projecting rocks, an action often resulting in the undermining of cliffs and the downfall of rock-masses. The sand produced by the superficial disintegration of rocks is carried forward and heaped up in the form of dunes or sandhills (see DRIFT). Rain is also a potent agent of denudation, its action being both chemical and mechanical. Rocks are more or less altered and decayed, and the decomposed materials carried off in solution by rain-water. The more soluble rocks, such as rock-salt, gypsum, and limestone, readily succumb, but there are very few rocks indeed which are not more or less acted upon chemically by rain. So that in many places the rocks are thus 'weathered' to considerable depths, the decomposed crusts varying in thickness from a mere line up to many feet or even yards. The mechanical action of rain consists chiefly in the sweeping away of this disintegrated material, which often accumulates in hollows, forming what is called *rain-wash*. Running water acts also chemically and mechanically. Thus, the rain that sinks underground and rises to the surface again in springs, brings about many changes in rocks. Immense quantities of mineral matter are brought up in solution, and thus, in time, underground cavities are formed, especially in the more soluble rocks. In regions of calcareous rocks, the whole drainage is sometimes conducted underground, the ingulfed streams and rivers acting both chemically and mechanically, and giving rise to a large series of subterranean tunnels (see CAVES). The action of underground water often brings about local subsidences, falls of rock, and great landslips. The denuding action of superficial terrestrial waters is seen in the excavation of gullies, ravines, and river-valleys, one of the most remarkable examples of river erosion being the Grand Cañon of the Colorado (q.v.), which is a chasm nearly 400 miles long, with approximately vertical walls rising to a height of 4000 to 7000 feet above the bed of the river.

Frost acts with great intensity at high levels and in high latitudes, but even in temperate regions its action is very marked and productive of great dis-

tegration of rocks. Indeed, in the production of the weathered crusts of rocks, frost is hardly less active than rain. It is in arctic and mountainous countries, however, that its action is most conspicuous. The rocks under its influence are ruptured and shattered to such a degree that frequently the parent rock-masses become buried under shivered heaps of their own debris. Glaciers are likewise powerful denuding agents. They are not only instrumental in transporting the rock-rubbish which is showered down upon them from overhanging cliffs, &c. (see BOULDERS), but by means of the blocks and debris which they drag forward on their beds, they grind, furrow, and smooth the rocks over which they flow. The peculiarly muddy character of the water that escapes from the terminal front of a glacier shows how powerful this erosive action must be, for the mud carried in suspension is simply the fine flour of the rocks which has resulted from the grinding action. The sea, again, acts like a great horizontal saw, which is continually rasping away the rocks along the coast. Cliffs are in this way undermined, rock-falls take place, and the tumbled rock-masses are by-and-by pounded down into shingle, gravel, and sand, which are hurled by the waves against the cliffs, and thus ere long the latter is again undermined, and further rock-falls take place.

The chief denuding agents have now been mentioned, but the destructive action of plants and animals cannot be ignored. Thus plants aid in the demolition of rocks by sending their roots into rock-crevices and wedging the masses asunder, and hence they aid the freer percolation of water, and prepare the way for the better action of frost. Vegetation also, by attracting rain, tends to increase the flow and erosive action of streams and rivers, while its decomposition yields to rain those organic acids which so greatly increase the chemical action of that agent. The destructive action of animals, again, is seen in the weakening of rocks on a sea-coast produced by the drilling and boring of *Saxicava*, *Pholas*, &c., and by annelids, echini, and sponges. Rocks so weakened fall more readily before the battering of waves and breakers. Thus, the whole surface of the land, from the summits of mountains down to the sea-coast, is subject to denudation. Little change may be perceptible in a lifetime or even during many centuries, but an examination of the rocks shows that many thousands of feet of solid strata have been gradually removed from the surface of a country. Thus, in many districts where faults occur, no inequality at the surface betrays the presence of dislocations; the whole area has been reduced by denudation to the same level, hundreds or even thousands of feet of strata having been removed from the upcast side of the faults (see DISLOCATION). Some attempts have been made to form a rough estimate of the rate at which the general surface of the land is reduced by denudation. As the sediment of gravel, sand, and mud which a river carries down to the sea represents the actual loss sustained by the surface of the area drained by it and its tributaries, it is obvious that if we could correctly estimate the amount of sediment transported to the sea by the rivers of any given area, we should at the same time ascertain the rate at which that area is denuded. Observation has shown that this denudation proceeds more rapidly in some regions than in others, and, therefore, that the work of no individual river can be taken as a standard by which to estimate the general rate of erosion all the world over. Much depends on physical and climatic conditions, and much on the geological structure of a country and the composition of its prevalent rock-masses. Thus, the Mississippi is said to remove

from the general surface of its basin 1 foot in 6000 years, the Rhone 1 foot in 1528 years, the Po 1 foot in 729 years. To the matter mechanically suspended in the water or swept forward on the beds of rivers we have to add the matter carried in solution, which in many rivers is very considerable. Rivers like the Rhine, the Danube, the Elbe, and the Rhone, contain in every 6000 parts by weight one part of dissolved mineral substance. These rivers, therefore, carry seawards their own weight of dissolved matter in 6000 years. Thus, subaerial denudation progresses more rapidly than we should at first be led to suspect, and those geologists who have made a special study of this question do not hesitate to assert that the action of the subaerial agents of denudation is far more effective than that of the sea, for whereas the action of the latter is confined to a narrow belt of land, that of the former has no such limitation. The whole land surface is exposed to attack, and the loose material carried down to the sea far exceeds in amount the waste of the coast-line by waves and breakers. See Playfair's *Illustrations of the Huttonian Theory*, Lyell's *Principles of Geology*, Croll's *Climate and Time*, and the standard textbooks of geology.

Denver, the capital of Colorado, is situated on the South Platte River, 922 miles W. of St. Louis. It lies on a level plain, 5196 feet above the sea, beyond which rise the snow-capped peaks and deep blue shoulders of the Rocky Mountains. Denver was founded on a barren waste, dry and treeless, in 1858, and the close of the civil war saw it a rising frontier town; in 1870 the population was 4759; in 1880, 35,629; in 1888 it was estimated at 96,000. In thirty years the mining-camp had been transformed into the 'Queen City of the Plains,' with stately buildings of brick and yellow stone, and wide, shaded streets, provided with the electric light, and with horse, cable, and electric tram-cars; and it has become the meeting-point of a great network of railways, with four direct routes to the east. It has an abundant water-supply, with 50 miles of distributing mains; many of the houses are heated by steam, supplied by a company owning 5 miles of mains; and through the resident portion streams of water course past the unpaved foot-ways. The clear invigorating air and dry climate of Denver are famous; the mean annual temperature is 48° F., and the rainfall 17 inches. Among the chief buildings are the city-hall, a handsome court-house and post-office, high school (1887), Episcopal cathedral, and the state capitol (commenced in 1886), 383 feet long by 313 wide; the town has also more than sixty churches, a university, and a number of public schools. Denver is the centre of a great agricultural and mining district, and has a large trade in cattle, hides, wool, and tallow. The value of its trade in 1886 was over \$72,000,000, of which its manufactures represented one-third; and these increased by 20 per cent. in the following year. It is chiefly, however, to its position as the centre of a great mining region that Denver owes its marvellous progress; the discovery, in 1878, of the fabulous wealth of the Leadville Hills attracted capital and emigration from all parts of the continent. It has a United States assaying mint, and is an important ore market; the daily receipts of ore in 1887 averaged 584 tons, and the product of its great smelting-works was valued at \$10,000,000, while much of the machinery used throughout the state is manufactured here. See the 'City of Denver,' by Edwards Roberts, in *Harper's Magazine* for May 1888.

Deoband, a town in the North-west Provinces of India, 15 miles N. of Muzaffarnagar by rail, with

manufactures of fine cloth, and a trade in grain, sugar, and oil. More than half the inhabitants are Mohammedans. Pop. (1881) 22,146.

Deodand. A personal chattel which was the immediate and accidental occasion of the death of a reasonable creature, was, by the law of England, forfeited to the crown, in order that it might be applied to pious uses, or given to God (*Deo dandum*), as the term implies. The law of deodand was abolished by statute in 1846.

Deodar, a petty native state in the Palanpur Superintendency, Bombay Presidency, with an area of 440 sq. m., and (1881) 24,061 inhabitants. It is a flat, open plain, with sandy soil and a hot climate; there are no rivers, and the numerous ponds are not employed for irrigation. Clarified butter is the only export.

Deodar. See CEDAR.

Deodorisers are chemical substances employed for the purpose of absorbing or destroying the odoriferous principles evolved especially from decomposing animal and vegetable matter. Thus, freshly burned charcoal is a powerful deodoriser because it absorbs sulphurous acid gas, ammonia, and other odorous gases. They belong to the classes of substances known as Antiseptics (q.v.) and Disinfectants (q.v.).

Deontology (Gr. *deon*, 'that which is binding,' and *logos*, 'a discourse'), a term for the science of duty, Ethics (q.v.).

Deori, a town in Nagpur district, 40 miles S. of Sagar, and 1705 feet above the level of the sea. Pop. 7414.

Deoxidation is the term applied to the process of withdrawing the oxygen from a compound, as in the reduction of the native peroxide of iron in the smelting-furnaces to the condition of metallic iron. On the small scale, in experimental inquiries, the process of deoxidation may be carried on before the Blowpipe (q.v.), where the inner or reducing flame is essentially a deoxidising one.

Département (Fr. *département*), a term used to denote a territorial division in France. Previous to the Revolution, France was divided into provinces; but in 1790 a decree of the Assembly ordered the abolition of the old provincial divisions (34 in number), and the redistribution of the land into 83 départements. During the year 8 of the Revolution, these were increased to 98; in 1814 the Empire consisted of 130; and the war of 1870-71 reduced it from 89 to 87, including the sadly diminished department of Haut-Rhin. The départements, each presided over by a prefect, are again subdivided into arrondissements. See FRANCE.

Dephlogisticated Air. See PHLOGISTON.

Depilatories (Lat. *depilo*, 'I pull out the hair') are chemical agents employed for removing superfluous hair from the skin. They were extensively used by the ancients, but are now restricted in their employment to the face, and to the removal of the hair from the scalp in the treatment of certain diseases. They should only be used under medical advice.

Deponent, a term in Latin Grammar applied to verbs having a passive form but an active signification. They are so called because they, as it were, lay down (Lat. *depono*) or dispense with the signification proper to their form. Such verbs had all originally a reflexive meaning, like the middle voice in Greek verbs; thus, *vescor*, 'I eat,' means radically, 'I feed myself.'—*Deponent* is also used for a person who makes a Deposition (q.v.).

Deposit, a term much used in Geology, to characterise those rocks which have been formed from matter that has settled from suspension or

solution in water. Thus, sandstone and shale are rocks composed of materials which have settled from suspension in water; while stalactites and stalagmites have been precipitated from solution in water. Deposits are characterised according to the conditions under which they were formed, as marine, lacustrine, fluvial, chemical, and so forth.

Deposit, in English law, is a branch of bailments, defined by Story to be 'a bailment of goods, to be kept by the bailee without reward, and delivered according to the object and purpose of the trust.' See BAILMENT.

Deposition, the testimony of a witness set down in writing. Depositions are taken either by a judge or by a commissioner specially appointed by him for that purpose. The questions to which the depositions are answers are usually put by the legal representatives of the parties to the suit, under the control of the court or commissioner, and the answers are taken down by the clerk of court, or by a clerk specially appointed for the purpose. It is a rule in the laws of evidence of all countries that the deposition cannot be read where the witness might be himself produced, because his oral testimony is the best evidence, and secondary evidence is never admissible.

Dépôt, in its military sense, is a place where stores, horses, or men are collected before being forwarded to the regiment or corps requiring them. By the Military Forces Localisation Act of 1872, the United Kingdom was divided into seventy brigade dépôts. These were afterwards called regimental districts and re-numbered. See ARMY, Vol. I. p. 435.

Depression, or DIP. See HORIZON.

De Profundis ('out of the depths'), the first words of the Vulgate version of the 129th psalm (A.V. 130th), which is one of the seven 'penitential psalms,' and forms a portion of the liturgy of the Catholic Church, and is sung when the bodies of the dead are committed to the grave. A tender melancholy pervades the psalm, which, however, brightens at the close under the conviction that with God there is 'plenteous redemption.'

Deptford, a town on the south bank of the Thames, $\frac{1}{2}$ miles below London Bridge, but practically a part of London, and represented in its council by two members. In 1885 it was constituted a parliamentary borough, returning one member. Of the two parishes, St Nicholas, wholly in Kent, and close on the river-bank, has a rateable value of upwards of £50,000, while St Paul's parish, which is to a great extent modern and residential, stretches partly into Surrey, and has a total rateable value of close upon half a million. A royal dockyard, dating from the time of Henry VIII., was honoured by repeated visits from Queen Elizabeth, who here knighted Captain Francis Drake when he returned from his voyage round the world. It was closed in 1869. Twenty-one acres of its site were bought by the corporation of London for £94,640, and were at a further outlay of £230,000 fitted up as a foreign cattle-market. Taking the year at 365 days, sheep and cattle are killed here at the rate of 93 every hour. The Royal Victualling Yard is also here, and as a specimen of its capacity, it may be stated that within a few hours of the official notification, 1500 tons of provisions were despatched for the relief of the starving inhabitants of Paris on the capitulation in February 1871. The Trinity House Corporation have property here; and for sixteen years before his death, the Duke of Wellington as Master went in procession to St Nicholas Church with the Elder Brethren. Since

then the ceremony has been disused, and the annual celebration takes place at Trinity Hall, London. Deptford was long famous for horticulture, but the gardens have mostly been built over or used for railway purposes. There is little ship-building now; but the General Steam Navigation Company employ a great many men here, and there are large and famous marine engineering establishments. In 1888-89 the Electric Lighting Company spent hundreds of thousands of pounds in erecting buildings and laying down plant for supplying London with light. Peter the Great worked here as a shipwright. Lord Howard of Effingham, John Evelyn, author of the *Diary*, Admiral Benbow, Crinling Gibbons, Captain Fenton the associate of Frobisher, and other famous persons, lived here; and Christopher Marlowe the dramatist, was killed here, and is buried in St Nicholas churchyard. Deptford is divided from Greenwich by the Ravensbourne, and over the creek there is a bridge where formerly the *depe ford* crossed the river. The lower portions of Deptford were improved in 1888-89, at a cost of about £100,000; the upper portions, New Cross, Brockley, and Hatcham, abound in pleasant residences. The population has grown rapidly, from 27,896 in 1851 to 76,732 in 1881, and 105,000 in 1889.

Deputy, one who exercises power which properly belongs to another who has placed him in his stead. The appointment of a deputy does not free the principal from responsibility. See SHERIFF.

De Quincey, THOMAS, author of *Confessions of an English Opium-eater*, and of many volumes of essays, criticism, and narrative, was born in Manchester on 15th August 1785. His father, Thomas Quincey, was a linen-merchant with a turn for literature; his mother, whose maiden name was Penson, was a woman of superior position and culture. Of eight children, Thomas was the fifth. An elder brother of imaginative temperament exercised much influence over him; and he records that he was profoundly impressed in childhood by the death of an infant sister. His early years were spent at a mansion built by his father near Manchester, named Greenhay; there his father died of consumption in 1792, leaving his widow and family well provided for. Thomas attended school first at Salford, then at Bath grammar-school, later at Winkfield, Wiltshire, and lastly at Manchester grammar-school. He was an apt scholar; he could converse fluently in Greek at fifteen. In 1802, when he was seventeen years of age, his health failed; and as his guardians refused to remove him from school, he ran away, to wander and study in Wales. He was allowed a guinea a week; but restlessness and want of books and of social intercourse impelled him towards London. There, failing to raise money on his expectations, he underwent singular experiences and privations, related with picturesque power in the *Confessions*. Ultimately he was sent to Worcester College, Oxford, on the inadequate allowance of £100 a year. He disliked and perhaps despised the university system, and left in 1807.

It was in Oxford that De Quincey first resorted to opium to allay pain; the use of the drug for that purpose, and also as a mental stimulant, subsequently became an overmastering and lifelong habit. His mother had now settled near Bath, and at Bristol De Quincey became acquainted with Coleridge's family; and through that connection visited Wordsworth and Southey at the Lakes. In 1808 he revisited Oxford; then went back to London, where he associated with Knight, Lamb, Hazlitt, and other men of letters. In 1809, having provided himself with an ample library, he settled to a literary career at Grasmere.

Here, in 1816, he married Margaret Simpson, the daughter of a 'statesman,' one of nature's gentlewomen. They had eight children, three daughters and five sons, two of whom distinguished themselves as soldiers. For about a year (1819) he edited the *Westmoreland Gazette*, a weekly paper published at Kendal, and was an undistinguished contributor to *Blackwood's Magazine*, the *Quarterly Review*, and other periodicals, till, returning to London in 1821, his *Confessions* appeared in the *London Magazine*, and at once made him famous. His *nom de plume*, 'The English Opium-eater,' was used till he came to be known by his proper name, in writing which he assumed the Norman prefix *de*. From London he returned to his wife and family at Grasmere, but finally left Cumberland in 1828, and settled in Edinburgh; and there, or at Lasswade, near Edinburgh, with only an occasional visit to Glasgow, he lived and worked till his death, on 8th December 1859. *Blackwood's*, *Tait's Magazine*, and latterly *Hogg's Instructor*, were for upwards of twenty years the successive receptacles of his brilliant though often diffuse and discursive papers. The *Logic of Political Economy* (1844), a philosophical contribution to that study, and a romantic story or novel, *Klosterheim* (1839)—his sole and not very successful effort in regular fiction—were issued as books; all his other writings appeared in magazines.

No 'periodical' writer of the 19th century holds a like high and apparently permanent place in English literature with De Quincey. There are three collected editions of his works—one issued in America (1852-55), in 20 vols.; a second, selected from the first, and revised by De Quincey himself, in 14 vols.; and a re-arranged and augmented issue of this edition in 17 vols. De Quincey's writings range over a vast field of literary and semi-philosophical speculation and discussion; and there, as well as in his narrative, historical, critical, and biographical essays, almost faultless refinement of style and marvellous mastery of phrase are conspicuous and charming. In criticism he is original and acute, if not exhaustive or profound; in narrative he marshals facts and incidents in the most picturesque garb and order; in argument he is always subtle, and often vigorous. His playful fancy and wealth of whimsical and humorous allusion enliven almost every topic, and the daring conception and gorgeous colouring of his opium-haunted dreams are not less admirable than the pomp and refinement of the language in which he clothes those weird and wondrous visions. De Quincey is, however, often distressingly diffuse and provokingly addicted to complex involutions of phrase and statement—parenthesis within parenthesis. He is therefore at his best when those tendencies are under control, as in certain passages in the *Confessions*, or in the splendid apostrophes—examples of what he himself calls 'impassioned prose'—that glorify such papers as 'Joan of Arc.' See *Page's Life and Writings of De Quincey* (1877); *Masson's De Quincey* ('English Men of Letters' series, 1881), and selections from his works (2 vols. 1888); *Findlay's Personal Recollections of Thomas De Quincey* (1883).

Derajat, the fluvial portion of Daman (q.v.), itself a comparatively narrow strip in the Punjab, between the Suliman Mountains and the Indus, and which, when duly irrigated, is singularly fertile. It is divided into three districts, and has an area of 17,681 sq. m., and a population (1881) of 1,137,572.—**Dera Ghazi Khan**, the capital of one of the districts, is about 2 miles W. of the Indus. Pop. (1881) 22,309.—**Dera Ismail Khan**, capital of another district, is $4\frac{1}{2}$ miles W. of the Indus. Pop. (1881) 22,164.

Derayah, a town of Arabia, on the caravan route between the Red Sea and the Persian Gulf, 450 miles NE. of Mecca, was formerly the capital of the Wahabis, and had a population of 60,000 prior to 1819, when it was taken and nearly destroyed by Ibrahim Pasha. The capital was removed to Riád, 6 miles ENE.; and at present the place consists of five walled villages, built among the ruins, with about 1500 inhabitants.

Derbend, or DERBENT ('gateway'), a port and capital of the Russian district of Daghestan, on the west shore of the Caspian, 140 miles NW. of Baku. It is charmingly situated among vineyards and orchards and fields of maize and madder, on the declivity of a branch of the Caucasus, which here approaches very close to the water's edge. Derbend is surrounded by ancient walls. The upper city forms the citadel, and contains the splendid palace of the ancient khans, now the residence of the Russian governor. The harbour is inaccessible to all but small vessels; but a considerable trade is done at the four large markets held here yearly. Silk and cotton fabrics, earthenware, and weapons are manufactured, and saffron is cultivated. Pop. (1884) 14,750. Derbend was long considered the key of Persia on the north-west side. It was captured by the Arabs in 728, by the Mongols in 1220, and frequently changed hands before it was formally incorporated with Russian Caucasia in 1813.

Derby, a parliamentary, municipal, and county borough and manufacturing town, the capital of Derbyshire, on the Derwent, 92 miles SE. of Liverpool, and 129 NNW. of London. Pop. (1841) 32,741; (1881) 81,168. The Roman station of *Derwentio* was at Little Chester, a northern suburb of Derby. It was a royal borough in the time of Edward the Confessor. Many early charters were granted to the bailiffs and burgesses of Derby; but it was not till 1638 that it was placed under the jurisdiction of a mayor. It has sent two members to parliament since 1295. The tower of All Saints (1509-27) is a grand example of Perpendicular architecture, 175 feet high. The Roman Catholic church of St Mary (1835) is a good specimen of Pugin's work. The ancient chapel of St Mary-on-the-Bridge still exists. The municipal buildings are unattractive. There is a good free library and well-filled local museum, occupying handsome and suitable buildings, the gift of Mr M. T. Bass, for thirty-five years M.P. for Derby. The grammar-school is a modern erection, but was founded in 1162. The arboretum, near the central railway station, contains 16 acres of choicely planted grounds, the gift (1840) of Mr Joseph Strutt, and now always open to the public. Derby is the headquarters of the Midland Railway Company; their offices, storehouses, workshops, and engineering establishments cover a vast space of ground. Over 5000 men are in their employ at Derby. Derby being the centre of a great railway system, access to all parts of the kingdom is direct, speedy, and frequent. Its manufactures are silk, cotton, elastic web, lace, hosiery, iron, lead, shot, porcelain, marble, colours, and chemicals. Silk, one of its staple manufactures, was begun here first in England by John Lombe in 1719. The mill that he then erected still stands on an island in the Derwent. Porcelain was manufactured here by the Duesbury family from 1756 till 1814; and the Derby Crown Porcelain Company has recently revived this beautiful industry with much success. Richardson, the novelist, and 'Wright of Derby,' the painter, and Herbert Spencer, were natives; and Derby is identified with the 'Stainton' of George Eliot's *Adam Bede*.

Derby, EARL OF, a title conferred in 1485 on Thomas, second Lord Stanley, two months after Bosworth Field, where he and his family had greatly contributed to Richmond's victory. The Stanleys were descended from Adam de Aldithley, who attended Duke William to England, and whose grandson, having married the heiress of Thomas Stanley, of Stafford, exchanged the manor of Thalk in that county, which he had received as his wife's marriage-portion, for that of Stoneley, in the county of Derby, and afterwards assumed the surname of Stanley. In 1405 Sir John Stanley, who had married the heiress of Lathom, got a grant of the Isle of Man (q.v.), which he and his descendants ruled till 1736. James, seventh Earl of Derby (1606-51), fought on the royalist side throughout the Great Rebellion, and, taken prisoner after Worcester, was beheld at Bolton; his countess, Charlotte de la Trémonille, is famous for her heroic defence of Lathom House (1644) and of the Isle of Man (1651).

EDWARD GEOFFREY SMITH STANLEY, fourteenth EARL OF DERBY, was born in 1799, at Knowsley Park, Lancashire. He was educated at Eton and Christ Church, Oxford, where, in 1819, he gained the Latin Verse prize (subject, *Syracuse*). He was elected member of parliament for Stockbridge in 1820; in 1825 he married the second daughter of the first Lord Skelmersdale; and in 1826 he represented Preston, but lost his seat in 1830, on becoming Chief-secretary for Ireland under the administration of Earl Grey. A seat was soon found for him at Windsor. He took a distinguished part in the debates in favour of the Reform Bill, and signalled his Irish administration by two bold measures—one for National Education in Ireland, and another relative to the Irish Church Temporalities, which resulted in ten Irish bishoprics being abolished. The grievance of church-rates and first-fruits was also removed, and a graduated tax upon benefices and bishoprics substituted. In 1833 he became Secretary of State for the Colonies, and in the same year carried the bill for emancipating slaves in the West Indies. In 1834, being alarmed by the success of Mr Ward's motion for appropriating the surplus of the Irish Church temporalities to secular purposes, Mr Stanley seceded from the Whigs, carrying with him Sir James Graham, the Duke of Richmond, and the Earl of Ripon. In November, upon the dismissal of the Melbourne ministry, he declined to join the Peel administration, and the Stanleyites maintained an independent position for several years. He accepted, however, the colonial seals in 1841, and held them for four years. In 1844 he resigned his seat for North Lancashire, for which he had sat since 1832, and was called to the Upper House in his father's barony of Stanley of Bickerstaffe, having for ten years before borne the courtesy title of Lord Stanley, through his father's succession to the earldom of Derby. In December 1845, when Sir Robert Peel determined to repeal the corn laws, he retired from the cabinet. In 1846 he put himself at the head of the Protectionists, who, headed in the Commons by Lord George Bentinck and Mr Disraeli, waged a stout but ineffectual opposition to the free-trade measures of Sir Robert Peel. He was now regarded as the leader of the great Conservative party.

In 1851, on the death of his father, he succeeded to the earldom. In February 1852, on the resignation of Lord John Russell, he was intrusted with the formation of an administration, which was, however, displaced in December following by a hostile vote of the House of Commons condemnatory of Disraeli's budget. On Wellington's death (1852) he was elected Chancellor of the University of Oxford. In Feb-

ruary 1858, when the Palmerston government resigned on the rejection of the Conspiracy Bill, he again became First Lord of the Treasury. At the meeting of parliament in the following year, his government brought forward a measure of parliamentary reform. A hostile amendment having been moved by Lord John Russell, and carried, he dissolved parliament, and appealed to the country. When the new House of Commons reassembled in June 1859, a vote of want of confidence was carried against his government, and he resigned. He returned to power in 1866, and, in conjunction with Disraeli, passed the Reform measure of 1867. In 1868 he resigned the premiership in favour of Disraeli. His last speech in parliament was made (1869) in opposition to the disestablishment of the Irish Church. He died at Knowsley Park, Lancashire, October 23, 1869. Lord Derby was styled in his day 'the Rupert of debate,' and stood in the very first rank of parliamentary speakers. His power of invective was almost unequalled, and his vehement contentions with O'Connell on the Repeal of the Union did much to diminish the influence of the Irish agitator. Besides being an accomplished scholar, he was a keen sportsman and a popular landlord. But he cared little for office, and more than once injured the fortunes of his party by declining to form a ministry, notably on the fall of Lord Aberdeen in 1855. Lord Derby devoted the leisure of his later years to a blank-verse translation of Homer's *Iliad*, which was published in two volumes in 1864.

EDWARD HENRY SMITH STANLEY, fifteenth EARL OF DERBY, K.G., D.C.L., LL.D., F.R.S., eldest son of the above, was born in 1826, and educated at Rugby and Trinity College, Cambridge, where he took firsts in classics and mathematics. In 1848 he was elected member of parliament for King's Lynn, and in 1852 was appointed Under-secretary for Foreign Affairs in his father's first ministry. After declining to join Lord Palmerston's ministry in 1855, Lord Stanley became Secretary for India in his father's second administration (1858-59), and carried the important measure which transferred the government of India from the Company to the crown. He was Foreign Secretary in the third Derby and first Disraeli ministries (1866-68). He succeeded his father in the earldom in 1869. In 1874 he again became Foreign Secretary under Disraeli; but resigned in March 1878, when the majority of the cabinet determined to support the tottering cause of Turkey by calling out the reserves and occupying Cyprus. After holding aloof from politics for several months, he definitely joined the Liberal party in 1880, and was Secretary for the Colonies from 1882 to 1885. His administration was remarkable for his acquiescence in the occupation of the greater part of New Guinea by Germany, and of Zululand by the Boers. In 1886 he declined to follow Mr Gladstone on the question of Home Rule for Ireland. Lord Derby was Lord Rector of Glasgow University, 1868-71, and of Edinburgh University, 1875-80. His speeches on economical subjects are always profound and convincing.

Derby Day is the second day, the Wednesday, of the Summer Meeting which takes place at Epsom in Surrey, usually towards the end of May, but sometimes early in June. Upon this day, the most important on the list, and that on which the best horses run, the famous Derby stakes, instituted by the Earl of Derby in 1780, are contended for. When the first Derby was run for, there were only 36 subscribers at 50 guineas each (with 25 guineas forfeit in case of non-starters); and for the first half-century the subscribers never numbered 90; but after 1830 there was a rapid increase, and in

1879 (which completed the century) there were 278 subscribers, and the value of the stakes exceeded £7000. Subsequently the numbers diminished till, in 1888, there were only 168 subscribers, and no more than nine horses ran, while the value of the stakes was £3675. In order to increase the competitors in future, the conditions of the race were then altered. Since 1825 (when the subscription was changed from guineas to sovereigns) the fee has been £50 each, with £25 forfeit in case of non-starters; and the value of the stakes has varied with the number of subscribers. Under the new regulations (coming into operation with the Derby of 1890) there is a fixed prize of not less than £5000 for the winner, and smaller prizes for second and third; and any surplus from the entrance fees will also go to the winner. The full subscription is still £50, but there are two forfeits—viz. £10 only if the declaration of forfeit is made about eighteen months prior to the race, or £25 if made about six months before the race. The entries are made about two years before the race, when the animals are yearlings. The alteration of conditions proved attractive to racehorse owners, as the entries for the Derby of 1890 rose to 238. The Derby Day is a great English holiday. To be present at Epsom on that occasion London empties itself, and proceeds to the Downs by modes of locomotion the most heterogeneous. For hours a continuous stream of carriages, gigs, dog-carts, vans, and vehicles of every description moves tumultuously along the road to Epsom. The benches of parliament are deserted; people of every condition come in countless numbers from all districts, and huge trains arrive every few minutes at the station, bringing their thousands, until the entire Downs are covered with a vast moving mass. At the Derby in 1861, the course, which is a mile and a half in length, was gone over in 2 minutes 43 seconds—the swiftest running, by 2 seconds, ever known on that course up to that time. In 1864 the race was run in the same time, although the horses carried 3 lb. more weight than before. In 1887 and again in 1888 the race was run in 2 minutes 43 seconds, notwithstanding that 4 lb. more had been added to the weight. When the Derby was first instituted, the weights were 8 stone for colts, and 7 stone 11 lb. for fillies; but they have been raised several times, until now the colts have to carry 9 stone, and the fillies 8 stone 9 lb.

Derbyshire, an inland county of the north midland district of England, lies between Yorkshire on the north and Leicestershire on the south, and is flanked on the east by Nottinghamshire, and on the west by Staffordshire. The shire is of an irregular triangle shape, with the apex to the south; its greatest breadth is 34 miles, and its length 56; its area extends over 1029 sq. m., or 658,624 acres. Pop. (1801) 161,567; (1841) 272,202; (1861) 339,327; (1881) 461,914. Derbyshire is the twentieth of the English counties in area, and the nineteenth in population. The surface of the county is much diversified, the south being for the most part flat, the east of a varied and undulating character, but the north exceptionally hilly and rugged. The high land of the north, usually known as the Peak (which is the name of a district and not of any particular point or mountain), is the southern termination of the Pennine chain, and forms the watershed between the Trent and the Mersey. The chief summits are Kinder Scout, 2082 feet; Axe Edge, 1810 feet; Blakelow Stones, Mam Tor, and Lord's Seat, all about 1700 feet. North Derbyshire is justly celebrated for its picturesque scenery, which chiefly centres in the valleys made through the limestone by the rivers Derwent and Wye. Matlock and Buxton, where there are warm mineral springs, are the two chief places of resort.

The other chief towns are the three municipal boroughs of Derby, Chesterfield, and Glossop, and Ashbourne, Bakewell, Belper, and Wirksworth. The county is divided into six hundreds: High Peak, north-west; Scardale, north-east; Wirksworth, west; Appletree, south-west; Morleston and Litchurch, east; and Repton and Gresley, south. Derbyshire now returns nine members to parliament; two for the borough of Derby, and seven for the county, who sit respectively for Chesterfield, High Peak, Mid Derbyshire, Ilkeston, North-eastern Derbyshire, Southern, and Western. The county council consists of 80 members.

In addition to important coal-mining, chiefly in the eastern division, Derbyshire is singularly wealthy for its area in a diversity of minerals and metals; iron, lead, zinc, manganese, copper, gypsum, pipeclay and chert for potteries, marble, fluor-spar, and alabaster being all worked within its boundaries. The chief manufactures are cotton, silk, elastic web, worsted, metallic goods, porcelain and pottery, and marble-spar ornaments. Though more a manufacturing and mining than an agricultural county, Derbyshire is not undistinguished for its pastoral and corn-growing properties. The chief crops are wheat, barley, and oats. Of the total area, 78 per cent. is under crops of all kinds, bare fallow, and grass. There is much permanent pasture and large sheep-walks in the Peak district. Several dairies of repute are in the south of the county, and their produce is chiefly taken by recently established cheese-factories on the American principle. Ecclesiastically Derbyshire is now an archdeaconry of the new diocese of Southwell, and is divided into nineteen rural deaneries, and into 140 parishes. There are ruins of abbeys at Dale and Beauchief, and peculiarly fine churches at Melbourne, Ashbourne, and Tideswell. The Saxon crypt and chancel of Repton, and the churchyard crosses of Eyam, Bakewell, Hope, &c., are the oldest ecclesiastical remains. Of feudal and domestic buildings may be named the castles of Castleton, Bolsover, and Duffield, the manor-house of South Winfield (ruin), Haddon Hall, and Hardwick Hall. Chatsworth (q.v.), the seat of the Duke of Devonshire, is unrivalled. The caves and numerous tumuli or 'lows' have yielded many evidences of prehistoric and Celtic man; whilst the traces of Roman occupation are numerous. Arbelow, near Youlgreave, is the most important 'stone circle' in England next to Stonehenge. Though a turbulent county in English history, and ever taking part in all civil tumults, Derbyshire has not furnished the site of any remarkable battle nor played any special part in national affairs; its chief historic association is the retreat in 1745 of Prince Charles Edward, Derby being the turning-point in his bold but rash enterprise. The county has had its share of distinguished men, Flamsteed the astronomer, Chantrey the sculptor, and Brindley the engineer, being all Derbyshire men; in manufacture it has been pre-eminent, Lombe first establishing an English silk-mill at Derby in 1719, and Strutt and Arkwright first making English calicoes in 1773. See the Rev. J. C. Cox's *Churches of Derbyshire* (4 vols. 1876-79), and *Guide to Derbyshire* (3d. ed. 1887); and J. Pendleton's *History of Derbyshire* (1886).

Derbyshire Spar is a name given to the fluoride of calcium, or Fluor-spar (q.v.).

Dereham, EAST, a pleasant, thriving market-town of Norfolk, 17 miles (by rail 22) WNW. of Norwich. Here, in 650, St Withberga founded a nunnery. It was burned by the Danes, but afterwards refounded; and its cruciform church remains, with a detached belfry (the 'New Clocker'), a font of 1468, a good south porch, St Withberga's well,

and the grave of the poet Cowper. Bonner was a vicar, and Borrow a native. Dereham has manufactures of agricultural implements. Pop. (1851) 3372; (1881) 5640.

Derelict, a term in English law, signifying anything forsaken or left unoccupied, or wilfully cast away. So where the sea has receded from the shore, the land thus left uncovered is styled derelict. If the sea has in such case receded suddenly, the land becomes the property of the crown, but if gradually and imperceptibly, the gain goes to the owner of the adjacent lands.

A ship which has been wrecked is styled *derelict*, and this is the common use of the term. But it is necessary that the master and crew shall have abandoned the ship, without hope of recovery. The mere quitting of a ship for the purpose of procuring assistance from the shore, or other temporary cause, with the intention of returning to her again, does not make her derelict. When abandonment has occurred, the first-comers are entitled to take temporary possession of the ship, and to claim salvage, either from the owners, the lord of the manor, or other person having right to wrecks unclaimed by the owners, or in the event of no claim from the crown. See SALVAGE, WRECK.

Derg, LOUGH, the largest lake expansion of the river Shannon, between Tipperary and Galway and Clare, is 24 miles long, with an average width of 2 miles; greatest depth, 80 feet. Its surface is about 100 feet above the sea.—Another Lough Derg, in the south of Donegal county, is 3 miles by 2½, has many small isles and rocks, and wild dreary shores. Saint's Isle contains the remains of a priory. Station Island, the reputed entrance to St Patrick's Purgatory, was long the most celebrated place of pilgrimage in Ireland.

Dermatogen, the embryonic epidermis-layer of a plant embryo. See EMBRYO.

Dermatology (Gr. *derma*, 'the skin,' and *logos*, 'a discourse'), the science of the management of the skin and of its diseases. See SKIN.

Dermatophytes (Gr. *derma*, 'the skin,' and *phyton*, 'a growth' or 'plant'), vegetable growths, chiefly of the lowest Fungi moulds, &c., inhabiting the cuticle or epidermis, and giving rise to some forms of skin-disease, as Favus (q.v.), Pityriasis (q.v.), Ringworm (q.v.), &c.

Dermestes, a common genus of beetles in the section Pentamera, including several species of formidable voracity. The most familiar of these is

D. lardarius, often called the Bacon Beetle. In the open air it lives on dead animals, and is thus useful enough; but within doors it attacks bacon, cheese, dried meats, furs, cabinet collections, &c. The brown larvæ are equally voracious. The insect itself is small, covered above with close, fine, black hairs, with the exception of the root of the wing-covers, which form a yellowish-brown band with three dark spots on each side. Both adults and larvæ simulate death. Many other species are known on hides and the like. The larvæ of some forms are occasionally utilised to clean small skeletons. The neighbouring genera *Attagenus* and *Anthrenus* also work great mischief.

Dermestes lardarius.

three dark spots on each side. Both adults and larvæ simulate death. Many other species are known on hides and the like. The larvæ of some forms are occasionally utilised to clean small skeletons. The neighbouring genera *Attagenus* and *Anthrenus* also work great mischief.

Dermis. See SKIN.

Derrick, a kind of Crane (q.v.), so named after Derrick, an English hangman at the beginning of the 17th century.

Dervish, signifying 'poor,' is a Persian word (derived from a root connected with 'door,' indicating the door-to-door mendicancy of the dervish) of which the Arabic equivalent is *Fakir* (q.v.). It designates, in Mohammedan countries, a class of devotees who correspond in their various aspects with the monks, the mendicant friars, and the freemasons of medieval Europe. Some are wanderers, depending upon alms, and often demanding charity with insolence; others are settled for the most part in convents, called Tekyas or Khânkâs, where they observe special rites, or devote themselves to solitary meditation and penance; others, again, are more like freemasons—ordinary tradesmen and labourers for most of the year, and exercising their special ceremonies only on stated occasions; whilst some, again, form a class of religious entertainers, who are hired out to chant their monotonous dirge or *Zikr* at public and private festivals. They belong to an infinity of orders or brotherhoods, among which the best known are the Kâdiris (commonly known in Europe as the 'howling dervishes,' on account of their peculiar chant), founded 1165 A.D.; the Rîfâ'is (1182), formerly famous for their feats of eating glass and live coals and swallowing swords, and also for the ceremony, recently abolished, of the *Dösch*, where the sheikh of one of their sub-orders (the Sa'dîs) rode over the prostrate bodies of the faithful in the streets of Cairo; the Mevlevis (1273), or 'dancing'—i.e. whirling—dervishes; the Nakhshibendis (1319); Bektâshis (1357), whose founder blessed and named the famous corps of Janizaries (q.v.); the Jemâlis (1750); and the Kalenderis, the 'calendars' of the *Arabian Nights*, who are under a vow of perpetual tramping: the names are taken from those of their founders.

Mevlevis, or Dancing Dervishes.

The various orders have distinctive dresses, and the sheikh or pir who commands them is also distinguished from his followers by his robes. The conical cap of the Mevlevi is well known. The rites of the different orders when they meet together vary, but consist chiefly in prayers, religious dances, monotonous recitations of the name of God and of certain pious formulas. Frequently the devotees work themselves into a state of spiritual frenzy which is accompanied by extravagant, and, to the vulgar, miraculous, feats of strength and endurance, and not unfrequently terminates in an epileptic seizure. The dervishes and their performances are held in the deepest veneration by the people, and sultans have often held them in high respect, and bestowed large endowments upon their tekyas.

It is difficult to say when these religious orders took their rise. From the earliest times, pious persons in the East have held it to be meritorious to renounce earthly joys, to free themselves from the trammels of domestic and social life, and to

devote their thoughts in poverty and retirement to the contemplation of God. In this sense, poverty is recommended by Mohammed in the Koran, though monachism is distinctly repudiated. Tradition refers the origin of these orders to the earliest times of Islam, making the califs Abû-Bekr and 'Alî found such brotherhoods; but most of them are of much later date. See Lane, *Modern Egyptians*, chap. x.; Hughes, *Dict. of Islam*; D'Olsson's *Tabl. Gen. de l'Empire Ottomane*.

Derwent, the principal river of Tasmania, issues from Lake St Clair, in the centre of the island; flows tortuously to the south-east; and enters Storm Bay at Hobart by an estuary 4 miles wide, after a course of about 130 miles. Up to Hobart the Derwent is navigable for ships of any burden.

Derwentwater, a sheet of water, stretching south from Keswick, the most beautiful of the Cumberland lakes. Lying 238 feet above sea-level, and engirt by steep wooded crags and hills, it is 3 miles long by 1 broad, and 72 feet deep at the deepest. Near its foot rises Castle Head (530 feet), commanding an exquisite view; whilst at its head are the celebrated Lodore Falls and Borrowdale (q.v.). This lake is an enlargement of the Derwent River, which traverses it in its course towards the Irish Sea at Workington. It has several wooded isles, besides a remarkable Floating Isle (q.v.). Perch are the fish most plentiful in the lake.

Derwentwater, JAMES RADCLIFFE, EARL OF, one of the leaders in the rebellion of 1715, was born in 1688, and educated in France. He succeeded as third earl in 1705, on the death of his father, who had married Lady Mary Tudor, Charles II.'s daughter by Moll Davis. On the eve of the insurrection, at the close of 1714, warrants were issued on suspicion against several gentlemen in the north of England, and one, among others, against the young Catholic earl; but having been previously warned, he fled from Dilston, his seat in Northumberland, and found refuge in the cottage of one of his dependents. He soon afterwards placed himself at the head of a few retainers, under the impression that the whole body of the Jacobites either had risen, or were about to rise. From this point the history of the Earl of Derwentwater becomes the history of the Rebellion of 1715 (see JACOBITES), which ended in the disastrous encounter at Preston, where Derwentwater bore himself with the utmost heroism, but, with most of the rebel leaders, was taken prisoner, and conveyed to the Tower of London. Impeached of high treason at the opening of parliament, he was brought to trial in Westminster Hall, when he pleaded guilty, and threw himself upon the mercy of the king. His appeal was unavailing, and he was condemned to die. Every possible effort was made by his kinsfolk and friends to obtain a pardon, but their exertions were fruitless, and he was beheaded on Tower Hill, 24th February 1716. His youth and amiability, his rank and valour, combined to excite great sympathy for the hapless earl. He is the hero of a touching ballad of the day, and of *Dorothy Forster*, Mr Besant's charming romance.

Derzhavin, GABRIEL ROMANOWICZ, the great poet of the age of Catharine, was born at Kasan, 3d July 1743 (o.s.), studied at the gymnasium of his native city, and in 1762 entered the army as a private soldier. His talents and superior education soon procured him promotion. In 1791 he became Secretary of State; in 1800, Imperial Treasurer; and in 1802, Minister of Justice. He died 9th July 1816. His poetry shows a vigorous imagination and strong power of expression, though his imagery at times verges on bombast. His lyric pieces are full of fire. His noblest, as well as his most popu-

lar ode, is his *Address to the Deity*, which has been translated into the western languages. His collected works have often been republished since 1798.

Desaguadero ('channel' or 'outlet'), the name of various waters in South America, of which the principal is the Rio Desaguadero in Bolivia (q.v.).

Desaix de Veygoux, LOUIS CHARLES ANTOINE, a famous French general, was born of a good old family at St Hilaire-d'Ayat, in Auvergne, August 17, 1768. Entering the army at fifteen, in 1796 he covered himself with glory by his heroic conduct in Moreau's famous retreat through the Black Forest. Behind the ruinous fortress of Kehl, Desaix resisted the Austrian army for more than two months, only capitulating in January 1797, when his ammunition was spent. His greatest achievement was the conquest of Upper Egypt, which he accomplished in 1799, after an eight months' campaign. His own soldiers used to compare him to Bayard, while the inhabitants named him 'the Just Sultan.' Desaix returned from Egypt just in time to take part in the battle of Marengo, in which he was killed by a musket-bullet, June 14, 1800.

Desaugiers, MARC, a once popular poet, whom some critics have set above Béranger, was born in 1772. After travelling abroad, he settled in Paris, where he became a writer of songs and vaudevilles. His subjects are generally love and wine; his verse is sweet and flowing. 'He is,' says Mr Saintsbury, 'the best light song-writer of France, with the single exception of Béranger.' He died in 1827.

Desbarres, JOSEPH FREDERICK WALLET, military engineer, was born 1722 in England, of Huguenot parentage, and in 1756 sailed as lieutenant in the 60th foot for America, where he raised, and for a time commanded, a corps of field artillery. In 1757 he gained over the Indians who had captured Fort Schenectady; and at the siege of Quebec he was aide-de-camp to Wolfe, who was mortally wounded while Desbarres was making a report. He conducted the subsequent engineering operations during the conquest of Canada, and was quartermaster-general in the expedition that retook Newfoundland (1762). He made a survey of the coast of Nova Scotia in 1763-73, and afterwards prepared charts of the North American coast for Lord Howe. He was lieutenant-governor of Cape Breton (1784-1804), and of Prince Edward Island (1805-13), having attained the rank of colonel only in 1798. He died at Halifax, Nova Scotia, 24th October 1824, at the age of one hundred and two. His principal publication was the *Atlantic Neptune* (4 vols. 1777), a splendid collection of charts.

Des'cant, in mediæval music, was the art of adding a part or parts to a melody or subject. The latter being almost invariably given to the tenor, descant came to signify generally the upper part, or *air*, of a piece. See COUNTERPOINT.

Descartes, RENÉ (Latinised into RENATUS CARTESIUS), generally regarded as the father of modern philosophy, was born March 31, 1596, at the village of La Haye, near Tours. He was sent at the age of eight to the Jesuit College at La Flèche, where he soon became distinguished for his keenness of intellect, and made great and rapid progress in languages, mathematics, and astronomy. It was not long, however, before he became dissatisfied with the doctrines and method of scholasticism, and felt it impossible to acquiesce in what had hitherto been regarded as *knowledge*. The first thing that he did after leaving college, as we are informed in his treatise on Method, was to abandon books, and endeavour to efface from his mind all

that he had hitherto been taught, that it might be free to receive the impressions of truth, whencesoever they should come. In pursuance of his plan, he resolved to travel, and soon entered the army as a volunteer, serving successively in Holland, Bohemia, and Hungary. It was while he was in winter-quarters at Neuburg on the Danube (St Martin's Eve, 1619, as he himself informs us) that there first dawned upon him the principles of the new method which he afterwards applied in philosophy and for the reorganisation of knowledge generally. So in 1621 he left the army, but continued to travel as a private gentleman, with occasional residences in Paris, till 1629. In that year he retired to Holland, where he lived in great seclusion for twenty years, devoted to the elaboration of his discoveries and the publication of his chief works. In time his doctrines attracted many disciples in the land of his adoption, but involved him at the same time in bitter controversy with the Dutch theologians. These unpleasant encounters had probably their share in inducing him to accept an invitation to go to Sweden, addressed to him by Queen Christina, who desired his learned intercourse and instruction. He left Holland in September 1648, but his constitution was not able to stand the rigour of the northern winter and the exposure involved in waiting upon the queen at five every morning for an hour's philosophical instruction. He died at Stockholm of inflammation of the lungs on February 11, 1650. Sixteen years later, his body was brought to Paris, and buried in the church of St Geneviève-du-Mont. In 1819 his remains were again transferred to St Germain-des-Près, where they now rest.

The grand object towards which Descartes directed his endeavours was the attainment of philosophical certainty. The way whereby he sought to attain this end is explained in the Discourse on Method (*Discours de la Méthode*, published in 1637). This small but extremely interesting and important treatise contains a history of the inner life of the author, tracing the progress of his mental development from its commencement in early years, to the point where it resulted in his resolution to hold nothing for true until he had ascertained the grounds of certitude. The author also, in the same treatise, lays down the methodical rules by which he resolved to guide his inquiries, and by the observance of which he hoped to arrive at *absolute certainty*, if indeed it were at all attainable. The results of his inquiries are indicated in the Discourse, but are exhibited more particularly in his *Meditationes de Primâ Philosophiâ* (Amst. 1641), and the *Principia Philosophiæ* (Amst. 1644). Doubt, according to Descartes, is the philosophic starting-point, the solvent which we must bring to bear upon all our inherited beliefs and opinions. This doubt is to be distinguished from scepticism, which is a permanent state of mind and involves despair of truth. It is to be regarded simply as an instrument of philosophical inquiry, and as such has received the name of Cartesian doubt. Applying this test relentlessly to all that had hitherto borne the name of knowledge, Descartes found one, and only one proposition that seemed to him to stand firm, and of which the truth could not possibly be doubted: that proposition was that he existed, which he inferred from the fact of his possessing consciousness. He could not doubt that he felt and thought, and therefore he could not doubt that *he*, the feeler, the thinker, existed. This relation between consciousness and existence he expressed by the memorable words: *Cogito, ergo sum*. On inquiring further into the ground of his certitude in the case of this proposition, Descartes was able to assign no further reason than that he saw very clearly that in order to think, it is necessary to exist.

He formulated, therefore, the following criterion of certainty—that *whatever is clearly and distinctly thought, must be true*. Amongst these clear and distinct thoughts he soon recognised the idea of God as the absolutely Perfect Being. This idea, he reasoned, could not be formed in our minds by ourselves, for the imperfect can never originate the perfect; it must be *connate*—i.e. part of the original structure of our understanding, and implanted there by the Perfect Being himself. Hence, from the existence of the idea of perfection, Descartes inferred the existence of God as the originator of it; he inferred it also from the mere *nature of the idea*, because the idea of perfection involves existence. The latter is known as the ontological argument, which Descartes thus reintroduced into modern philosophy. But if God exist, then we have a guarantee, according to Descartes, of the previously determined ground of certitude, for God the Perfect Being cannot deceive, and therefore whatever our consciousness clearly testifies may be implicitly believed.

The most general fundamental principle of the philosophical system of Descartes is the essential difference or dualism of spirit and matter—the thinking and the extended substances—a difference so great, according to Descartes, that they can exert no influence upon each other. Mind or spirit is pure consciousness, and matter is mere extension; these attributes are mutually exclusive, and hence these two 'created substances' can be united (as we find them, for example, in the human being) only through the intervention of the infinite substance or God. This doctrine led directly to the system called *occasionalism*, the principle of which was that body and mind do not really affect each other, God being always the true cause of the apparent influence of one on the other. A volition on our part is merely the *occasion* of God's producing a corresponding bodily motion, and similarly the material processes in the nerves and brain are only the occasion, not the cause, of the ensuing mental result. This doctrine was further developed by Leibnitz in connection with his doctrine of pre-established harmony (see LEIBNITZ). The human body being thus a mere machine accidentally united to a rational soul, it was an immediate consequence of the Cartesian doctrine that animals (in which the rational soul is absent) are literally automata; their cries no more imply feeling than the creaking of a machine. This ruthless product of logical consistency unfortunately led to cruelty in practice.

Descartes did not confine his attention to mental philosophy. His philosophy is in fact only the introduction to an elaborate system of physics. In this department it is noteworthy that he completely discarded final causes and proposed to himself the explanation of all physical phenomena from matter and motion. His celebrated theory of vortices, devised to explain the motions of the heavenly bodies, held the field till it was superseded, after a stubborn resistance, by the Newtonian theory of gravitation. It was in mathematics, however, that Descartes achieved the greatest and most lasting results. It was Descartes who first recognised the true meaning of the negative roots of equations; and we owe to him the theorem, which is called by his name, that an equation may have as many positive roots as there are changes of sign in passing from term to term, and as many negative roots as there are continuations of sign, and not more of either kind. He gave a new and ingenious solution of equations of the fourth degree; and first introduced *exponents*, and thereby laid the foundation for calculating with *powers*. He showed, moreover, how to draw *tangents* and *normals* at every point of a geometrical curve, with the exception of mechanical or transcendental curves; and what perhaps was his highest

merit, he showed how to express the nature and the properties of every curve, by an equation between two variable co-ordinates; thus, in fact, originating *Analytical Geometry*, which has led to the brightest discoveries. Editions of Descartes' collected works were published in Latin in 1697 and 1713, and in French by Cousin in 1824-26. His chief philosophical works have been translated into English by Professor Veitch. See Millet, *Descartes, sa Vie, ses Travaux, ses Découvertes* (2 vols. 1867-71); Kuno Fischer, *Descartes and his School* (Eng. trans. 1887); and English works by W. Cunningham (1877), Lowndes (1878), Mahaffy (1880), and Martineau (1885).

Descent of Man. See MAN, DARWINIAN THEORY.

Deschamps, EUSTACHE, a French poet, who was born at Vertus, in Champagne, in 1328. He was educated at Orléans University, and was in the course of his life a soldier, a magistrate, a court favourite, and a traveller in Italy and Hungary. He held several important posts in his native province, but his possessions were ravaged by the English, and he seems to have been a poor man when he died in 1415. He was both a popular and voluminous writer. He composed 1175 *ballades*, a multitude of *rondeaux*, *virelais*, and other lyrics, besides a long poem of 13,000 lines, entitled the *Miroir de Mariage* - his works in all amounting to more than 100,000 lines. Deschamps was an ardent patriot, in whose verse hatred of the English and of the native oppressors of the French poor finds repeated and bitter expression. His thought is, as a rule, grave and dignified, but his style is somewhat wanting in elegance and ease. Occasionally, however, as in his lament for Du Guesclin, his verse is both graceful and touching; and in one at least of his pieces, an apologue exposing the exactions of the rich, he gives proof of a grim and trenchant satiric faculty. The edition of his *Poésies Morales*, edited by M. Crapelet (1832), is superseded by the complete edition for the Old French Text Society by the Marquis de Jueux de Saint-Hilaire. See Walter Besant's *Early French Poets* (Macmillan, 1868).

Deseret. See UTAH.

Desert (literally, 'a solitary place') is the geographical name applied to a barren and uninhabitable portion of the earth's surface. Four classes of desert may be distinguished.

(1) *Ice-wastes* occupy the central plateau of Greenland, the islands of the Arctic Sea, and probably the entire Antarctic continent. The ground is covered to an unknown depth by a vast ice-cap, rough and hummocky on the surface, and moving onwards to the coasts in a continual procession of glaciers.

(2) *Tundras* are flat plains, little elevated above sea-level, fringing the Arctic shores of the northern continents, and specially characteristic in Siberia (q.v.). The soil remains frozen to a great depth all the year round, thawing superficially when the snow melts in summer, and becoming covered with coarse moss and dwarfed Arctic plants.

(3) *Arid wastes*, or deserts in the popular sense of the word, occur mainly in two zones encircling the world, and corresponding to regions of minimum rainfall (see CLIMATE). The more extensive extends from near the equator in an east-north-east direction across the whole breadth of North Africa, as the Great Sahara, Libyan and Nubian deserts, over the peninsula of Arabia, through Persia, Turkestan, the Gobi or Shamo Desert, in about 52° N. lat., to the Pacific Ocean (see ASIA). The great Indian Desert in the Punjab is the

only extension of this belt south of the Himalayas. The ring is completed by the Great Basin of North America in 40° N. lat. The southern zone, less complete, comprises the Kalahari Desert in south-west Africa, the interior of Australia, and small districts in the Argentine Republic and in the Andes. Deserts occur at all elevations, from considerable depths beneath sea-level to many thousand feet above it, and with all varieties of surface, from a flat expanse of sand, where the view for days of travel is bounded by a sharp circle as at sea, to rocky mountain-slopes rent by rough defiles all bare and chiselled by the driving sand. The essential character of an arid waste is its rainlessness, and the scarcity of water on the surface and of water-vapour in the atmosphere. Radiation in the clear air is intense, and desert climate is consequently of an exaggerated continental type. The sand in the Sahara becomes heated to over 150° F. during the day, and chilled below the freezing-point at night, while the diurnal and seasonal extremes in the lofty deserts of Central Asia are much greater. Thus desert-regions are most effective in producing land and sea breezes and monsoon winds in consequence of the marked periodical changes in atmospheric density. Another effect is the *Mirage* (q.v.), a phenomenon which, combined with the indescribable horror of loneliness that oppresses the occasional traveller, probably accounts for the widespread superstitions peopling deserts, above all other places, with evil and malicious spirits. The dreaded sand-storm or simoom is a kind of tornado or whirlwind which raises the sand in tall rotating columns sweeping over the surface with tremendous velocity. Sand-dunes, sometimes several hundred feet in height, are raised by steady winds, and gradually shift their position, extending the bounds of the desert to leeward. Desert vegetation is extremely scanty, consisting mainly of hard prickly plants of the cactus, euphorbia, and spinifex kinds, whose glazed surface exhales little of the hardly-won moisture. Animal life is correspondingly restricted both in variety and number of individuals. The Camel (q.v.) is *par excellence* the beast of burden for conducting traffic across arid wastes. When an overflowing river, such as the Nile, traverses a desert, the land becomes richly fertile in its immediate neighbourhood, and wherever a spring bubbles up through the sand there is an Oasis (q.v.) bearing palm-trees and grass. Artificial irrigation, especially the sinking of artesian wells, has done much to reclaim tracts of desert for agriculture in the Sahara (see ALGERIA), and to a less extent in Australia.

Geological considerations show that arid deserts are not permanent features of the earth's surface. The most level expanses have once formed part of the ocean-bed, or at least great inland seas. The orographical changes which cut off these seas and created inland drainage areas probably at the same time modified the rainfall of the locality. Excessive evaporation dried up the great lakes, leaving at present a series of diminishing salt lakes without outlet, receiving rivers which dwindle down by evaporation as they flow. The only commercial commodities yielded by deserts are the salts (common salt, borax, sodium carbonate, and sometimes sodium nitrate) left in the dried-up lake-beds. These salt lakes are subject to alternate long periods of desiccation and flooding; during the former the area of the desert extends, during the latter it contracts. These periods have been traced out in the case of the Great American Basin by a series of most interesting researches on the part of the United States Geological Survey.

(4) *Temporary deserts*, or steppe-lands, border the Asiatic deserts to the north and west. The saline steppes of the Caspian are true arid wastes;

but the typical steppes in South Russia are luxuriantly clothed with verdure and flowers in spring. In summer they form a dusty plain of withered herbage, and in winter are wind-swept wastes of snow. The grassy *llanos* of the Orinoco present a similar desert appearance in the dry season; in the wet season they are inundated marshes which burst into blade and bloom as the water subsides. The *pampas* of the Plate river-system under similar but less marked seasonal changes form a natural transition to the fertile prairie lands which, although naturally treeless, are always richly grassed.

Desertas, a group of three rocky islets in the Atlantic Ocean, to the SE. of Madeira, visited at certain seasons of the year by fishermen and herdsmen.

Desertion from the army or navy is the crime of absence without leave, coupled with the intention of not returning to the service, or of avoiding some important duty, such as embarkation for a foreign station or aiding the civil power, however short the time of absence or the distance to which the absentee may have gone. Under the Army Act of 1881 the very common offence of quitting one regiment to join another (formerly charged as both 'desertion and fraudulent enlistment'), inasmuch as it proves no intention to leave the service, is punishable by Court-martial (q.v.) as fraudulent enlistment only, but in the same way as desertion when not on active service—viz. by imprisonment up to two years for a first offence, and penal servitude for not less than five years for a second or subsequent offence, together with forfeiture of service, medals, &c., to which may be added stoppages of pay for loss of kit, and discharge with ignominy. By thus distinguishing between desertion and fraudulent enlistment, the number of soldiers annually convicted of the former crime has been reduced by one-half; short service, the abolition of Bounty (q.v.) on enlistment, and better education have had the effect of still further reducing this number. It is still, however, large (about 3000); and, beyond a published description of all absentees and deserters, recruiting officers have no means—such as formerly existed, when tattooing with the letter 'D' (erroneously called Branding, q.v.) always formed part of the sentence—of detecting a man who has been convicted of this crime and discharged with ignominy, or who endeavours to fraudulently re-enlist. Thus individual men often join five or six regiments, deserting immediately from each in turn and selling their kits, which cost the country some £4 or £5 each. When apprehended considerable further expense is incurred in bringing them to trial and maintaining them in prison.

Desertion, or attempting to desert, when on active service, or under orders for active service, is much more rare, and is punishable with death. So is the crime of inducing a soldier to desert under those circumstances; and a civilian who is convicted of it, if subject to military law because accompanying a force in the field, as a newspaper correspondent or a camp-follower, is liable to this punishment. When not subject to military law, six months' imprisonment with hard labour may be awarded by any court of summary jurisdiction to a civilian who induces or assists a soldier to desert. Deserters from the United States army forfeit all pay and allowances due at the time of desertion. If in time of war, the penalty is death; in peace, they suffer such penalty as a court-martial may direct.

Desertion is equally a crime when committed by a seaman of the royal navy. A sailor absent from three successive musters is a 'runaway'; and when discovered and brought back, he is punished by a

deduction from his pay. If his absence is continued, it amounts to desertion. All harbouring of deserters by other persons is punishable. In the navy of the United States, a temporary absence without leave with an apparent intention of returning to duty, is regarded as 'straggling,' but an absence of ten days constitutes desertion. In either case the commanding officer decides the points, and causes the proper entries to be made on the ship's books.

Desertion of the Diet. See DIET.

Desertion of Wife and Children. See HUSBAND AND WIFE, PARENT AND CHILD.

Desiccants, in Medicine, are substances with astringent properties, which are serviceable in checking secretion and exhalation.

Desiccation is the process of drying by the employment of heat, dry air, or chemical agents which have an affinity for water. Examples of the class of *desiccants* or drying substances are fused chloride of calcium, quicklime, fused carbonate of potash, and oil of vitriol. The latter is employed by being placed in a separate vessel near the substance to be dried, and under a bell jar.

Not a few of the lower animals are said to be able to endure drying up without losing the power of recovery. Some of the Protozoa form protective sheaths or cysts from which they emerge on the return of moisture. Nematodes or thread-worms (paste-eels) have been known to revive after fourteen years' desiccation, but trials beyond this limit were unsuccessful. With those animals the interesting fact has been noticed that the longer the period of desiccation, the longer the time required for recovery. Rotifers are also described as reviving after prolonged and thorough desiccation, but experiments have shown that, in the case in question at least, only the associated eggs retained their life. The eggs rapidly developed on the return of moisture, but the adult organisms proved to be really dead. The bear-animalcules or Tardigrades have been thoroughly desiccated and even heated to a high temperature without, it is said, losing power of revivification. A state of latent life is also assumed in consequence of cold, absence of stimulus, &c., and a relative quiescence occurs naturally in hibernation, or pathologically in trance. Among the lower plants, resting spores, &c., may survive desiccation; and, among the higher, seeds are well known to have a similar power. See HIBERNATION, INSECTS, LATENT LIFE, MUD-FISHES, MUMMY-WHEAT, ROTIFERS, TARDIGRADA, THREAD-WORMS, TRANCE.

Design, SCHOOLS OF. See ART INSTRUCTION, and EDUCATION.

Desira'de, a small island of the West Indies, belonging to France, and lying 4 miles E. of Guadeloupe, with an area of 10 sq. m., and a population of about 1600, engaged in fishery and the cultivation of cotton.

Desman. See MUSK RAT.

Desmids (*Desmidiæ*) are a group of conjugate Algae (see ALGÆ) related to diatoms, but readily distinguished from these by their bright green instead of brownish-yellow colour, their cellulose instead of silicified walls, and their general form, which is usually more or less deeply constricted in the middle line. As with diatoms the lower forms are, however, united in long chains, so indicating a relationship to the lower and filamentous Conjugate (Spirogyra, &c.). About four hundred species have been described, but these are often variable and ill defined. All are inhabitants of fresh water, but chiefly occur in the standing pools of heaths and peat-mosses. They rarely form large aggrega-

tions; but usually occur associated with filamentous algae, diatoms, and other forms of microscopic life. On account of the singular beauty of their general form they are much prized by the microscopist; their mode of division, too, is remarkable, yet akin to that of diatoms, the two halves of the cell being pressed apart at the median constriction

Desmids (mostly $\times 100$):

a, Continuous filament of *Spherozosma verbebratum*; b, *Micrasterias rotata*; c, *M. denticulata*, dividing; d, Zygospore of the same; e, *Closterium lunula*; f, *Closterium* in conjugation.

by the development of two new bud-halves to complete them (see fig.), two new desmids being thus gradually formed, which become as symmetrical as the original one, yet with the two apparently similar halves of very unequal age. Conjugation also occurs, with formation of a resting spore; the cyst of which may have peculiar markings or hook-like prominences. See Ralfs' *Desmidea*; *Micrographic Dictionary*, &c.

Desmodium Gyrans. See TELEGRAPH PLANT, and PLANTS (MOVEMENT OF).

Des Moines, the capital and largest city of Iowa, is situated on the Des Moines River, at the mouth of the Raccoon River, 174 miles W. of Davenport by rail. The river, which rises in the SW. part of Minnesota, flows generally SE. through Iowa, and enters the Mississippi at the SE. extremity of the state, after a course of about 550 miles. Founded in 1846, the city has a fine state-house (\$3,000,000), a marble post-office and courthouse, a Baptist university, and a state library containing over 22,500 volumes. Half-a-dozen bridges over the two rivers connect the different parts of the town, and there is a public park, with fine groves of forest trees. The town contains several foundries and planing and flouring mills, besides manufacturing of machinery, engines, boilers, railway cars, &c. Pop. (1870) 12,035; (1880) 22,408; (1885) 32,469.

Desmoncus, an American genus of climbing palms which represent the rattans (*Calamus*) of East Indian forests.

Desmond, EARLS OF, a line formerly all-powerful in the south-west of Ireland, numbered fifteen of the title, dating from 1329, and ended with that Fitzgerald who rebelled against Elizabeth's government, sacked Youghal by night and murdered the people, and was proclaimed a traitor in 1579. He escaped the fate of the Spanish garrison at Smerwick (1580), and carried on the struggle for some time; but driven at last from his strongholds, he wandered about for over two years,

and was finally killed, in 1583, in a cabin in the Kerry mountains, where his hiding-place had been betrayed to the English.

Desmoulins, CAMILLE, a famous figure in the French Revolution, was born 2d March 1760, at Guise, in Picardy. He studied law along with Robespierre at the Collège Louis-le-Grand, in Paris, but never practised owing to a stutter in his speech. His mind early became filled with lofty but confused notions of classical republicanism, which found vent on the eve of the Revolution in his pamphlets, *La Philosophie au Peuple Français* (1788) and *La France Libre* (1789), the latter published the day after the insurrection which destroyed the Bastille, in promoting which its author played a conspicuous and dramatic part. His next writing was the brilliant and vigorous *Discours de la Lanterne aux Parisiens*, which procured him the sinister title of 'Procureur-général de la lanterne.' In November 1789 he issued the first number of the *Révolutions de France et de Brabant*, which appeared weekly until July 1792 (No. 86), and which for combined brilliancy of wit and irony, polemic force, power of sarcasm, and grace of form, remains without an equal in the whole range of journalism. His next paper, the *Tribune des Patriotes*, died in its fourth number. Camille had been a member of the Cordeliers' Club from its foundation, and early clung to the mighty Danton in an affectionate friendship of singular intensity. Elected by Paris to the National Convention which followed immediately after the march of the mob on the Tuileries (August 10), he voted with his party for the death of the king. In the struggle between the Girondists and the Mountain he took an active part, and in May 1793, urged on by Robespierre, published his truculent *Histoire des Brissotins*, with a gay heedlessness which had a terrible success, and caused him soon afterwards the most profound remorse. Danton himself had thundered against the Girondists, who made a fatal error in insisting upon the ineffectual impeachment of Marat, but his great heart filled with pity when their heads fell under the guillotine of the relentless and triumphant Mountain (October 1793). On the 5th December of the same year came out the *Vieux Cordelier*, a thrilling and eloquent expression of Camille's and Danton's longing for clemency. Robespierre, at first favourable, took fright at the reception of the papers after the third, and abandoned his old fellow-student to a fate of which his fragments of writings, as well as his letters and his young wife's journals and scrap-books, show us he had already a strange presentiment. It was only in December 1790, after three years of love, that her father had permitted him to marry the bright young Lucile Duplessis, a girl of a fanciful and romantic temperament, then hardly twenty years old. Their brief married life was one of singular happiness, and in their deaths they were hardly to be divided. Meantime Hébert and his party assailed him, and his freedom of wit made fatal enemies of Billaud-Varennes and Saint-Just. The last number of the *Vieux Cordelier* that appeared in its author's lifetime was the sixth (February 1794). Already he had been twice accused before the Jacobin Club, when on the night of the 30th March 1794 he was arrested with Danton and a group of their friends and partisans. When formally asked his age before the Revolutionary tribunal, he replied: 'J'ai l'âge du sans-culotte, Jésus, c'est-à-dire trente-trois ans, âge fatal aux révolutionnaires.' Camille's sensitive temperament could not face death with the boisterous heroism of the Titanic Danton. But on the scaffold he recovered the courage that had deserted him in the prison and on the tumbrel. 'Thus then,' he said, as he looked at the blood-stained guillotine, 'the first apostle of

Liberty ends;' and with the words, 'Oh my poor wife!' he laid his head under the fatal knife. A fortnight later Lucile followed him to the same doom, dying with the heroic courage of the martyr. Their story is nobly told in Jules Claretie's *Camille Desmoulins and his Wife* (trans. by Mrs Cashel Hoey, 1876).

Desna, a river of Russia, rising in the province of Smolensk, and flowing south-eastward to Briansk, and then south-westward till it falls into the Dnieper, almost opposite Kiev. It has a course of 550 miles, navigable nearly throughout, and is the channel of a large trade; its low banks are frequently inundated in spring. Its chief affluents are the Seim and the Snov.

De Soto, FERNANDO, Spanish discoverer, born at Jerez de los Cavalleros, in Estremadura, about 1496, of a good but impoverished family, accompanied Pedrarias Davila to Darien in 1519, served on the expedition to Nicaragua in 1527, and afterwards assisted Pizarro in the conquest of Peru, returning to Spain with a fortune of 'an hundred and fourscore thousand ducats.' Charles V. now gave him permission to conquer Florida at his own expense, and appointed him governor of Cuba; and in 1538 he sailed from San Lucar with a richly equipped company of 600 men, 24 ecclesiastics, and 20 officers. The fleet anchored in the bay of Espiritu Santo (now Tampa Bay) on 25th May 1539; the ships were sent back to Cuba, and the long search for gold was begun. For three years, harassed by hostile Indians, lured onward by reports of wealth that lay beyond, the ever-decreasing company continued their toilsome march over a route that cannot now be very clearly traced. In 1541 the Mississippi was reached and crossed, and the third winter was spent on Washita River. Returning to the Mississippi in the spring, De Soto, worn out by disappointments, died of a fever on its banks in June 1542; and that his death might be concealed from the Indians, his body, wrapped in a cloak, was lowered at midnight into the waters of the great stream he had discovered. In the following year his companions, reduced to half their original number, sailed down the river in seven frail boats, and finally reached the town of Panuco, in Mexico. See his *Life* by Wilmer (Phila. 1858).

Despard, EDWARD MARCUS, conspirator, was born in Queen's County, Ireland, in 1751, and at fifteen obtained an ensigncy. From 1772 till 1790 he did good service in the West Indies, both as a soldier and as superintendent of the new territory of Yucatan. He was then recalled on the most frivolous charges, which for two years were kept hanging over him; nor, when they were dismissed, could he get the least compensation. His complaints brought him two years' imprisonment (1798-1800), on his release from which he engaged in a crackbrained conspiracy to assassinate the king and to seize the Tower and Bank of England. For this, with six of his associates, he was drawn on a hurdle, hanged, and beheaded, 21st February 1803. —His brother, JOHN DESPARD (1745-1829), British general, was present at twenty-four engagements, mostly during the American War of Independence.

Despenser, HUGH LE. See EDWARD II.

Des Périers, BONAVENTURE, one of the most interesting prose-writers of the Renaissance period in France, was born at Autun in Burgundy about the year 1500. Little is known regarding his life beyond the fact that he was a member of the court of men of letters assembled by Marguerite of Navarre. In 1537 he published the *Cymbalum Mundi*, a work in dialogue, in which, under the pretence of attacking the superstitions of the

ancients, he satirised the religious beliefs of his own day. The book raised a storm of indignation, against which Marguerite seems to have been powerless to shield Des Périers, who, rather than fall into the hands of his persecutors, is said to have killed himself in 1544. His *Nouvelles Récréations et Joyeux Devis* were published in 1558. They consist of 129 short stories, both comic and romantic, and are admirable examples of narrative art, though the laxity of the Renaissance is frequently apparent in the writer's choice of subjects. The style is vivacious and elegant; indeed, Des Périers is one of the greatest masters of French prose whom the 16th century produced. Besides writing the *Cymbalum Mundi* and the *Joyeux Devis*, it is now generally regarded as beyond doubt that Des Périers was, to a great extent at least, the author of the *Heptameron* associated with the name of Marguerite of Navarre. See the edition of Des Périers' works by Lacour (2 vols. Paris, 1866).

Despoblado (Span., 'desert'), a treeless, uninhabited plateau, nearly 10,000 feet above the sea, on the Bolivian and Argentine frontier, to the north-east of Antofagasta.

Despot. See TYRANT.

Dessalines, JEAN JAKUES, emperor of Hayti, was born about 1758 in Guinea, Africa, and was at an early age imported thence into Hayti as a slave. He was bought by a French planter, whose name he afterwards assumed, and early became a prominent leader in the insurrection, second only to Toussaint L'Ouverture. In the struggle with the French he was always distinguished by his agility and swiftness of movement, as well as by his fearlessness and ferocious cruelty. After the first compromise he became governor of the southern part of the island, but soon began the war anew, and, after infamous cruelties, compelled the French to evacuate the island in October 1803. He was created governor in January 1804, when the people of the island declared themselves independent, and on 8th October had himself crowned as emperor of Hayti, under the name of Jean Jacques I.; but his despotism, debauchery, and cruelty soon alienated from him the sympathy and support even of those who were formerly his firmest adherents. In 1806, while trying to repress a revolt, he was cut down by Christophe (q.v.), who succeeded him as emperor of Hayti.

Dessau, a town of North Germany, capital of the duchy of Anhalt, is situated on the left bank of the Mulde, not far from its junction with the Elbe, 70 miles by rail SW. of Berlin. It is in general well built. Among the principal buildings are the ducal palace, a noble structure, built in 1748, and improved in 1875, with a valuable picture-gallery and library; a town-hall, an elegant theatre, and several churches. The *Philanthropinum* of Basedow (q.v.) was here. The manufactures are sugar, woollen cloth, machinery, carpets, and there is a large trade in grain. Moses Mendelssohn was a native. Leopold, Prince of Anhalt-Dessau (1678-1747), a famous soldier in the wars of the 18th century, is popularly known as *der alte Dessauer* ('the old Dessauer'); his statue adorns the market-place. Pop. (1885) 27,584.

Destouches, PHILIPPE, one of the chief comic dramatists of France in the 18th century, was born in 1680. He wrote seventeen comedies, two of which, *Le Philosophe Marié* (1727), and *Le Glorieux*, his masterpiece (1732), are of a very high order of excellence. He died in 1754. His characters are truthfully drawn, and his plots interesting. In his style he imitated Boileau rather than Molière, and his verse has occasionally a happy epigrammatic turn. In his language he avoided the freedom

of the older comedians, but the moral tone of his plays is not high.

Desuetude, a technical term in the law of Scotland, signifying that repeal or revocation of a legal enactment which is effected not by a subsequent enactment in a contrary sense, but by the establishment of a contrary use, sanctioned by the lapse of time and the consent of the community. Neither the word nor the idea attached to it is familiar to the law of England—where the corresponding term is *non-user*. The rule in England is, that a statute once formally enacted by the legislature, remains in force, however unsuited it may be to the altered conditions of society, till it be repealed by another statute. The repeal may be by implication, but here the law watches with a jealous eye. Such repeal 'is to be understood,' says Blackstone, 'only when the matter of the later statute is so clearly repugnant that it necessarily implies a negative.' So far was this principle carried, that it was formerly the rule, that if a statute repealing another was itself repealed afterwards, the first statute was revived without any formal words for that purpose. But this rule was changed by 13 and 14 Viet. chap. 21. In Scotland, an opposite principle prevailed, and it is still held that acts of parliament made before the Union may lose their force by disuse, without any express repeal, or 'go into desuetude,' as it is commonly said. The same may be said of the general orders (Acts of Sederunt, as they are called) of the Court of Session. But by desuetude is meant something more than mere non-use for a period of time, however great. There must be contrary use of a positive kind, inconsistent with the statute, and of such a kind as to prove the altered sense of the community; there must, in short, be consuetudinary law in a negative sense; and the so-called desuetude thus amounts to a repeal of statute law by consuetudinary law.

Both rules are liable to objections. The result of that followed in England has been that statutes have remained on the statute-book without formal repeal after their enforcement had become morally impossible. A curious example of this occurred in the early part of this century, in which one of the parties to an ordinary civil suit challenged his adversary to 'judicial combat,' founding his claim to do so upon an unrepealed statute, and it was held that in point of form his right could not be disputed (see DUEL). But since 1869 the English statutes have been by the Statute Law Revision Acts weeded to a great extent of all obsolete and inconsistent enactments, and a new edition of Revised Statutes has been published, containing as far as possible only such enactments as are in force. The rule in Scotland is the same as the English as regards all statutes made since the Union; but as regards the older Scotch statutes, the difficulty still exists, in dealing with enactments more or less forgotten or violated, how to determine what constitutes such contrary use as to support the plea of desuetude. The effect of the plea of desuetude has been curiously illustrated in some modern cases, where the validity of certain old Scots acts against Sabbath profanation was questioned. In two cases, in 1870 and again in 1887 (when a person was charged with keeping open a pie and lemonade shop in contravention of the Act of 1661), the plea of desuetude was disregarded.

Detachment, in its Military sense, is a small but indefinite number of troops, sent from the main body of a regiment, brigade, division, or army, as the case may be, to perform some special duty. In the Royal Artillery the party of men who work one gun is called a 'gun detachment.' In a fleet

a detachment of one or more ships may be told off in a similar way.

Detective. See POLICE.

Determinants, the name given to a new method of great use, *inter alia*, in the solution of equations embracing several unknown quantities, whereby the student can almost on inspection write down the values, in terms of the known quantities, of each of the unknown.

Determinism, the doctrine that the will is not free, but determined. See WILL.

Detinue, in Law, an action for the recovery of goods wrongfully detained, or their value, with damages and costs.

Detmold, capital of the German principality of Lippe, on the Werre, 47 miles SW. of Hanover by rail. The chief buildings are the old castle, the modern palace, and the theatre. Detmold has also a museum, a public library, a hospital, a gymnasium, and several other schools. There are manufactures of tobacco, cards, and carved work in wood and stone, as well as several breweries. On a hill 2 miles from Detmold is a colossal statue of Arminius (q.v.). Pop. (1885) 8916.

Detonation is the phenomenon of combustion with explosive rapidity, accompanied by sound and light. Thus the firing of gunpowder, gun-cotton, and fulminating-powders, as in a percussion-cap, is detonation.

Detritus, applied in Geology to accumulations formed by the disintegration of rocks, may consist of angular and subangular debris, or of more or less water-worn materials, such as gravel, sand, or clay, or an admixture of these.

Detroit, the chief commercial city and port of entry of Michigan, and seat of justice of Wayne county, is situated on a river of Copyright 1899 in U.S. by J. B. Lippincott & Co. Company. its own name, about 125 miles by water, or 178 by land, NW. of Cleveland, Ohio, with which it is connected by daily steamers and by railway lines. Railways also connect Detroit with Chicago, 284 miles distant, and direct lines extend to all the principal places in Michigan. By way of Windsor on the opposite side of the river, the Grand Trunk Railway of Canada affords direct communication with the cities of the Dominion, and a large number of vessels ply between this city and the other ports on the Great Lakes.

Detroit is substantially built upon rising ground, its streets are broad, well paved, and shaded with trees. It is well supplied with the best of water, pumped from the river by massive engines. Its fire and notice departments are excellent, and its system of public schools, embracing buildings and appliances valued at over \$1,000,000, afford accommodation for about 25,000 pupils. The principal manufactures of the city include iron products, machinery, railroad cars, flour, malt liquors, cigars, leather, boots and shoes, &c., and the mercantile transactions embrace a large trade in grain (of which about 12,000,000 bushels are received annually), flour, live-stock, lumber, wool, &c. Detroit has eight national banks, with a capital of \$4,000,000, and twelve savings-banks, with a capital of \$2,120,000. The aggregate clearings of the associated banks for 1887 were \$198,085,925. The values of the imports and exports for the same year were respectively \$2,833,661 and \$4,344,020. Its public buildings embrace a Catholic cathedral and numerous churches of almost all denominations, a city-hall erected at a cost of about \$600,000, a new Board of Trade building, a convent, a United States marine hospital, &c. Six daily newspapers and numerous weekly and monthly periodicals are published here, of which

several are in the Teutonic language. Detroit is among the oldest places in the United States. It came into possession of the French in 1610, was transferred to the British in 1763, and in 1796 passed to the United States. It was incorporated as a city in 1824. Pop. (1870) 79,577; (1880) 116,340; (1888) estimated 160,000.

Detroit River, so called, upon the north-western bank of which stands the city of the same name, is the strait through which the waters of Lake St Clair, and of the great upper lakes of the St Lawrence system, flow into Lake Erie, and thence to the Atlantic Ocean. It is about 20 miles in length, with a depth sufficient to float the largest vessels, and at Detroit forms an excellent harbour for shipping.

Dettingen, a village of Bavaria, on the Main, 10 miles NW. of Aschaffenburg by rail (pop. 637), is noted as the scene of a battle during the war of the Austrian Succession, when, on 27th June 1743, George II. (q.v.) of England, commanding English, Hanoverians, and Austrians, defeated the larger French army under the Duc de Noailles. This was the last time a king of England took the field in person.—There is another Dettingen (pop. 3500) 10 miles E. of Reutlingen in Württemberg.

Deucalion, son of Prometheus, and husband of Pyrrha. When Zeus had resolved to destroy the race of men by a flood, after the treatment he had received from Lycaon, Deucalion built an ark or ship, in which he and his wife floated during the nine days' flood which drowned all the other inhabitants of Hellas. On the subsidence of the waters the ark rested on Mount Parnassus. To repopulate the world Deucalion and Pyrrha were told by the goddess Themis to throw behind them the bones of their mother. This they did with the stones of mother-earth, and from those thrown by Deucalion sprang up men, and from those by Pyrrha, women.

Deuteronomy (Gr. *deuteronomion*, the 'second' or 'repeated law'), the Greek name of the fifth book of the Pentateuch. It presents the third and latest phase of the development of the Mosaic legislation. Its great aim is to check the encroachments of idolatry, and to concentrate the national worship in the great sanctuary at Jerusalem, especially at the three annual festivals. It is instinct with the prophetic spirit, and lays stress on the great commandment to love and fear God with the whole heart as the sum of the whole law. According to Kuenen and Wellhausen it was composed in the reign of Josiah; other critics think it cannot be later than the reign of Manasseh. See BIBLE, PENTATEUCH.

Deutsch, EMANUEL OSCAR MENAHEM, was born of Jewish parents at Neisse, in Silesia, October 23, 1829. His education was begun at the local gymnasium at the age of six, continued by his uncle, a learned rabbi, to whom he owed his mastery of Hebrew and Chaldean literature, and finally pursued at the university of Berlin. In 1855 he came to England to fill an appointment in the library of the British Museum, where 'for fifteen years with mighty ardour and magnificent industry he studied and wrote, enjoying life among his friends, yet more among his books; shedding sunshine wherever he went, attracting and attaching not a few.' He is best known to the outside world by his brilliant article on the *Talmud* in the *Quarterly Review* (1867), to which he also contributed an article on *Islam* (1869). He wrote excellent articles on the *Targum* and the *Samaritan Pentateuch* for Dr Smith's *Dictionary of the Bible*, and was a valued contributor to the first edition of *Chambers's Encyclopædia*, for which he wrote nearly two hundred articles. His scholarship was seen

to great advantage when he wrote on Phœnician antiquities; and his remarkable command of a vigorous and poetic English style was shown in his articles in the *Times* on the Ecumenical Council. He died 12th May 1873 at Alexandria, whither he had gone in the hope of recovering the health which overwork had undermined. The dream of his life was to have written an elaborate work on the *Talmud*, of which his short essays and lectures gave brilliant promise; but a mortal disease, added to official duties, deprived the world of the results of his unrivalled learning. A volume of his *Literary Remains*, with a sketch of his life by Lady Strangford, was published in 1874.

Deutschbrod, a town of 5436 inhabitants, in the south-east of Bohemia, 15 miles from the Moravian frontier. Here in 1422 the Hussite general Ziska defeated the Emperor Sigismund.

Deutz. See COLOGNE.

Deutzia, a genus of Saxifragaceæ (sub-order Philadelphaceæ), natives of the north of India, China, and Japan. Some are favourite greenhouse plants in Britain, producing abundance of beautiful white flowers. The commonest species (*D. scabra*) is also becoming frequent in shrub-beries.

Deux-ponts. See ZWEIBRÜCKEN.

Deux-Sèvres. See SÈVRES.

Devanāgarī (lit. 'town-script of the gods'), the character most widely understood by Hindu scholars, in which Sanskrit works are usually printed, unless when in Roman letters. See SANSKRIT, ALPHABET.

Devaprayaga (better *Deoprayag*), a village in the district of Garhwal, North-west Provinces of India, on a mountain side, 2266 feet above the sea, in the fork of the Alaknanda and the Bhagirathi, which join to form the Ganges (q.v.). Devaprayaga possesses a notable temple, and is a favourite place of pilgrimage for the Hindus.

Development. See EMBRYOLOGY.

Development Theory. See DARWINIAN THEORY, EVOLUTION.

Dev'enter, an old Hanse town of Holland, in the province of Overijssel, on the Yssel, 11 miles NNW. of Zutphen by rail. It has a cathedral and other interesting churches, a fine town-house, an iron-foundry, and factories for carpet-weaving and the preparation of gingerbread. Thomas à Kempis died here, and in the Latin school Erasmus was educated. Pop. (1888) 22,700.

De Vere, AUBREY THOMAS, poet, was born 10th January 1814, third son of Sir Aubrey De Vere, the second baronet, of Curragh Chase, County Limerick. He had his education at Trinity College, Dublin, and first appeared as a poet in 1842 with *The Waldenses, or the Fall of Kova; a Lyrical Tale*. Next year his *Searches after Prosperine* made him widely and favourably known as a writer of verse, graceful, refined, and fluent, if somewhat feeble and lacking in genuine inspiration. Later volumes are *Poems, Miscellaneous and Sacred* (1853); *May Carols* (1857); *The Sisters; Innisfail* (1861); *Irish Odes and other Poems* (1869); *The Legends of St Patrick* (1872); *Legends of the Saxon Saints* (1879); and *The Foray of Queen Meave, and other Legends of Ireland's Heroic Age* (1882). Mr De Vere has also published poetical dramas on Alexander the Great (1874), and St Thomas of Canterbury (1876), *Essays, chiefly on Poetry* (2 vols. 1887), and other works on Irish ecclesiastical politics and literary criticism.

Deveron, a beautiful salmon river of Aberdeen and Banff shires, rising 3 miles SW. of the Buck of Cabrach, at an altitude of 1847 feet, and thence

winding 62 miles north-eastward, till it falls into the Moray Firth at Banff. See *Lauder's Moray Floods* (1830).

Deviation. See COMPASS.

Device (late Lat. *divisa*, 'a drawing'), if in a wider sense, applicable to emblems on shields, such as described by Homer, is, in a more restricted use of the word, a decoration with accompanying legend, assumed by an individual rather than a family, and for the purpose not of publicity, like the badge (with which it has sometimes been confounded), but of mystification, with covert allusion to the circumstances of the bearer. It is, in fact, a rebus or painted riddle, with a legend allusive to it, as the knot borne by Sir Thomas Heneage, of a shape suggestive of a heart, with the inscription 'Fast though untied'; and the heart borne by Lord Latimer, with the legend 'Dieu et ma fiancée.' See BADGE.

Devil, or Satan, the names applied in the New Testament and in Christian theology to the supreme impersonation of evil, considered as possessing an objective existence outside of man, and placed at the head of a host of inferior evil spirits, whose continual occupation is to thwart the good purposes of God and the progress of his kingdom in the hearts of men. Other names merely suggest the same essential ideas of his nature and function, as *the wicked one*, *the enemy*, and the like. It seems certain that this conception was foreign to the early Jewish mind, with its strong grasp of the monotheistic idea in the person of the supreme Jehovah. It is Jehovah himself who hardens Pharaoh's heart, and sends a lying spirit among the prophets of Ahab, and it is he who is considered as the sole source of all power, the sender of pestilence and death as well as blessings. In the exegesis of later days the serpent that tempted Eve in Eden, and the 'Old Serpent' of the Apocalypse, were alike identified with Satan, although this interpretation certainly gains no support from the story in Genesis, where the tempter is as yet hardly more than a mere animal, although one of a family almost everywhere specially associated with evil.

It is significant that the name Satan occurs but five times in the Old Testament: thrice in Job, where he presents himself among the 'sons of God' (*Beni Elohim*) before the Lord. Here he is the willing messenger of evil, but yet he is not represented as Job's spiritual enemy, nor yet as a distinct impersonation of evil. He is hardly more than an agent of one form of divine providence, by whose means Job is tried and lifted into a higher spiritual plane, and his energies hardly range out of the region of mere physical into that of moral evil. The *Beni Elohim* throughout are employed as the messengers of Jehovah, and carry out his mercies and punishments alike, both bearing messages of consolation and promise to the patriarchs, and filling Saul's mind with gloomy thoughts, appearing with drawn sword to Balaam, or destroying in one night a whole Assyrian host. The Jews had also their demonology like all primitive peoples, as may be seen in the *scirim* (satyrs, lit. 'he-goats') and the *shedim*, both rendered by 'devils' in the authorised version, and perhaps also in the Azazel of Leviticus xvi.; but it was not till later that a special angel became differentiated from his brethren in the heavenly court, with the special function of the accuser of men, like the personification of a guilty conscience. In the vision of Zechariah we find him considered formally as the accuser of Israel. Undoubtedly also this conception had already become greatly modified during the period of exile by contact with Persian dualism. Of course such a conception as Ahriman, the mighty author of evil and the antagonist almost on equal terms of

Ormuzd, was completely foreign to Jewish monotheism, yet the Jewish Satan grew greatly both in definiteness and in power under his shadow, and henceforth it is from him directly that moral and physical harm towards men proceeds. Yet it must not be supposed that this was due to direct borrowing, and that the Jewish Satan was not substantially an original evolution of the native Jewish mind. 'While Ahriman is physical evil that has become moral evil also,' says M. Réville, 'Satan is moral evil becoming physical evil.'

Persian influence appears most plainly in the apocryphal books of Tobit and Baruch, but the growth of the conception of the devil is seen also in the translation of the LXX., which renders his name by *diabolos*, thus emphasising and perpetuating his special function as the *accuser*. Now also he becomes located in his gloomy kingdom of hell, and is attended by troops of inferior fiends. He wages warfare on mankind by inflicting physical and moral evil, and is considered as the agent by whose means man fell from his original state of innocence. It was thus he who introduced death with all its horrors into the world, and consequently diseases, especially those of greater violence and obscurity, are the work of himself or his minions.

In the New Testament the conception of the personality of the devil and of a kingdom of demons holds its ground, but the whole subject is here treated with a kind of spiritual reserve, in a teaching that emphasises our own hearts and their inward temptations as the source of our evil thoughts and deeds, and connects moral evil inseparably with the earthly nature of man. The passages which speak of a fall of angelic beings (2 Peter, ii. 4; Jude 6) occur in scriptures of subordinate canonical rank; Jesus nowhere defines concretely the function of the devil; and the few positive statements about him—that 'he was a murderer from the beginning, and stood not in the truth,' that 'he is a liar' (John, viii. 44), and 'sineth from the beginning' (1 John, iii. 8), scarcely furnish a sufficient foundation for a complete doctrine on this subject. Yet the impressive manner in which it is dwelt on by our Lord and his apostles shows that it is a necessary part of Christian teaching. The New Testament devil is an enemy of the divine, but yet an inferior and degraded spirit. He is the tempter of man, and even of the Son of God, yet his temptations fall without effect upon upright purity, and through the Saviour's merits the individual Christian is also saved from his power, in spite of all the perilous temptations of his own flesh. Christ's saving work is regarded as the virtual victory over the power of Satan, and the grand drama of the last decisive struggles and final subjugation of the kingdom of the devil forms the conclusion of New Testament prophecy.

The early theologians were more literal and less spiritual in their conceptions, and in their horror of heathen institutions came to identify the kingdom of the devil in a particular manner with polytheism and the persecution they suffered under the Roman empire. Thus the devil again became a kind of rival of God, wholly unequal but yet formidable. The strength of the belief in a powerful personal devil may be seen in the earliest heresies, those of the Gnostics and Manichæans, a main feature in which was an elaborate system of evil demons as enemies to man and almost rivals to God. The early Christians considered the gods of heathenism as indeed conquered by Christ, but yet not rendered wholly powerless, for as degraded demons and with intent to deceive they uttered oracles, and were present at sacrifices, inhaling the sacrificial incense—an idea in perfect harmony with the growing materialistic conception of the devils,

and of hell their residence, a place blazing with eternal fire, and filled with every horror the imagination could suggest. The belief in the objective personality of Satan was complete in the literalistic explanation of the 'descent into hell,' and the release of the 'spirits in prison.' It was a literal conquest over an enemy, although by some it was explained almost as if due to superior cunning rather than superior power.

Exaggerated ideas of the devil's dangerous power prevailed throughout the dark and middle ages, whose deep melancholy faith and fantastic theory of the universe generated saints naturally on the one hand, and witches and sorcerers as naturally on the other. It was an involuntary exercise of the poetic faculty, through which the thoughts of their own hearts and of their own time became spirits, which they saw around them. Countless legends were originated of actual contests between individual saints and devils in one or other of a thousand forms. Safety from the devil could be found alone within the charmed ring-fence of the church, fortified by the ordained sacraments and by personal cleanness of life. Excommunication was synonymous with being 'delivered over to Satan,' to whom the popular imagination transferred freely all the lingering remnants of earlier demonologies, so that that particular form and those particular attributes became permanently associated with his appearance which medieval art has fixed and handed down to us. Lechery had ever been a persistent quality of the devil (from the literal interpretation of Gen. vi. 2), and the popular imagination working out this idea gave free play to a fearful but prurient fancy, which revelled in multiplying all the disgusting details of a witches' sabbath. Throughout the middle ages the devil was an absorbing idea, and the constant familiarity with him often brought with it a penalty of contempt. In the old religious plays a principal part was usually assigned to him, and indeed he principally represented the comic element, as may still be seen in the *pastorales* of the Basques. The auditors might laugh for the moment to see the devil outwitted and then beaten, but they had not shaken off that fear which revenged itself in all the pitiless cruelties of witchcraft—the darkest chapter in the history of humanity.

The decadence of belief in the active external power of the devil was mainly due to the indirect effect of the Reformation and the progress of science. To no man was the devil ever more present than to Luther, but nevertheless it was mainly the movement he inaugurated that has driven the enemy back into the sphere of the abstract and the ideal. In later generations the sense of the supernatural has steadily decayed, and with it almost all the terrors of the devil; but it cannot be said that with it has also disappeared a genuine religious spirit. The Christian man in the conscious weakness of his struggle against indwelling sin feels that he has no need to conjure up for himself an external suggester of temptation—he has devils enough in the treacherous inclinations of his own heart. And in assuming a personal devil to account for the evil side that there is in nature and in life, there remains the question to be answered whether we have not merely pushed back the most puzzling of all questions a single stage, and whether we have contributed at all to the insoluble problem of the genesis of evil.

Kant (in 1793) defined the devil as the personification of 'radical evil.' Schleiermacher held that symbolic reference to the devil might fitly have a place in Christian discourse, but denied the possibility of his real existence, and in this he has been followed by Schenkel, Biedermann, Lipsius,

Pfeiderer, and others. Pfeiderer, estimating the critical result of the doctrine, finds that—whilst a twofold logical contradiction is involved in the idea of devils as the substantial existence of wickedness, and as supra-mundane creatures belonging to this world—devils represent the obverse of religious idealism, or empirical world-existence in its hostility to the Idea: in other words, the world on the side of its opposition to God, or the working for itself of finite and opposing existence as such, presenting itself as the sum and substance of evil. That the two forms of evil—the natural and the spiritual or moral—stand in inward connection, and form a universal (and accordingly metaphysical) power in the world, is the truth contained in the idea of the devil that has significance for the practice of worship. On the other hand the orthodox view is maintained more or less definitely by Lücke, Von Hofmann, Luthardt, Rothe, Julius Müller, Martensen, and Dorner, who holds that though the doctrine cannot be completely constructed, it yet forms part of a consistent whole, and is of importance for the Christian, as distinguished from the heathen and Jewish conception of evil, as well as for the Christian life. See ATONEMENT, DEMON- OLOGY, EVIL, EXORCISM, HELL, WITCHCRAFT; also Roskoff's admirable *Geschichte des Teufels* (1869).

Devil-fish is a name used for the Octopus (q.v.), also for the Angler (q.v.), and, in America, for a gigantic species of ray (*Cephalopterus vampyrus*), with very large pectorals. Of the latter a specimen was found in Delaware Bay, 17½ feet by 18 feet, and weighing 5 tons.

Devil's Bit. See SCABIOUS.

Devil's Bridge, a popular name in most mountainous countries for bridges built over wild chasms. The most notable are (1) a bridge over the Reuss, in the Swiss canton of Uri, 1½ mile W. of Andermatt, on the St Gothard Road, where the river, 4503 feet above sea-level, forms a picturesque cascade of 100 feet. The new granite structure, built in 1830, spanning the stream with a single arch of 26 feet, fell in in August 1888, and traffic was for a time resumed on the old moss-grown bridge 20 feet below, which witnessed some severe fighting between the French and the Austrians and Russians in 1799. (2) A double bridge in Cardiganshire (sometimes called *Pont-y-Mynach*), 10 miles ESE. of Aberystwith, across a gorge, 114 feet deep, and over a mile long, traversed by the Mynach, which makes within a short distance four falls of from 18 to 110 feet. The lower bridge was constructed by the monks of Strata Florida in the 11th century, the upper (20 feet over it) in 1753.

Devil's Coach-horse (*Ocyptus olens*), a common British and European beetle, in the family Staphylinidæ. It has very much reduced wing-covers, and resembles many of its relatives in the habit of curving its posterior body upwards, using the tip to adjust the wings under their covers.

Devil's Dyke. See CAMBRIDGESHIRE.

Devise, the conveyance of land by Will (q.v.).

Devizes, a municipal borough of Wiltshire, near the Kennet and Avon Canal, 50 miles WSW. of Reading, and 20 ESE. of Bath. It lies high at the mouth of Pewsey Vale, between the thinly peopled tracts of Salisbury Plain and the Marlborough Downs. According to Dr Guest, the old name *Divisæ* or *Ad Divisas* marked the ancient boundary between the English and Celts; anyhow, as a town, Devizes owes its origin to a splendid castle built here by Bishop Roger of Salisbury about 1132. It was stormed by Cromwell in 1645, and now is represented by mere fragments. There are two churches with much interesting Norman work; a market-cross (1814), commemorating God's

judgment on a perjurer in 1753; a fountain with a statue of Sothern Estcourt (1879); a good museum; and a large corn exchange (1857). It has manufactures of snuff and malt, and is the seat of an important corn-market. From Henry VIII.'s time till about 1820 Devizes was a great cloth mart; now its chief manufactures are snuff and agricultural implements. It returned two members till 1867, then one till 1885. Pop. (1851) 6554; (1881) 6645. See *A History of Devizes* (1859).

Devonian System. The name proposed by Murchison and Sedgwick to replace the more characteristic and older term Old Red Sandstone, because the slaty and calciferous strata in Devonshire contain a much more copious and rich fossil fauna than the red arenaceous rocks of Scotland, Wales, and Herefordshire, with which they are believed to be upon the whole contemporaneous. The physical condition under which the strata in Devonshire were deposited differed greatly from those which marked the accumulation of the Old Red Sandstone, and there is still some doubt as to the precise correlation of the two sets of strata. Geologists, therefore, retain both names, and speak of the *Devonian and Old Red Sandstone* system, or *Old Red Sandstone and Devonian* system. See OLD RED SANDSTONE.

Devonport (before 1824 called PLYMOUTH DOCK), a parliamentary and municipal borough, maritime town, and naval arsenal, in the south-west of Devonshire, on the east shore of the estuary of the Tamar (which is 4 miles long by $\frac{1}{2}$ mile broad, and called the Hamoaze), 2 miles WNW. of Plymouth. It stands on high ground, and is separated from its growing suburbs of Stoke and Morice Town by the glacis of its fortifications, once important, but now dismantled. The streets are regular, and the footpaths of marble. Devonport is supplied with water from Dartmoor by a circuitous route of 30 miles. It owes its existence to the dockyard established here by William III. in 1689, and is one of the chief naval arsenals in Britain. The government establishments now stretch for nearly 4 miles along the left bank of the Hamoaze. The original dockyard, extended from time to time until it contained six building-slips, was supplemented in 1844 by the formation at Morice Town of the Keyham Steam Yard and Factory, which communicates with the dockyard and gun-wharf (designed by Vanbrugh) by a tunnel. Farther up the river are an engineers' college, seamen's barracks, magazines, and powder-works; and the Hamoaze itself contains many men-of-war lying in ordinary, besides those in actual service. The official residences of the admiral of the port and of the lieutenant-governor of the western district are at Mount Wise, which is fortified. Here also are the chief barracks of the troops which garrison the 'three towns' of Plymouth, Devonport, and Stonehouse. The military hospital is on Stonehouse Creek. There are extensive commercial wharves with railway communication on Stonehouse Pool. Pop. of municipal borough (1841) 33,820; (1881) 48,939; of parliamentary borough, which includes the adjacent township of East Stonehouse, 63,870. Devonport returns two members to parliament.

Devonshire, a maritime county, in the south-west peninsula of England, between the Bristol and the English Channel. Its greatest length is 70 miles; its greatest breadth, 65; and it contains 2536 sq. m., of which about three-fourths are under cultivation. The coast-line approaches 150 miles. The north coast is the boldest, with several hills over 1000 feet. Its chief indentation is Bideford Bay, 18 miles broad and 8 deep, into which fall the Taw and the Torridge. The south coast is also

lined with cliffs, chief among them being the bold promontorial district of the Bolt Head and Start Point, the western horn of the great bay of which Portland is the eastern. Tor Bay is 3 by $3\frac{1}{2}$ miles. Plymouth Sound, the combined estuary of the Tamar and Plym, is one of the finest harbours in the kingdom, the anchorage ground extending 7 miles inland from the breakwater (see PLYMOUTH) by which the outer roadstead is protected. Devonshire is hilly, the most elevated parts being the tablelands of Dartmoor in the south-west, Exmoor in the north-west, running into Somerset, and Blackdown in the east. These are mainly open moorlands. Dartmoor (q.v.) is very rocky; the lower hills grassy. High Willhayse, on Dartmoor (2039 feet), is the highest point. Devonian and Carboniferous strata occupy the greater part of the county; next in importance are the granitic boss of Dartmoor, and the Triassic rocks in the eastern quarter. There are also archæan rocks, probably Silurian, with greensand, chalk, a Miocene deposit at Bovey Tracey, and many exposures of igneous rocks, intrusive and interbedded. Copper, tin, lead, iron, and manganese occur in commercial quantities, with ores of several other metals; china, terracotta, potter's, and pipe clays; granites, marbles, anthracite, lignite, gypsum, and other earthly minerals. The rivers of Devonshire are numerous. The Tamar, 59 miles, is the longest, and divides Devon from Cornwall; the Exe, 54 miles, which comes next, rises in Somerset. The other leading rivers rise in Dartmoor—the Dart, Teign, Taw, Torridge, and Plym have all estuaries of commercial importance, with the Exe and Tamar. The red deer still run wild on Exmoor, and are hunted.

The climate of Devon, especially in the south, is mild and humid, and not liable to great extremes. Hence, several of the towns on the southern and eastern coasts have become famous as health-resorts—notably Torquay; and, on the north coast, Ilfracombe. Myrtles and aloes commonly flourish in the open air; and in specially favoured spots oranges and lemons, with a little protection, will thrive and fruit. The rainfall on Dartmoor is much greater than elsewhere in Devon, and the winters colder and more bracing. The climate is so invigorating, however, that the Moor is rapidly growing into repute as a summer sanatorium, and that the convict prison is regarded as a health-station. The county is most fertile, especially in the South Hams, and on the 'red land' of the Vale of Exeter. The pastures are very rich, and dairy-farming and cattle-breeding are prominent in its agriculture. The red Devon cattle are one of the leading breeds; and the sheep and ponies of Dartmoor and Exmoor have more than a local reputation. 'Clotted cream,' produced by scalding, is a special product almost confined to Devon and Cornwall. There are extensive orchards, from which great quantities of cider are made; and various fruits are largely cultivated in special localities and sent to London and the Midlands by rail. The fisheries are extensive and valuable, the chief centres being Plymouth and Brixham. Though in the main agricultural, Devon has a varied industrial character. Mining and quarrying and clay-working are of considerable importance; and the manufactures include serges, lace, gloves; extensive potteries; manure, chemical, and soap works; paper-mills, breweries, and distilleries. The chief towns are the city of Exeter, Plymouth, Devonport, Torquay, Tiverton, Barnstaple, Stonehouse, Tavistock, Teignmouth, Newton, Dartmouth, and Brixham. Pop. (1801) 340,308; (1841) 532,959; (1881) 604,397. Under the Reform Act of 1885 Exeter returns one member, Plymouth and Devonport two each, and the rest of the county is divided into eight single-member constituencies.

Devon adds to singular landscape charms, anti-quarian attractions of a most comprehensive and varied character, prehistoric and medieval. The Romans had little to do with it beyond Exeter, which was an important station; the Saxons did not conquer it until the reign of Cynewulf; the Danes ravaged it in the 9th and 10th centuries, though they were at first repulsed with heavy loss; it was the scene of the western rebellion for the restoration of Roman Catholicism in 1549; Plymouth was the headquarters of the fleet which defeated the Armada in 1588, and the chief mainstay of the parliament in the west of England in the conflict with Charles I.; Brixham was the landing-place in 1688 of William of Orange. No county save Middlesex has given birth to so many eminent men—Raleigh, Drake, Hawkins, Marlborough, Monk, Coleridge, Hooker, Sir Joshua Reynolds, John Davis, Sir Humphrey Gilbert, Sir Richard Grenville, Bishop Jewell, Gay, St Boniface, New-comin, Wolcott, Kingsley, John Ford, among them.

Devonshire, DUKE OF. See CAVENDISH.

Devrient, a family of German actors, of whom the most talented was Ludwig Devrient (1784-1832), distinguished both in comedy and in tragedy, and especially noteworthy as an exponent of Shakespearean characters.—His nephew, Carl August (1797-1872), the eldest of the brothers Devrient, played lovers' parts, and was the husband of the *diva*, Madame Schröder-Devrient (1805-60).—Philipp Eduard (1801-77), the second brother, was a delightful baritone singer in the early part of the century, and afterwards became a painstaking, though not a great actor. He was the author of a number of plays, and of the valuable *Geschichte der deutschen Schauspielkunst* (Leip. 5 vols. 1848-74); and with his son Otto (born 1838) he prepared an edition of Shakespeare.—Gustav Emil (1803-72), the youngest and most gifted of the three brothers, was most successful in tragic and emotional parts, and became identified in Germany with such characters as Hamlet, Tasso, and especially Posa.

Dew. The question of the origin of dew has been discussed since very early times, and many theories have been advanced on the subject. Among more recent writers, Gersten, followed by Du Fay, held that dew rose from the ground. Others believed that it fell from above, but no really systematic treatment of the subject appeared until the publication of Wells's *Essay on Dew* in 1814. Wells combated the opinion of Du Fay and Gersten, and showed that all the phenomena described by them could be equally well explained by his theory. He asserted that the dew was condensed out of the air in contact with surfaces below a certain temperature. For every definite pressure and temperature of the atmosphere there is a definite amount of water-vapour per unit-volume which can be held in suspension. Hence, when air containing a certain amount of water-vapour is cooled below a particular temperature, the vapour is condensed. This temperature is called the *dew-point* of the atmosphere under the given conditions as to pressure and quantity of vapour. At night the earth and objects at its surface are being cooled by radiation. If the rate of loss of heat by radiation is sufficiently rapid, the temperature of the earth's surface, and consequently of the air in immediate contact with it, may fall below the dew-point. When this occurs, the moisture condenses on the surface in the form of dew. This is Dr Wells's theory regarding the formation of dew. He considered that the vapour had risen from the ground during the previous day, and that very little dew was formed from vapour which had just risen from the ground, although he admitted that some might be so produced.

Wells's theory of the formation of dew is undoubtedly correct, but, in a paper read in 1885 before the Royal Society of Edinburgh, Mr John Aitken has adduced evidence which shows that the greater part of dew is formed from vapour which has just risen from the ground and been trapped by the grass and other objects. Mr Aitken was led to this conclusion by three independent experimental methods. One of these consists in removing at sunset a portion of turf from the ground, placing it in a shallow metal pan and weighing it. The turf, still contained in the pan, is then replaced in the ground in good heat-communication with it. When reweighed after some time, it is invariably found to have lost weight. If the turf be covered by a metal tray so as to prevent escape of moisture, this loss of weight is largely obviated. Similarly, it is shown that moisture rises always during the night from bare soil, from roads, and from the driest earth.

Certain atmospheric conditions are necessary for the copious formation of dew. The sky must be clear, otherwise the clouds will radiate back much of the heat given off from the earth, and so will prevent the surface objects from cooling below the dew-point. The atmosphere must be calm, or the air in immediate contact with the ground will be carried away before it is completely saturated.

When the temperature of objects falls below the freezing-point, the dew is deposited in a solid state, and is known as *hoar-frost*. See EVAPORATION, METEOROLOGY.

Dewas', a native state of Central India, under British protection, held conjointly by two Rajput chiefs. Area under both chiefs, 289 sq. m.; pop. (1881) 142,162. The capital, Dewas, 20 miles N.E. of Indore, is a straggling town, with a pop. of 11,921.

Dewberry (*Rubus cæsius*) is distinguished from the Common Bramble (of which, indeed, many regard it as a mere sub-species) by its weaker and more prostrate glaucous stem, with scattered prickles, but without bristles or glandular hairs, also by the few large drupes, which make up its fruit, and which have a characteristic dew-like bloom, whence the name arises. The fruit is very sweet and agreeable, and makes an excellent wine. The dewberry of North America (*R. procumbens*), abundant in the forests of Canada, is a delicious fruit, much superior to the British fruit of the same name, and more tart. The plant is of very humble growth, scarcely rising above the ground.

D'Ewes, SIR SIMONDS, antiquary, was born in 1602 at Coxden, near Chard, of Suffolk and Dorset parentage, and was educated under four masters in those two counties and in London, till in 1618 he entered St John's College, Cambridge. In 1623 he was called to the bar, but three years afterwards threw up his practice, married the rich child-heiress Anne Clopton (1613-41), and received the honour of knighthood. He now devoted himself to his darling pursuits, numismatics and historical manuscripts, whence in 1640 he was called away to the Long Parliament as member for Sudbury. A Puritan but a moderate, he accepted a baronetcy (1641), sided with the parliament on the outbreak of the Civil War, was expelled by Pride (1648), and, withdrawing to Suffolk, died at Stow Langtoft Hall, 8th April 1650. He published little, but his transcripts of manuscripts, which else had perished, possess high value, as also do his *Diaries*, especially the portions relating to the Long Parliament, which have been utilised by Mr Forster. His monumental *Journals of Queen Elizabeth's Parliaments* appeared in 1682; and his *Correspondence*, with an incomplete *Autobiography*, was edited in 1845 by Mr Halliwell (Halliwell-Phillipps).

De Wette, WILHELM MARTIN LEBERECHE, biblical critic, was born at Ulla, near Weimar, on the 12th January 1780. He studied from 1799 at Jena, under Griesbach and Paulus, and early attached himself to the philosophy of Fries. He became extraordinary professor of Exegesis at Heidelberg in 1807, and ordinary professor in 1809, and in 1810 was called to the newly-founded university of Berlin. For a letter which he had sent on the 31st March 1819 to his friend, the mother of Sand, the assassin of Kotzebue, he was deprived of his professorship; and retiring to his native place, he completed his *Christliche Sittenlehre* (3 vols. 1819-21), his edition of the *Briefe, Sendschreiben und Bedenken Luthers* (5 vols. 1825-28), and the religious novel *Theodor, oder des Zweiflers Weihe* (1822; Eng. trans. 1849). A call to be preacher at Brunswick was vetoed by the Hanoverian government, and in 1822 he was appointed professor of Theology at Basel, where, in 1829, he was honoured with a seat in the Council of Education, and died 16th June 1849. His great reputation as a biblical scholar rests on his *Beiträge zur Einleitung in das Alte Testament* (2 vols. 1806-7), his *Lehrbuch der hebräisch-jüdischen Archäologie* (1814; 4th ed. 1864), and especially his very useful *Lehrbuch der historisch-kritischen Einleitung in die Bibel* (1817 and 1826), of which the Old Testament part had in 1860 reached its 8th (Eng. trans. by Theodore Parker, 1843), and the New Testament in 1860 its 6th edition (Eng. trans. 1858). His translation of the Scriptures, undertaken in conjunction with Augusti (6 vols. 1809-12; 4th ed. 1858); *Commentar über die Psalmen* (1829; 5th ed. 1856); and *Kurzgefasstes Exegetisches Handbuch zum Neuen Testament* (3 vols. 1836-48), have been extensively used by students, and the separate parts of the last-named work, as revised repeatedly by later scholars, have held their ground ever since. 'He possesses soul enough,' says Tholuck, 'to distinguish between the spiritual kernel and its husk in the language of the Bible; interest, besides, in its ideas and doctrines; and, finally, a sound exegetical tact, equally removed from exegetical coxcombry and from arbitrariness and inexactitude.' His works on dogmatic theology, *Ueber die Religion* (1827), and *Das Wesen des Christlichen Glaubens* (1846), are of less importance. See the estimates of De Wette's merits as an exegete and theologian by D. Schenkel (1849), F. Lücke (1850), Hagenbach (1850), Wiegand (1879), and Stähelin (1880).

De Witt, JAN, a celebrated statesman of Holland, born at Dort in 1625, was the son of Jacob de Witt, a vehement opponent of William II., Prince of Orange. Jan inherited his father's hatred of the office of stadtholder, and of the family that filled it. His education was carefully attended to, and he soon exhibited remarkable ability. He was one of the deputies sent by the States of Holland in 1652 to Zealand, for the purpose of dissuading that province from adopting an Orange policy, and there his eloquence secured him universal confidence. In the same year he was made grand pensionary. The Orange party (supported by the populace and the clergy), during the war carried on between England and Holland, was ever striving to increase the power of the young prince (afterwards William III.), who was then a mere infant; the republican, or oligarchic party, composed of the nobles and the wealthier burgesses, at the head of which was De Witt, on the other hand sought to strip the House of Orange of all power, and to abolish entirely the office of stadtholder. During William's minority the advantage was, of course, with De Witt and the republicans. In 1654, on the conclusion of the war with England, a secret article was inserted in the treaty drawn up between De Witt and Cromwell, in virtue of which

the House of Orange was to be deprived of all state-offices. After the restoration of Charles II., De Witt leaned more to the side of France, all the more when hostilities were renewed between England and Holland in 1665. During the two years' war De Witt's influence declined, but his star paled altogether when the designs of Louis XIV. upon the Spanish Netherlands became manifest. The Orange party carried their point in the elevation of William to the family dignity of stadtholder; and on the invasion of the Netherlands by Louis XIV. in 1672, the Prince of Orange was appointed commander of the Dutch forces. The first campaign proved unfortunate, which did not improve the temper of the people towards De Witt, who had previously resigned his office of grand pensionary. His brother, Cornelius, accused of conspiring against the life of the stadtholder, was imprisoned and tortured. De Witt went to see him on his release. When they were coming out of prison, they were attacked by an infuriated crowd, and were both murdered, August 20, 1672. The States-general demanded an investigation, and the punishment of the murderers, but the stadtholder did not take the necessary steps. De Witt was personally a man of upright character. Among his writings are his *Memoirs* (1709) and his *Letters* (6 vols. 1723-25). See the Lives by Simons (1832-36), Knottenbelt (1862), J. Geddes (vol. i. Lond. 1879), and Pontalis (Eng. trans. 2 vols. 1885).

Dewsbury, a manufacturing town and municipal and parliamentary borough in the West Riding of Yorkshire, situated at the base of a hill, on the left bank of the Calder, 32 miles SW. of York, and 8 miles SSW. of Leeds. The Calder navigation connects the town with Liverpool and Hull. Dewsbury has a chamber of commerce formed in 1861, an infirmary erected in 1883 at a cost of £17,000, a new town-hall erected in 1888 at a cost of £30,000, new county courts, and a grammar-school (St Augustine's). Along with Batley (q.v.) it is the centre of the shoddy trade. Blankets, carpets, and yarns are also largely manufactured. There are also foundries, as well as a number of minor industries. Dewsbury obtained a municipal charter in 1872. Pop. of municipal borough (1861) 18,148; (1881) 29,639; (1888) 33,000. The parliamentary borough was formed in 1867, and includes Batley and Soothill. Pop. of parliamentary borough (1881) 69,531. It returns one member to parliament.

Dexter, in Heraldry, that side of a shield or armorial figure or composition which is to the left, not the right, of the spectator. This nomenclature is adopted because it covers the right side of the warrior who carries the shield.

Dextrine (syn. 'British gum,' 'torrefied starch'). When starch is carefully heated to 392° (200° C.), or until vapours arise from it, it becomes soluble in cold and hot water, and loses its gelatinous character; it also has the property, when viewed by polarised light, of turning the plane of polarisation to the right; hence its name. It is often used as a substitute for gum-arabic in the processes of calico-printing, and for stiffening different goods; it is also applied to the back of postage-stamps. Its value as a substitute for gum consists in its being more flexible and less brittle when dry than that substance. Starch may be converted into dextrine by the long-continued action of dilute acids at a high temperature; also by the action of Diastase (q.v.). Dextrine and starch are isomeric, both being composed of $C_6H_{10}O_5$; but dextrine may be distinguished from the latter body by its not being rendered blue by iodine, which gives with it a dingy purple tint.

Dey (Turkish *dai*, 'a maternal uncle'), a name applied to the governor of Algiers before its

conquest by the French. The name was formerly given to elderly people, especially among the Janizaries; hence came to be commonly applied at Algiers to the commanding-officer of that corps, who frequently became afterwards pashia or regent of that province. See BEG.

Dhar, a town of Central India, lying at an elevation of 1908 feet above the sea, 33 miles W. of Mhow. It has over 15,000 inhabitants, and preserves, in two large mosques of red stone and a fort defended by a high rampart and twenty-six towers, traces of bygone magnificence. It is the capital of a protected state of the same name, with an area of 1740 sq. m., and (1881) 194,274 inhabitants.

Dhamsala, a hill-station in the Punjab, 110 miles N.E. of Lahore. Pop. 5322.

Dharwar, a town and district in the southern Mahratta country, in Bombay presidency, separated by the river Tungabhadra from Madras. The town has no manufactures of importance, but a good deal of trade. Pop. (1881) 27,191.—The district has an area of 4535 sq. m., and a pop. (1881) of 882,907, mostly Hindus. The most interesting feature of the country is its suitability for the growth of American cotton, which now occupies a third of the total acreage devoted to cotton. Cotton and silk cloth are manufactured in the district. The prevalent language is Canarese.

Dhole, the wild dog of India. See DOG.

Dholka, a town of India, in Bombay presidency, 22 miles SW. of Ahmadabad, with a reputation for the weaving of women's robes. It is surrounded by a mud wall 4 miles in circuit, and lies amid the ruins of noble palaces and tanks, many dating from the early Hindu period. Pop. (1881) 17,716.

Dholpore, a native state of Rajputana, in Central India, on the northern bank of the Chumbul, with an area of 1200 sq. m., and a pop. (1881) of 249,657, mostly Hindus. Capital, Dholpore, on the Chumbul, 34 miles S. of Agra by rail. A large fifteen days' fair is held here in October, and two religious fairs are held every year at Machkund, a lake 3 miles to the west, with no fewer than 114 temples on its banks.

Dhunchee, or DHANCHI [*Aschynomene* (*Sesbania*) *aculeata*], an annual herbaceous plant cultivated in Bengal on account of its coarse hemp-like fibre. It is steeped and prepared very much like Sunu (q.v.). Other species are of similar use.

Dhwalagiri (*Dinālagiri*), once supposed to be the highest peak of the Himalayas, but now ascertained to be at most only the third in point of altitude, has a height of 26,826 feet above the sea. It is in Nepal, in 29° N. lat., and 82° 30' E. long.

Diabase. See BASALT.

Diabetes (Gr., lit. 'a syphon,' from *diabainō*, 'I go or flow through'), a disorder of the general system, of which the principal symptom is a greatly increased flow of urine. Diabetes is of two distinct kinds: the one, *diabetes insipidus*, is a mere exaggeration of the water-excreting function of the kidneys, accompanied by extreme thirst, and hence called *polydipsia* (Gr., 'excess of thirst') by some authorities; the other is a more complex disorder of the assimilation, consequent on the formation first, and the excretion by the kidneys afterwards, of an enormous excess of animal sugar (see SUGAR), the sugar being found in excess not only in the renal excretion, but in the blood, and in nearly all the secretions which have been examined. The pathology of this disease, called *diabetes mellitus* (Lat. *mel*, 'honey'), is very obscure, notwithstanding the numerous recent physiological researches which tend to throw light on the development of sugar in the animal organ-

ism, especially in the liver, and which must undoubtedly be regarded as bearing on the solution of the problems connected with this disease. Unhappily, the cure of it is still entirely unknown, except in so far as it may be controlled or retarded by good management of the diet, drink, and clothing. The course of the disease, however, is very different at different periods of life. Before middle age it is severe, progressive, and almost invariably fatal. After that period precisely similar symptoms often appear, especially in gouty persons, but are so much less dangerous, and so much more easily controlled, that many authorities are unwilling to place them in the same class as true diabetes. All diabetics are subject to progressive emaciation, and they often become subject to a chronic disease of the lungs, closely resembling true tubercular Consumption (q.v.); it is chiefly in warding off this termination, or some other more quickly fatal, and in mitigating the symptoms of the malady, that the medical art can be of service.

The first fact observed in cases of diabetes is usually the increased flow of urine, when it becomes so great as to amount to a practical inconvenience; and also a considerable increase of the appetite, and an unquenchable thirst, which rarely fail to accompany the disease from the beginning, but often do not attract attention, or at least suggest the idea of anything wrong, till an advanced stage of the disorder. When the patient demands medical assistance he is usually somewhat thin; the pulse is quiet, the skin cool, the heat of the surface, indeed, habitually rather low and easily depressed. There is often a complete absence of perspiration, which gives a peculiar feeling of harshness to the surface, especially of the palms of the hands. With these symptoms the first approaches of pulmonary disease may concur. In the very last stages there is sometimes dropsy of the feet; and the urine may be natural in quantity, or even diminished. For the other characters of diabetic urine, see URINE. Diabetic persons bear excitement and fatigue, either mental or bodily, extremely badly; and imprudence in this respect is not unfrequently followed by sudden or rapid collapse and death. The treatment consists mainly in removing from the diet, as far as consistent with comfort and due nourishment, everything which easily turns to the formation of animal sugar in the system, especially all excess of farinaceous food. The complete suppression of sugar-forming food, however, as recommended long ago by Rollo, has not been found possible in practice in the majority of cases. Bread composed of gluten of wheat without starch, or bran-cakes baked with eggs, or biscuits made of almonds, have been strongly recommended; and in most of the great capitals, as London and Paris, bakers may be found who regularly furnish bread suitable for this unfortunate class of sufferers; indeed, any intelligent baker who will take the trouble may, under medical direction, be got to manufacture such bread when required; or it may be ordered in the form of cakes and biscuits, in quantities at a time, from London houses. It is of importance, however, that it be ascertained that the bread or flour supplied is really suitable; for Dr Pavy, one of the chief authorities on this disease, ascertained that some of the so-called foods for diabetics contain little less starch than ordinary bread. Saccharin (q.v.) has lately been of great service to diabetics, as it supplies the flavour of sugar without its objectionable properties. Medicines proper should be used only under the advice of the physician. There is no specific, and the unguarded use of strong remedies is to be condemned. Of all medicines that have been used, however, opium and morphia have been found most frequently use-

ful in delaying the progress of the disease. Flannel should be worn next the skin, and the languid function of the cutaneous perspiration aided by the warm bath, especially, perhaps, the vapour bath—e.g. that form known as the Russian bath. The Turkish bath, which abstracts a large quantity of water through the skin, is less suitable to such cases.

Diablerets, a remarkable mountain of the Bernese Alps, Switzerland, on the frontiers of Bern and Valais, with a height of 10,651 feet above the sea. The Diablerets, with their four main peaks, are composed of limestone strata, the lower beds of which are so soft and shaly that they are easily disintegrated, and masses from above tumble over into the valley, occasioning the most terrible catastrophes, as in 1714 and 1749.

Dicaustic. See CAUSTICS.

Diachylon. See PLASTER.

Diadem. See CROWN.

Diæresis (Gr., from *diaireō*, 'I divide'), a term used in Grammar to signify the resolution of a diphthong, or of a contracted syllable, into two syllables; as Lat. *auræ* into *aurai*. The name is also given to the mark \cdot placed above a vowel letter to indicate that it is to be independently pronounced, and not in conjunction with a preceding vowel; as in the above example, or in the word *aërial*. See UMLAUT.

Diagnosis (Gr., from *dia*, 'through,' and *gnōsis*, 'knowledge'), in Medicine, the discrimination of diseases. It includes the study of all the vital phenomena of diseases, and also of their appearances after death, in so far as this can aid their discovery during the life of the patient. It is usual to speak of rational or physiological diagnosis, or diagnosis by symptoms—i.e. changes chiefly functional, observed by the patient; and of physical diagnosis, or diagnosis by signs—i.e. objective phenomena appreciable by the senses of the observer. The latter method of diagnosis has been much enlarged in scope and increased in importance by the modern methods in medicine of Auscultation (q.v.) and Percussion (q.v.), and also by the great advances made in physiological chemistry, and by the use of the microscope. Skill in diagnosis is one of the highest gifts of the physician, and nothing distinguishes the man of long experience from the tyro more than this unerring insight into some unseen disease. See STETHOSCOPE, LARYNGOSCOPE, OPHTHALMOSCOPE, &c.

Diagonal Scale. See SCALES (MATHEMATICAL).

Diagoras (surnamed the 'atheist'), a Greek poet and philosopher, was born in Melos, an island of the Cyclades. He is said to have been a disciple of Democritus of Abdera, and he is alluded to by Aristophanes in the *Clouds* (424 B.C.). He seems to have been witty and fearless, and probably treated the superstitions of the popular religion with contempt. He was formally accused of impiety in 411, and only saved his life by flight to Pallene, and afterwards to Corinth, where he died. He wrote lyrics and a philosophical work, none of which have been preserved.

Dial and Dialling. A *sun-dial* is an instrument for measuring time by means of the motion of the sun's shadow cast by a stile erected on its surface. It is an instrument of very great antiquity, and before clocks and watches became common, it was in general use as a time-keeper. Some old sun-dials are very elaborate—e.g. that at Glamis Castle, Forfarshire; and many bear quaint mottoes (cf. *Leisure Hour*, 1870, p. 413; and Mrs Gatty's *Book of Sun-Dials*, new ed. 1899). Dial-making was

then an important branch of mathematical study; now it is more an object of curiosity than utility. A dial consists of two parts—the *stile* or gnomon, usually the edge of a plate of metal, always made parallel to the earth's axis, and pointing towards the north pole; and the *dial-plane*, which may be of any hard substance, and on which are marked the directions of the shadow for the several hours of the day, their halves, quarters, &c. Dials receive various names, according mostly to the positions which they are constructed to occupy. When the dial-plane is on the plane of the horizon, the dial is called a horizontal dial; when perpendicular to that plane, a vertical dial. An equinoctial dial is one whose plane is parallel to the equinoctial plane. The south dial, north dial, east dial, west dial, polar dial, declining dial, are named from the position of the dial-plane. The cylindrical dial is a dial drawn on the curved surface of a cylinder. The ring dial is an ingenious small portable dial, but rather a curious toy than a philosophical instrument. A *night or nocturnal dial* is an instrument for showing the hour of the night by the shadow of the moon or stars. Moon-dials may be constructed relative to the moon's motion; or the hour may be found by the moon's shadow on a sun-dial. But because of the irregularity of the moon's motion, due to its varying speed at different parts of its orbit, the time so found is subject to considerable error.

Dialling.—The *stile* of a dial being parallel to the earth's axis, those familiar with spherical trigonometry will readily see that the problem of constructing a dial resolves itself into that of ascertaining where the hour-lines cut a given circle, with a view to the graduation of the dial-plane. Suppose *Pep* (fig. 1), a hollow and transparent sphere, as of glass, to represent the earth; and suppose its equator divided into 24 equal parts by the meridians *a, b, c, d, &c.*, one of them passing through a given place, say London (see HORIZON), at the point *a*. If the hour of twelve be marked at the equator, both on the latter meridian and that opposite it, and all the rest of the hours in order on

Fig. 1.

the other meridians, those meridians will be the hour-circles of London, because, as the sun appears to move round the earth in 24 hours, he will pass from one meridian to another in one hour. Then, if the sphere has an opaque axis, as *Pep*, terminating in the poles *P* and *p*, the shadow of this axis would fall, in the course of the day, on every particular meridian and hour, as the sun came to the plane of the opposite meridian, and would thus show the time at London, and at all other places

on the same meridian as London. If the sphere were cut through the middle by a plane ABCD, in the rational horizon of London, and if straight lines were drawn from the centre, E, of the plane to the points where its circumference is cut by the hour-circles of the sphere, those lines would be the hour-lines of a horizontal dial for London; for the shadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the sphere. Similarly, if we suppose the sphere cut by *any* other plane facing the meridian, the hour-circles of the sphere will cut the edge of the plane in those points to which the hour-lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on these lines at the respective hours. The like will hold of any plane, whether it face the meridian or not, provided it do not coincide with it, or do not coincide with a plane through the poles, and perpendicular to the plane of the equator. In the latter case, the axis would have no elevation above the plane of the dial; in the former, the shadow would not move circularly.

The *universal dialling cylinder*, an invention of Ferguson's, is represented in fig. 2. ABCD is a

Fig. 2.

glass cylindrical tube, closed at both ends with brass plates, on the centres of which a wire or axis, EFG, is fixed. The tube is either fixed to a horizontal board, H, at an angle equal to the latitude of the place, or moves on a joint, so that it may be elevated till its axis is parallel to the earth's at any latitude. The 24 hour-lines are drawn on the outside of the glass, equidistant from one another, and parallel to the axis. The XII next B stands for midnight; the XII next the board, for noon. When the axis is adjusted for the latitude, and the board levelled, with the line HN on the meridian, and the end towards the north, the axis EFG, when the sun shines, will serve as stile, and cast a shadow on the hour of the day among the parallel hour-lines. As the plate AD is parallel to the equator, and EFG perpendicular to it, right lines drawn from the centre to the extremities of the parallels will be the hour-lines of an equinoctial dial, and the axis will be the stile. A horizontal plate, *ge*, if put into the tube, with lines drawn from the centre to the several parallels cutting its edge, will be a horizontal dial for the given latitude; and similarly a vertical plate fronting the meridian, and touching the tube with its edge, with

lines drawn from its centre to the parallels, will be a vertical south dial, the axis of the instrument in both cases serving for the stile; and similarly for any other plate placed in the cylinder. If, instead of being of glass, the cylinder were of wood, any of these dials might be obtained from it by simply cutting it in the planes of the plates, and drawing the lines on the surface of the section.

Dialling sometimes occurs as a term for surveying by help of a compass with sights, such as is called a 'miner's dial,' and is used especially in underground surveys and mine-surveying.

Dialect, in popular language, a local form of speech which differs from the general or received speech of the country, but is manifestly related to it. Still more popularly, dialect is considered to be a 'corruption' of received speech, due to ignorance or carelessness, and is stigmatised as boorish. Both definitions are untenable. The last is so extremely wrong that it would be more correct to term received speech an artificial (as distinct from a natural or organic) 'corruption' of some local form of speech which political or literary circumstances have imposed upon the whole country. The first definition labours under the disadvantage of supposing that there was from the first in any country a received form of speech which 'broke up' into dialects, just as the Latin language actually broke up into the Romance languages of to-day. And this leads to the question, How does a dialect differ from a language? Are the so-called Romance languages not rather dialects of Latin? Is not English collectively a dialect of Low German? Was not Latin itself a dialect of that original Aryan speech which we only know in such dialectal forms as Sanskrit, Greek, Latin, Gothic, &c.? This is a question merely of the meaning we assign to words. It is well fitted for arguing, as Gil Blas argued (chap. i.), but it is of no practical value.

Without going into the very vexed question of the origin of language, we find that wherever two human beings are thrown together a spoken means of communication or language grows up; that wherever a family is isolated a family language is generated; that when the family separates into many distinct families they carry with them some general and various particular forms of the original family speech; that where these families again separate the same process goes on, till the one original speech is broken up into a variety of local forms which differ but slightly from each other, and are usually, though strange, mutually intelligible. Wars, especially civil wars, conquests, defeats, changes of environment due to immigration and emigration, contact with others deriving from a different original family, produce harsher changes, till the groups become mutually unintelligible. It is at this point that the old dialects may be considered to become languages. We have not to go far to seek examples. The slang of each nursery, school, college, profession, and handicraft illustrates the first; the history of Europe furnishes abundant examples of the second. We may therefore have dialects or diversities of related speech without having a received speech at all. In the flourishing time of Greece, Herodotus wrote in Ionic and Thucydides in Attic. There was not even a word for Greek, which, as separate from its dialectal forms, was unknown till long afterwards. In England the author of the first English-Latin dictionary, the *Promptorium Parvulorum*, apologises for writing in East Anglian, as being the only form of speech he knew. It was not till political domination called forth a court speech that the seed of a received speech was sown; but centuries of writers, each touching up the artificial changeling in his own way while using it to express

vigorous thought, were required to build up our glorious English speech.

Dialect, however, is by no means yet extinct, even in England, though railways and school-boards threaten its speedy annihilation. The writer, who has been led to investigate the subject during the last twenty years, finds that we have still six great forms of local speech—Southern, Western, Eastern, Midland, Northern, and Lowland Scotch—further divisible into forty-two districts, each of which has generally numerous varieties. His object was to determine the pronunciation as at present existing all over that part of England and Scotland which is not still Celtic; hence his distinctions are mainly based on pronunciation as referred to the oldest English form of literary speech, the West Saxon or Wessex, which, however, never prevailed over the whole country, and is not even the foundation of modern literary speech. Of this pronunciation he was obliged to omit one striking and characteristic part—viz. the intonation or singsong of speech, which generally strikes a stranger first and most strongly, because he could not invent any practical means of expressing it, and it was very seldom indeed that he could hear it from native uneducated peasants. The two other points to which we must look for distinctions are vocabulary and construction. Vocabulary is the point most generally considered, but it is often delusive as a means of separation, because it is so difficult to trace the area over which certain words prevail as distinct from those where they are not known. The nature of the investigations and their difficulty is well shown in Mr Thomas Hallam's 'Four Dialect Words, Clem, Lake, Nesh, and Oss [= to starve, to play, tender, to offer], their modern dialectal range, meaning, pronunciation, etymology, and early or literary use' (English Dialect Society, 1885). With unusual words, however, or words with unusual significations, most glossarists consider that they are chiefly concerned, while at the same time the difficulty the writers feel in expressing the sounds of the words—i.e. properly speaking, in actually conveying the words—renders their identification uncertain. This is different for literary languages where there is a conventional orthography and pronunciation. The last characteristic mark of dialects is their grammatical construction. It is surprising how little this point is attended to in most glossaries, so that the reader is generally left to discover the construction from the examples, and these in many cases are not sufficiently trustworthy for that purpose. It is the more satisfactory, then, to refer to such glossaries as Elworthy's *West Somerset*, with its separate grammar; Darlington's *Folk-speech of South Cheshire*; Miss Jackson's *Shropshire Word-book*; and Robinson's *Mid-Yorkshire Glossary*, in which pronunciation and grammar are well attended to, and examples are numerous and trustworthy.

In making the above division of English dialects, considered as new local forms of speech referred to one old local form, the Wessex, without any regard to received speech or spelling, the following are the principal distinctions relied upon, and the areas over which they extend.

(1) *Southern* takes in the whole south of England from Cornwall to Kent, extending northwards on the west to the north of Worcester, south of Warwick and Northampton, eastwards to the boundary of Oxford, and all south of the Thames. The marked characters are found in the western half, which die off eastwards, while westwards they exhibit signs of Celtic influence. Wilts, Dorset, Somerset, and Gloucester show this form in its prime. These were the seat of the West Saxon tribes, and best preserve the mark of their origin.

The main character of all the southern division is the pronunciation of *r*, especially where not before a vowel, as in *there, sir!* The *longue*, in the principal region, is reverted, that is, turned with its underside to the hard palate, and its point directed towards the throat. This is the English form of the (different) glottal *r* of the Low German district. It is not only strong in Wilts, Dorset, and Somerset, but also in Devon (where French *u* may likewise be heard), though it dies out through Cornwall, and in west Cornwall, which has comparatively recently become English, has become that of received speech. In Hampshire and eastwards it becomes milder, but on the whole it is still well marked even in Kent. It is the parent of received English *r*, which is little different from an imperfect *d* when it does not become a simple vowel or is lost. Initial *f* and *s* in Saxon words become *v* and *z*. In construction the speech is peculiar in the general use of *I be* for *I am*, and *we am, you am*, for *we are, you are*; in the general prefix of *a* to the past participle—as *I're a-done*; the periphrastic form of the present tense, as *I do go* for simple *I go*, without any implied emphasis; the use of the accusative *en*, from Wessex *hine*, which is replaced by the dative *him* in literary speech; and in one part of Somerset (near to, but west of, Yeovil) the use of *utch* for the first personal pronoun *I*. In the east of Sussex and in Kent *dc, dis, dat*, &c. may be still heard for *the, this, that*, &c., but this is a comparative modernism.

(2) *Western* comprises most of Monmouth, Hereford, and Shropshire, and shows the influence of the Welsh, which in early times prevailed over them; and Shropshire especially preserves a trilled Welsh *r* which is in remarkable contrast to the southern and midland *r*.

(3) *Eastern* extends over the whole of the counties lying north of the Thames but east of Oxford and Leicester and south of Lincoln, embracing also the East Anglian peninsula of Norfolk and Suffolk, which two counties generally have a pronunciation of *to, do, soon*, as if the vowel were nearly French *u*, much the same as in Devonshire. But this does not extend to the rest of the eastern, which bears a remarkable resemblance to received speech, being indeed that part of the country from which it originated. Essex is especially remarkable for pronouncing *paper* like *piper*, a practice which of late years (subsequently to the time of Dickens and Thackeray) has crept into London, and may be heard from most newsboys. Over Kent, Essex, Suffolk, and Norfolk extends the land of *Wee*, where *w* is used for *v*, but not conversely, as *wine* for *vine*, *wan* (rhyming *man*) for *van*, and so on.

(4) *Midland* occupies the whole middle region of England from the north of the three last named to, roughly speaking, a line drawn from Lancaster Bay on the west to the Humber on the east. The speech of the large tract of country thus included is by no means homogeneous. But the Southerner is at once surprised by the difference in the pronunciation of short *o* and *u* in *come, up*, and similar words, which in the greater part of this region resembles the German *ö* or French *eu* with a dash of *oo* in *foot*, being really a transitional form between the well-known southern and Lowland Scotch sound and the *oo* in *foot*. This last sound, however, prevails in Lincolnshire and the south of Yorkshire. Lincolnshire is remarkable for its fractured or divided vowels, which Lord Tennyson writes with *ü*, but which really sound to a Londoner, and even to a native Lincolnshire man, both of whom vocalise their *r*, as if an *r* were annexed, as *sair, sairnts, deerd, doarnt*, for Lord Tennyson's *saiy, saïnts, deüd, döänt* (= say, saints, dead, don't), and so on. In the extreme north of Lincolnshire *ow* is pronounced *oo*, as *noo, coo, hoose*, for *now, cow*,

house, which is not found at all in the other midland counties, but is an old form now characteristic of northern speech. In the western midland, mid and south Lancashire, Cheshire, Derbyshire, one of the most striking pronunciations arises from the treatment of *ow*, which is pronounced *ou* in the south only, at the south-east of Lancashire and north-west of Derby, becoming the prolongation of *a* in *bat*, *cat* in the south-west of Lancashire, of *a* in *father* in the south of Yorkshire, and south Derby, and like *eye* nearly in Cheshire and north Staffordshire. The word for *she* is *hoo* in south Lancashire, north Derby, and Cheshire, and *shoo* in south Yorkshire. The definite article south of Cheshire, Derby, and Nottingham has the usual English form, but in Cheshire, north Derby, and Lancashire becomes the *th* in *outh* without any vowel, though often assimilated to a preceding *t*, and in south Yorkshire is reduced to a simple *t* without any vowel. In construction the most remarkable feature is the verbal plural in *-en* in the present tense, often singularly contracted. Thus *an yo?* is *have-n you?* *dun they* (with the peculiar *u*) is *do-en*, 'do they'; *they known*, *they know-en*, 'they know,' and so on. This prevails in Lancashire, Cheshire, Derbyshire, and the parts of Yorkshire adjoining, but is lost in most of south Yorkshire. It has disappeared recently in Nottinghamshire, is rare in the south midland, and practically disappears in Leicester. *I am* is used in this region, in contrast to the southern *I be*. The *r* is very light and quite different from the southern reverted *r* and the Scotch strongly trilled *r*.

(5) *Northern* extends from the northern boundary of the midland to Scotland. Here *ow* becomes *oo* completely in most of Yorkshire, but remains in the first stage of transition from *oo* to *ow* in Cumberland and Westmoreland. The short *u* in *but*, *cut*, is *oo* in *foot*. The vowels are much fractured or divided throughout north Lancashire, Cumberland, Westmoreland, and Yorkshire, but differently from the forms found in Lincolnshire, the sound of *ee* or *eu* in *beer*, *beur*, being prefixed. In the south-eastern part long *i* becomes *a* in *father*, which is not the case in the south-western part. The definite article becomes simple vowelless *t* (being quite lost in Holderness, Yorkshire) up to a sinuous line through north Cumberland and south Durham, after which the usual form *the* is resumed and continued to the Scotch border. Instead of *I am*, *I is* is regularly used, at least till *the* is restored, and then generally *I am* is heard. In Northumberland a transition occurs from the short *oo* in *foot* in such words as *cut*, *up*, through a sound more resembling German *ö*, and only slightly different from midland short *u*, to the regular southern and Scotch form which is established about Wooler. But the great peculiarity of Northumberland is the uvular (or as it is usually called, guttural) pronunciation of *r*, almost as in the north of France and Germany. This is apparently of recent origin, and hardly overlaps the county border on the south, while it is not heard beyond Berwick on the north. The neighbouring Scots cannot pronounce it.

(6) *Lowland Scotch* pervades all Scotland where Gaelic is not the common language—i.e. generally the south and east, including the Orkneys and Shetlands. Historically, the English language was transplanted into Scotland from the east of Yorkshire and Northumberland, but it now differs materially from the speech there used. The speech in the south of Scotland is probably the most ancient form. (See Dr J. A. H. Murray's *Dialect of the Southern Counties of Scotland* (1873), which is the classical work on the subject.) Phonetically, the southern form is remarkable for retaining *ow* when not followed by a consonant, and using *oo*

when a consonant follows, as *cow*, *hoose*, whereas in the rest of Scotland they have *coo*, *hoose*, as in Yorkshire. Grammatically, it is remarkable for distinguishing the present participle from the verbal noun, both confounded as *-ing* in modern English, as *dansin* in *dansin shoes*. As the English proceeded north to Edinburgh and round to the north of the Forth, this and other distinctions were lost. It is the middle Lowland Scotch, which subsequently spread to the west and south, that is usually known as Scotch by Englishmen, through Burns and Scott in modern times. It was a highly cultivated variety, but was always considered to be English by its older writers. North Lowland Scotch lies north of the Tay, and has the well-known peculiarity of using *f* for *wh*, and in Caithness there is the reduction of the definite article to its vowel *e* alone. The Orkneys and Shetlands are Lowland Scotch engrafted on Norwegian, or Norn, as they term it—i.e. old Norse, which has occasioned many peculiarities both of pronunciation and construction, of which the general, but not universal, use of *d*, *t*, for the two sounds of *th* in *the*, *teeth*, need only be mentioned. For the evidence on which the above divisions are founded, with complete details and examples, the reader is referred to Alexander J. Ellis's *Existing Phonology of English Dialects* (1889), forming Part V. of his *Early English Pronunciation*.

The above remarks refer to the existing forms of speech. Dr Morris in his prefaces to *Hampole*, *Alliterative Poems*, *Dan Michel*, &c., has endeavoured, from the MSS., to determine the characteristics of our dialects in the Early English period. He admits only three—southern, midland, and northern, but divides the midland, 'which presents us with no one typical form,' into west and east midland.

All languages present a variety of local forms, which has just been partially illustrated for English; and in many of these the discrepancies are much greater than in English. Prince Louis-Lucien Bonaparte has done much not only with the English, but with the Basque, French, and Italian forms; for the last, see also Papanti's collection, *I parlari Italiani in Certaldo* (1875). The dialects of Low German have been treated by J. Winkler in his *Dialektikon* (1874). The Swedish dialects are being especially studied now. The High German and Swiss dialects have received much attention. Schmeller's *Bavarian Dialects* (*Mundarten Bayerns*, 1821) is a remarkable work. And so on.

Now to what end or purpose is this study of dialects pursued? They possess comparatively no literature having any attraction in itself. The modern forms are spoken only by the illiterate, and sound uncouth and harsh to an educated ear. They are not pursued for the ideas which they convey, but for the manner in which they convey them. They lead us to understand how a received or literary language was formed. They contain multitudes of 'missing links,' which serve to explain relations which might otherwise entirely baffle the student of language. Thus, there are two old forms, then pronounced as the present long *ee* and *oo*, which now appear as long *i* and *ow*. How did this come about? It is evident that the people could not have suddenly left off one and taken up another. Now the actual transitional forms still exist, like fossils, in dialectal speech. Modern philology obliges us to leave the merely written forms and study living usages. This is only possible by studying existent local forms of speech, in other words, dialects.

There is a considerable literature of modern English dialects, but it labours under the disadvantage of generally not being genuine—i.e. not

due to dialect speakers themselves, and when so due, as in Burns's poems, it is too apt to be unduly mixed up with modern received speech. Naturally, the born dialect speaker is not a literary man, as the writer of dialect works inevitably is. Some of the best pieces of Cumberland speech (Gibson) and High Furness dialect (Piketah = Barber) have been written by men who had lived only a few years in the country, and had been attracted by the curious forms of the speech among which they came. Others seem to have been written purely 'from the fun of the thing,' such as the Essex 'Tiptree Fair' and 'John Noakes and Mary Stiles,' and the Kent 'Dick and Sal.' One of the few modern books written with a desire to show the better side of the dialect as distinguished from its ludicrous side is the late Rev. W. Barnes's Dorsetshire poems. There are also many serious Cumberland poems given by Gilpin. Nathan Hogg's (Baird's) poems and the *Exmoor Scolding*, as edited by Elworthy, with the pronunciation and notes, deserve study as the work of natives. The legion of Lancashire and Yorkshire books is chiefly rollicking. But *Tim Bobbin* has become a classic. In Northumberland the *Pitman's Pay* takes a similar position. Both have influenced the orthography used by other writers. In Scotland, besides Burns and Scott, must be mentioned the excellent Aberdeenshire *Johnny Gibb of Gushetneuk*, and the same writer's *Life among my ain Folk*. Dennison's *Orcadian Sketch Book* is also first-rate. The *Bibliographical List* of works relating to dialects, including both glossaries and examples, published by the English Dialect Society, which was founded in 1873, contains 200 pages, and to this and the other publications of this meritorious society the reader is referred for further information.

Dialectic is a Greek word which signified originally 'the art of rational conversation,' but came to have a technical signification in the language of philosophy. At first it implied a regular and scientific method of treating general conceptions or general terms—a sort of anatomy of names, and through them of the things denoted. In the Socratic philosophy, and more especially in that of Plato, dialectic was thus the method of the highest and deepest kind of speculation. Aristotle gave another signification to the word. According to him, a scientific proof or deduction is different from a dialectic proof, which is only a probable deduction. After this, dialectic came round to imply a kind of fencing in words, the art of so using the forms of reasoning as to confound your opponent, and make fallacies pass for truth. Dialectic is sometimes used as synonymous with logic. The Hegelian philosophy regards dialectic as at once the method of knowledge and of the evolution of the universe itself.

Di'allage (Gr. *di'allagē*, 'interchange;') so called from its changeable colour, a mineral nearly allied to Augite (q.v.), and by some regarded as a variety of it. Its chemical composition is essentially the same. It is seldom found perfectly crystallised, but usually massive, granular, or disseminated, and is characterised by its markedly laminated structure. It is brown, gray, or green in colour, but shows a kind of metallic lustre when broken across the cleavage. This is due to the presence of microscopic tubular inclusions or leaflets, which are disposed parallel to the cleavage-planes or laminae. Di'allage is a rock-forming mineral of some importance, occurring as a primary constituent of Gabbro (q.v.).

Dialogue, a conversation between two or more persons, implying, however, greater unity and continuity of subject than an ordinary conversation. The ancient Greek philosophers were fond of this

way of conducting their investigations and conveying their instructions. The Socratic dialogue is a conversation in the form of question and answer, so contrived that the person questioned is led himself to originate those ideas that the questioner wishes to bring before him. The dialogues of Plato are, as it were, philosophical dramas, in which the Socratic method of investigation is brought to bear upon speculative subjects. One of the greatest masters in this form was Lucian, whose keen-edged and brilliant wit was especially adapted to it. The dialogue is but ill adapted to the exposition of modern science, although elementary hand-books in the form of question and answer are still useful as supplying the student with a series of concrete facts tersely expressed. Of the more eminent modern writers of the literary forms of dialogue, we may mention Erasmus in Latin; Lessing, Herder, and Wieland among the Germans; Petrarch and Machiavelli in Italy; Fénelon, Fontenelle, and Diderot in France; and in England, Berkeley, Swift, Hurd, Harris, Helps, and Landor in his *Imaginary Conversations*. Dialogue combined with action gives us the drama.

Dialysis. See OSMOSE, DIFFUSION.

Diamagnetism. Bodies such as iron, when placed in a field of magnetic force, tend to move from places of weaker to places of stronger force. The opposite is true of bismuth and other substances. Such substances are said to be *diamagnetic*. For further information, see MAGNETISM.

Diamantina, an episcopal town, of mean appearance, in the Brazilian province of Minas Geraes. It is the centre of a rich diamond district, and has manufactures of cotton and goldware. Pop. 13,000.

Diameter, in Plane Geometry, is generally a straight line bisecting any system of parallel chords of a conic section. The lines which it bisects are termed its *ordinates*. In the circle, ellipse, and hyperbola, every diameter passes through the centre of the curve, and is there bisected; but it is only in the case of the circle that all diameters are equal. In the parabola, since the centre of the curve is at an infinite distance, all diameters are parallel to the axis.

Diamond (corrupted from *adamant*, q.v.), a natural form of crystallised carbon, highly valued as a precious stone, but of much less value than the ruby. The diamond crystallises in the cubic or monometric system, its common forms being the regular octahedron, the rhombic dodecahedron, and the six-faced octahedron. The faces are often curved, and the general form of the crystal is more or less rounded. Cleavage is perfect, parallel to the faces of the octahedron—a fact which is often taken advantage of in splitting off fragments for the purpose of removing flaws. The surface of the diamond frequently exhibits striae and triangular impressions, while the interior may contain microscopic cavities and various inclusions. A distinctly lamellar structure is by no means uncommon.

The lustre of the diamond is peculiar to itself, and hence termed 'adamantine.' In a natural condition, however, the surface often presents a dull lead-gray semi-metallic lustre. The high refractive and dispersive powers of the diamond produce, when the stone is judiciously cut, a brilliancy and 'fire' unequalled by any other stone. The mean index of refraction is 2.4, and the angle of total reflection about 24° 24'; the latter accounts for the lustre, inasmuch as a large proportion of the incident light is in a well-cut diamond reflected from the inner surface of the stone. The diamond, especially when coloured, is highly phosphorescent, that is to say, after exposure to brilliant illumination it emits the rays which it has absorbed, and

thus becomes self-luminous in the dark. Under the electric discharge in a highly-rarefied medium it exhibits beautiful phosphorescent phenomena, as pointed out by Mr Crookes.

The specific gravity of the diamond is about 3.52, and its degree of hardness greater than that of any other mineral, being indicated by 10 in the ordinary scale. The excessive hardness serves to distinguish the diamond from other gem-stones: any stone which readily scratches ruby and sapphire must be a diamond. Notwithstanding its hardness the diamond is brittle, and hence the absurdity of the ancient test which professed to distinguish the diamond by its withstanding a heavy blow struck by a hammer when placed on an anvil.

Regarded formerly as a peculiar kind of rock-crystal, the chemical composition of the diamond remained for a long time extremely obscure. It was shown by the Florentine academicians Averani and Targioni, about 1695, that the diamond could be volatilised at a high temperature, their experiments having been made at the cost of the Grand-duke Cosmo III.

Newton in 1704 expressed the opinion that the diamond, from its high refrangibility, was probably an unctuous body coagulated. In 1751 the Emperor Francis I. performed an experiment which showed that diamonds strongly heated in a furnace completely disappeared. Towards the latter part of the 18th century several French experimentalists, including Darcet and Macquer, examined the behaviour of diamonds at a high temperature; but it was reserved for Lavoisier in 1772 to demonstrate that while the diamond is extremely refractory if heated with total exclusion of air, it is readily combustible at a moderate temperature in the presence of air or oxygen, with production of carbonic acid gas. In 1797 the English chemist Smithson Tennant satisfactorily showed the identity of diamond with carbon. In recent years highly refined researches on this subject have been made by Dumas, Stas, Roscoe, and Friedel, all tending to prove that the diamond is practically pure carbon. Chemists have generally experimented, for sake of economy, with impure specimens, and have thus obtained on combustion a considerable amount of ash, the nature of which has not been well ascertained. It has been shown, however, that the purer the diamond the smaller is the proportion of ash left on its combustion. Gustav Rose, shortly before his death, subjected diamonds, inclosed in a vessel free from air, to the intense heat of the voltaic arc produced by a powerful dynamo constructed by Siemens of Berlin. Under these circumstances the gems became gradually incruusted with a dark coating of graphitic matter, and in some cases triangular depressions were developed on the faces, similar to those often observed in the South African diamond in its natural state.

As the chemical composition of the diamond is well known, it has often been supposed that carbon might be induced by artificial means to assume the characters of the gem. In 1880 J. B. Hannay of Glasgow announced that he had succeeded in producing artificial diamonds by inclosing a mixture of paraffin spirit and bone-oil distillate, with metallic lithium, in a strong wrought-iron tube, and exposing it to prolonged heat in a reverberatory furnace. Specimens of diamantoid carbon were thus obtained, but of small size, and it was found that these, when placed on the wheel, immediately crumbled. As the experiments offered no promise of commercial success, and were of so difficult and dangerous a character, they have not been repeated.

It is notable that the occurrence of diamonds has been recorded in a meteorite. Jeoffroy and

Latchinoff in examining the meteorite which fell on September 22, 1886, near Novi-Urei, government of Penza, South-east Russia, detected the presence of about 1 per cent. of diamantoid carbon.

An imperfect variety of diamond known as *bort*, or *boart*, occurs in the form of small spherical concretions with crystalline texture. Although unfit for use as an ornamental stone, it is employed when ground as an abrading agent; and the powder mixed with oil serves to feed the lapidary's wheel when cutting hard stones. Much of the *bort* of commerce is not the mineralogical variety, but consists of splinters, rough fragments, and imperfect crystals of ordinary diamonds. The diamonds used by the glazier for cutting glass are ordinary crystals with rounded faces, and are known as *vitré* diamonds. The cut, though only to the depth of about the $\frac{1}{16}$ th of an inch, is sufficient to determine with precision the direction in which the glass shall break.

Carbon, or *carbonado*, is the name applied to an opaque, black, granular, or imperfectly crystallised variety of diamond found only in Brazil, where it was discovered in 1843. While its density is less than that of crystallised diamond, its hardness is much greater, and hence it is used in the arts, especially for mounting in the steel heads or crowns of the rotary diamond drills for rock-boring.

The art of cutting and polishing the diamond is said to have been discovered in 1456 by Louis de Berguem of Bruges. As now practised, the stone is first, if necessary, cleaved or split, and then 'bruted' or rubbed into shape. The faces of the stone thus 'cut' are ground and polished on flat metal discs, fed with diamond dust and oil, and revolving with great rapidity by steam-power. Amsterdam is the chief home of this industry, and the trade is chiefly in the hands of Jews; but diamond cutting and polishing are also now extensively carried on in London, Antwerp, &c. The common form of the diamond is either the *brilliant* or the *rose cut*. The brilliant resembles two truncated cones, base to base, the edge of the junction being called the *girdle*, the large plane at the top

Fig. 1.—Square-cut Brilliant.

is the *table*, and the small face at the base the *culet*; the sides are covered with symmetrical facets. Fig. 1 shows a square-cut brilliant, and fig. 2 a round-cut brilliant. The rose has a flat

Fig. 2.—Round-cut Brilliant.

base, with sides formed of rows of triangular facets rising as a low pyramid or hemisphere; but this form of diamond is daily becoming less fashionable, and is therefore of comparatively little value. It is illustrated by fig. 3.

India was formerly the only country which yielded diamonds in quantity, and thence were obtained all the great historical stones of antiquity. The chief diamond-producing districts are

those (1) in the Madras presidency, on the Kistna and Godavari rivers, commonly though improperly termed the Golconda region; (2) in the Central

Fig. 3.—Rose-cut Diamond.

Provinces, including the mines of Sumbulpur; and (3) in Bundelkhand, where the Panna mines are situated.

At present the diamond production of India is insignificant. It is notable, however, that in 1881 a fine diamond, weighing 67½ carats, was found near Wajra Karur, in the Bellary district, Madras. The stone was cut into a brilliant weighing 24½ carats, and is known as the 'Cor-do-Norr.'

Brazil was not regarded as a diamond-yielding country until 1727, when the true nature of certain crystals found in the gold washings of the province of Minas Geraes was first detected. Diamonds occur not only in this province, but in Bahia, Goyaz, Matto Grosso, and Paraná. The geological conditions under which the mineral occurs have of late years been carefully studied by Professors Derby, Gorceix, and Chatrian. The diamonds are found in the sands and gravels of river-beds, associated with alluvial gold, specular iron ore, rutile, anatase, topaz, and tourmaline. In 1853 an extraordinary diamond was found by a negress in the river Bogagem, in Minas Geraes. It weighed 254½ carats, and was cut into a brilliant of perfect water, weighing 125 carats (see fig. 4, b). This brilliant, known as the 'Star of the South,' was sold to the Gaikwar of Baroda for £80,000.

Both the Indian and the Brazilian diamond-fields have of late years been eclipsed by the remarkable discoveries of South Africa. Although it was known in the last century that diamonds occurred in certain parts of South Africa, the fact was forgotten, and when in 1867 they were found near Hopetown, the discovery came upon the world as a surprise. The principal mines are situated in Griqualand West, but diamonds are also worked in the Orange River Free State, as at Jagersfontein. The stones were first procured from the 'river diggings' in the Vaal and Orange rivers. These sources have occasionally yielded large stones; one found in 1872 at Waldeck's Plant on the Vaal weighed 288½ carats, and yielded a fine pale yellow brilliant, known as the 'Stewart.'

It was soon found that the diamonds of South Africa were not confined to the river gravels, and 'dry diggings' came to be established in the so-called 'pans.' The principal mines are those of Kimberley, De Beer's, Du Toit's Pan, and Bultfontein. At these localities the diamonds occur in a

serpentinous breccia, filling pipes or 'chimneys,' generally regarded as volcanic ducts, which rise from unknown depths and burst through the surrounding shales. The 'blue ground,' or volcanic breccia containing fragments of various rocks cemented by a serpentinous paste, becomes altered by meteoric agents as it approaches the surface, and is converted into 'yellow earth.' At Kimberley the neighbouring schists, or 'reefs,' are associated with sheets of a basaltic rock, which are pierced by the pipes. In the year 1887 the production of the principal mines was as follows:

	Weight in Carats.	Value.
Kimberley.....	1,333,832	£1,410,207
De Beer's.....	1,014,048	1,022,878
Du Toit's Pan.....	686,576	987,283
Bultfontein.....	602,246	612,862
St Augustine.....	197	250
	<hr/> 3,646,899	<hr/> £4,033,580

The great number of large stones found in the mines of South Africa, as compared with those of India and Brazil, is a striking peculiarity. In the earliest days of African mining a diamond of about 83 carats was obtained from a Boer. This stone when cut yielded a splendid colourless brilliant of 46½ carats, known as the 'Star of South Africa,' or as the 'Dudley,' since it afterwards became the property of the Countess of Dudley. Some of the

Fig. 4.

a, Great Mogul; b, Star of the South; c, Koh-i-nur; d, Regent; e, Orloff—all actual size.

African stones are 'off coloured'—i.e. of pale yellow or brown tints; but a large gem of singular purity was found at Kimberley in 1880. This is the famous 'blue-white' diamond of 150 carats, known from the name of its possessor as the 'Porter Rhodes.' See CAPE COLONY.

It has long been known that diamonds occur in Australia, but hitherto the Australian stones have been all of small size, and it is notable that these are much more difficult to cut, being harder than other diamonds. Although Victoria and South Australia have occasionally yielded diamonds, it is New South Wales that has been the principal producer. The chief diamond localities have been near Mudgee, on the Cudjegong River, and near Bingera, on the river Horton.

Borneo also yields diamonds. The stone known as the 'Matan' is said to have been found in 1787 in

the Landak mines, near the west coast of Borneo. It is described as being an egg-shaped stone, indented on one side, and weighing, in its uncut state, 367 carats. Great doubt, however, exists as to the genuineness of this stone, and the Dutch experts who examined it a few years ago pronounced it to be simply rock-crystal. Among other diamond localities may be mentioned the Ural Mountains and several of the United States. The largest diamond yet recorded from North America was found at Manchester, Chesterfield county, Virginia. It weighed 23½ carats, and yielded, when cut, a brilliant known as the 'Ou-i-nur,' which weighed, however, only 11½ carats.

A few special diamonds, from their exceptional size or from the circumstances of their history, deserve notice. Of all the great diamonds, the 'Koh-i-nur' is perhaps the most interesting (see fig. 4, c). While tradition carries it back to legendary times, it is known from history that the Sultan Ala-ed-din in 1304 acquired this gem on the defeat of the Rajah of Malwa, whose family had possessed it for many generations. In 1526 it passed by conquest to Humaiun, the son of Sultan Baber. When Aurungzebe subsequently possessed this stone, he used it as one of the eyes of the peacock adorning his famous peacock throne. On the conquest of Mohammed Shah by Nadir Shah in 1739, the great diamond was not found among the Delhi treasures, but learning that Mohammed carried it concealed in his turban, Nadir, on the grand ceremony of reinstating the Mogul emperor on the throne at the conclusion of peace, offered to exchange turbans, in token of reconciliation, and by this ruse obtained possession of the gem. It was when Nadir first saw the diamond on unfolding the turban, that he exclaimed, 'Koh-i-nur,' or 'Mountain of Light,' the name by which the gem has ever since been known. At Nadir's death it passed to his unfortunate son, Shah Rokh, by whom it was ultimately given to Ahmed Shah, the founder of the Durani Afghan empire. By Ahmed it was bequeathed to his son, Taimur Shah; and from his descendants it passed, after a series of romantic incidents, to Runjit-Singh. On the death of Runjit, in 1839, the diamond was preserved in the treasury of Lahore, and on the annexation of the Punjab by the British in 1849, when the property of the state was confiscated to the East India Company, it was stipulated that the Koh-i-nur should be presented to the Queen of England. It was consequently taken in charge by Lord Dalhousie, who sent it to England in 1850. After the Great Exhibition of 1851, where it had been exhibited, it was injudiciously re-cut in London by Voorsanger, a skilful workman from Messrs Coster's factory at Amsterdam. The re-cutting occupied 38 days of 12 hours each, and the weight of the stone was reduced from 186½ to 106½ carats. The form is that of a shallow brilliant, too thin to display much fire. According to Lady Burton, it is believed to bring ill-luck to its possessor.

Another famous Indian diamond is the 'Great Mogul' (fig. 4, a), which appears to have been found about 1650, in the Kollur mine, on the Kistna. It was seen by the French jeweller Tavernier at the court of Aurungzebe in 1665, and is described as a round white rose-cut stone of 280 carats. Its subsequent history is unknown, and it is probable that at the sacking of Delhi by Nadir Shah in 1739 it was stolen and broken up. Some authorities have sought to identify the Great Mogul with the Koh-i-nur, and others with the Orloff.

The 'Orloff' (fig. 4, c) is an Indian stone which was purchased at Amsterdam in 1776 by Prince Orloff for Catharine II. of Russia. The stone at one time formed the eye of an idol in a temple in the island of Seringham, in Mysore, whence it is said to have

been stolen by a French soldier. It weighs 193 carats, and is mounted in the imperial sceptre of the Czar.

The 'Regent' is a famous diamond preserved among the national jewels in Paris. It was found in 1701, at the Pârtéal mines, on the Kistna, by a slave, who escaped with it to the coast, where he sold it to an English skipper, by whom he was afterwards treacherously killed. Thomas Pitt, grandfather of the first Earl of Chatham, at that time governor of Fort St George, purchased the stone, and had it re-cut in London, whence it is often known as the 'Pitt.' Its original weight was 410 carats, but it was reduced in cutting to 136½; the result, however, was a brilliant of fine water and excellent proportions. Pitt sold it in 1717, through the financier John Law, to the Duke of Orleans, then Regent of France during the minority of Louis XV. The price paid was £135,000, and its value has since been estimated at £480,000 (see fig. 4, d).

The large 'Sancy' is an historical diamond, about which many contradictory stories have been told. It appears that the Sancy was an Indian stone, purchased about 1570 by M. de Sancy, French ambassador at Constantinople. It passed temporarily into the possession of Henry III. and Henry IV. of France, and was eventually sold by Sancy to Queen Elizabeth of England. By James II. it was disposed of to Louis XIV., about 1695, for £25,000. At the beginning of the 19th century it passed to the Demidoff family in Russia, and by them it was sold in 1865 to Sir Jamsetjee Jeejeebhoy. In 1889 it was again in the market, the price asked being £20,000.

Of coloured diamonds there are a few possessing historical interest. Diamonds occur of all tints, and when the colour is well pronounced, they are prized as fancy stones. A pale green diamond, weighing 48½ carats, is preserved in the Green Vaults at Dresden. But one of the most superb coloured diamonds at present known is the sapphire blue brilliant termed the 'Hope' diamond, valued at £20,000 to £30,000. This gem formerly belonged to Mr H. T. Hope, and weighs 44½ carats. It is believed to have been cut from the large blue diamond, weighing in the rough 112½ carats, sold by Tavernier to Louis XIV., which disappeared amid the troubles of 1792. The two most wonderful coloured diamonds known after the Hope are an emerald green diamond of 6 grains, which is valued at £1000, and a ruby red diamond of 5 grains, valued also at £1000.

For further information on historical diamonds, see *The Great Diamonds of the World*, by E. W. Streeter (1882); and on diamonds generally, consult *Precious Stones and Gems*, by the same author (4th ed. 1884); *Le Diamant*, by H. Jacobs and N. Chatrian (Paris, 1884); and *Le Diamant*, by E. Boutan (Paris, 1886).

Diamond Beetle. See WEEVIL.

Diamond Harbour, a port and telegraph station on the Hugi, 38 miles SSW. of Calcutta by rail, 41 by river. Formerly, the Company's ships anchored here; now there is not even a village at the spot, but a customs establishment is maintained, and shipping movements are telegraphed to Calcutta.

Diamond Necklace, THE, a wonderful piece of jewelry, made in Paris about the year 1775, and intended for Madame Dubarry, the favourite of Louis XV. She, however, was excluded from court on the death of Louis (1774), before the necklace was finished. After being made, this beautiful ornament, adorned with 500 diamonds, was found to be so costly that no one could purchase it. It was valued at 1,800,000 livres, equal to about £80,000 of modern money.

The Prince Cardinal de Rohan, a wealthy, vain,

and profligate man, persuaded by an adventuress named De Lamotte, who waited about court, that the queen (Marie Antoinette) regarded him with favour, became completely infatuated with the idea. One night in August 1784, the poor dupe had the happiness of a moment's interview in the groves around Versailles with the queen in the person of a girl who closely resembled her. De Lamotte had stated to the cardinal that the queen was desirous of obtaining this glorious necklace, and that not having sufficient money just then, she would sign an agreement to purchase it if the cardinal would become security. The cardinal consented. The agreement was approved of and signed with the royal signature, as also with that of the cardinal, who, on the 1st February 1785, carried off the treasure from the maker to Versailles, where it had been agreed the queen should send for it. In a few days De Lamotte and her husband, having disappeared from Paris, were busily engaged in selling the separate diamonds in the necklace. The whole transaction had been a trick; the messages from the queen, oral and written, were without foundation, the latter, indeed, being forged by a *soi-disant* valet, who was skilled in imitating handwriting. The plot was discovered by means of the maker of the diamond necklace, who, not receiving any money when the period of the first instalment had arrived, went to court, demanding to know if the necklace had been delivered to the queen. In a few months the cardinal found himself in the Bastille, where some of those by whom he had been duped had already been lodged. In May 1786 the trial of the prisoners was brought to a close. De Lamotte was branded on each shoulder with the letter V (for *voleuse*, 'thief'), and was sentenced to perpetual imprisonment. Her husband, who had fled to England, was sentenced in his absence to the galleys for life. The cardinal and the girl who had personated the queen were dismissed without punishment. The queen was falsely supposed by the populace of Paris to have had a part in the plot, and the odium resulting from it was heaped upon her, even at the last, when she sat on the tumbril that bore her through a raging and cursing mob to the guillotine. See Carlyle's somewhat rhapsodical study, which appeared in two successive numbers of *Fraser's Magazine* (1837), reprinted in his *Essays*; also H. Vizetelly's *Story of the Diamond Necklace* (new ed. 1880).

Diana, an ancient Italian divinity, identified by the Romans with the Greek Artemis. She was a goddess of light, and she represented the moon, just as Dianus (Janus) did the sun. It is said that Servius Tullius was the first to introduce her worship at Rome, and apparently she was first worshipped by patricians only. See ARTEMIS.

Diana (1) OF POITIERS, a favourite of Henry II. of France, was born in 1499, the eldest daughter of Jean de Poitiers. Married at thirteen, she became a widow at thirty-two, and ere long attached the affections of the nineteen years younger dauphin strongly to herself. On his accession as Henry II. (1547) Diana enjoyed great influence, did much to reform the court, and brought its influence to bear strongly against the reforming party. She was made Duchess of Valentinois in 1548, retired from court to her castle Château d'Anet on the king's death in 1559, and died in 1566. The splendid Château de Chenonceaux (q.v.) was given her by the king, but after her death was taken by Catharine de' Medici. It still contains many memorials of its most famous mistress.—(2) DIANA OF FRANCE, Duchess of Angoulême, was born in 1538, natural daughter of Henry II. and

a Piedmontese (according to others, of Diana of Poitiers), was formally legitimized, and married first to a son of the Duke of Parma, next to the eldest son of the Constable de Montmorency. She enjoyed great influence at court under Henry IV., superintended the education of the young prince, afterwards Louis XIII., then retired from court, and died without issue in 1619.

Dianthus. See CARNATION, PINK.

Diapa'son (Gr.), a term in music by which the ancient Greeks designated the octave. The French use the term as equivalent to *pitch*. Diapason is also the English name given to the fundamental stops of the Organ (q.v.).

Diaper, a term applied to certain forms of flat or slightly relieved ornament. Any pattern formed of a floral, leafy, geometric, or other device, repeated over a flat surface, is called *diaper* or *diaper work*; but according to some authorities the device should be free from bounding lines forming squares, as a pattern of this nature should rather be called *checker* or *checker work*.

In *textile fabrics* the term appears to have been given at one time to silk fabrics with almost any kind of repeated pattern upon them. It is an older name for figured silk than *Damask* (q.v.). The Byzantine Greeks called a silk with both pattern and ground of one colour *diaspron*, and the Latins, following the Greeks, named such a fabric *diasper*, which by a slight change became the English word *diaper*. Chaucer refers to 'cloth of gold diaped wele' (see *Textile Fabrics*, by the Rev. D. Rock, D.D.). Any kind of textile fabric, paper, or leather, with a more or less enriched geometrical pattern is, in a general way, said to be diapered. But as regards textiles the term *diaper* nowadays is almost confined to undyed linen with a woven diamond pattern, although cotton imitations are made. According to the size of this pattern the stuff is called *bird's-eye*, *pheasant's-eye*, *fish-eye*, or *Russia diaper*.

In Architecture, *diaper-work*, or *diapering*, is a kind of decoration applied to plane surfaces, and consists of a small repeated pattern either of conventional flowers, leaves, or other devices, carved or painted. The flower, or other object, is generally inclosed by lines, fillets, or slender mouldings, which constitute in themselves a sort of geometrical diapering. When the pattern is carved, it is generally sunk; and when painted, it consists of a darker shade of the same colour as the plane surface, by which the effect of shadow is communicated to it.

The accompanying illustration, from Bloxam's *Gothic Architecture*, exhibits a very beautiful example of Decorated English diapering. It is taken from Canterbury Cathedral. In Professor Willis's book on this building other examples are given.

Diaphoretics. See SUDORIFICS.

Diaphragm, or MIDRIF (Gr. *diaphragma*, 'a partition'), is the name applied in anatomy to designate the musculo-tendinous partition which in man and the mammalia generally separates the cavity of the thorax from that of the abdomen. Its general form is that of a *dome* directed towards the chest, the lower part and sides being muscular, while the central or highest portion consists of an expanded tendon. The muscular fibres have an extensive origin from the circumference of the

Diaper.

visceral cavity—viz. posteriorly, a *vertebral* portion arising from the lumbar vertebræ by two pointed processes, or *crura*, of unequal length, and from two fibrous bands, or *arched ligaments*, on each side of the bodies of the vertebræ: laterally, a *costal* portion arising from the cartilaginous and adjoining osseous parts of the lower six ribs; anteriorly, a

The lower part of the Thorax, opened to show the upper side of the Diaphragm from before:

a, sixth dorsal vertebra; b, fourth lumbar vertebra; c, ensiform cartilage; d, aorta; e, esophagus; f, opening for inferior vena cava. 1, 2, 3, trefoil tendon; 4, 5, central portions of diaphragm; 6, right, and 7, left crus of diaphragm.

sternal portion arising from the ensiform cartilage of the sternum, or breast-bone. From these various points the muscular fibres converge to the central, trefoil, or cordiform tendon, which forms the highest part of the diaphragm, and as its name indicates, consists of three lobes. The diaphragm presents three large perforations or *foramina*: one, *quadrilateral*, placed in the highest part of the tendinous centre for the upward passage of the inferior vena cava; one, *oval* in form, surrounded by

muscular fibres derived from the crura, for the passage of the oesophagus and pneumogastric nerves; the third, situated in front of the vertebræ and bounded by tendinous fibres of the crura, transmits the aorta, thoracic duct, and large azygos vein.

The upper surface of the diaphragm is in relation to the pleural membranes which inclose the lungs, and the pericardium which incloses the heart. The latter membrane is intimately connected with the central tendon, which thus forms a fixed floor for the support of the heart. The lower surface, deeply concave in form, is lined by peritoneum, and has in apposition with it the stomach and spleen on the left side, the convex upper surface of the liver on the right side, and the kidneys, supra-renal capsules, and duodenum posteriorly.

When the diaphragm contracts, the arched portion becomes flatter, and the cavity of the chest being thereby enlarged, air rushes in to fill the vacuum, and expands the lungs during the act of inspiration. It is thus an inspiratory muscle, and in ordinary quiet breathing the central tendon on which the heart rests takes no share in this movement. Every contraction of the diaphragm must diminish the abdominal space and compress the abdominal viscera, and hence it aids in the expulsion of the feces and urine.

Spasmodic action of the diaphragm produces hiccough and sobbing. Stoppage of the action of the diaphragm, whether from great external pressure or from paralysis, is very speedily fatal.

DIAPHRAGM, a partition with a hole in it, employed not only in landscape and portrait lenses for photography, but also in telescopes, microscopes, and other optical instruments, for the purpose of cutting off the superfluous rays of light,

and producing greater intensity or sharpness of the image, as well as to correct aberration.

Diarbekir, a town of Asiatic Turkey, capital of a province of the same name, is situated on the right bank of the Tigris, 390 miles NW. of Bagdad. The town is surrounded by high strong walls, and commanded by a citadel built on a high basalt rock, against which the flat-roofed houses rise above each other in terraces. The population has dwindled to 40,000, mostly Kurds and Armenians. The city is the residence of a pasha, and the seat of a Greek bishop, as also usually of the Jacobite patriarch of Antioch. It has 27 mosques and 12 churches, and numerous bazaars, fountains, baths, and caravanserais, although the last are now falling into decay. Indeed, only in the centre of the town are any of the buildings handsome; elsewhere ruins meet one at every step. Stagnant pools, weeds, and filth combine to produce fevers. Diarbekir had formerly extensive manufactures of silk and cotton goods, and an active commerce with Aleppo and Bagdad; and it still has considerable trade in raw products. The roads to the coast are equally bad and insecure, and the traffic with Bagdad is mostly by raft. The principal exports are wool, mohair, sheep and goats, copper ore, butter, gall-nuts, goat and kid skins, and furs; the imports include cotton and woollen goods, indigo, coffee, sugar, buffalo-hides, petroleum, and soap. Diarbekir occupies the site of the ancient *Amida*, which was fortified by the Emperor Constantine. It was captured by the Persians in 359, and retaken by Justinian; but in 502 the Persians once more became masters, and put 80,000 of the inhabitants to the sword. In 640 it fell into the hands of the Arabs of the Bekr tribe, whose name became identified with the district; but the Turkish official title is still *Kara Amid* ('Black Amid,' from the colour of its basaltic walls). After many vicissitudes, the town passed into the hands of Sultan Selim in 1515.

Diarrhœa (Gr. *dia*, 'through,' and *rheō*, 'I flow') is the name applied to an increase in the discharges from the bowels, which are usually unduly liquid, sometimes overcharged with bile, and sometimes the contrary, and is, properly speaking, a symptom rather than a disease. Thus it often occurs in the course of diseases of the liver and spleen, of some forms of heart-disease, of many fevers and other acute diseases, and is a common complication of the advanced stage of Consumption (q.v.). Frequently, however, it is the most prominent, perhaps the only symptom of ill-health; and it may then take rank as a disease, or rather as the generic name of a group of diseases. In this aspect the subject will be discussed here.

Diarrhœa is either simple, bilious, or choleraic; the last form has already been discussed (see CHOLERA). The ancients applied the name *lientery* to a diarrhœa in which the dejections consisted of matters not digested, or very partially so; this form is, however, very unusual, at all events in Britain. Dysentery (q.v.) is also a form of diarrhœal disease; as is the form of Fever (q.v.) called gastric, typhoid, or enteric fever. Simple and bilious diarrhœa probably often differ only in degree; they are both distinguished from the advanced stages of cholera and dysentery by the presence of abundance of biliary colouring matter in the stools, and by the absence of the distinctive features of the other two diseases as described elsewhere. Diarrhœa is almost always accompanied at first by pain in the abdomen, sometimes severe or even agonising in character. According to its cause and treatment, it may pass off in a few hours, or may persist for a few weeks or months; or it may even prove fatal.

Diarrhœa has many varieties and many causes; but the whole tribe of more or less epidemic diarrhœal diseases present certain relations in common, which have been studied of late years to a considerable extent from the preventive or sanitary point of view. Thus it is observed of all of these diseases, without exception, that they are more apt to prevail during summer and autumn than during the earlier seasons of the year; and it is also well established that their prevalence is to a great extent dependent on the intensity of the solar heat, so that a temperature above 60° F. seems to be almost essential, under ordinary circumstances, to their epidemic diffusion. Moreover, it has been shown that the decomposition of organic matters in the neighbourhood of human dwellings, and the introduction of the products of decomposition into the food, drink, or air used by the healthy, has been a direct exciting cause of diarrhœa in a great number of instances where the disease has been locally epidemic; from which it is inferred that the real source of diarrhœal diseases is usually to be found in a morbid poison closely associated with the process of putrefaction, although not, perhaps, necessarily generated during that process. It has been noticed that cold and wet seasons are the least favourable to the production of diarrhœa, which is explained on the theory above alluded to by the rapid removal in such seasons of all organic debris; and there is little doubt that this explanation is correct, as the converse is equally true, the combination of heat with long-continued drought being almost sure to waken into life the epidemic seeds of diarrhœa. Again it is noticed that where drainage is imperfect and drinking water impure, diarrhœal diseases are specially apt to occur (see CHOLERA); the class of the population most apt to be affected being those who occupy low levels, or who are otherwise exposed to the influence of this aqueous or gaseous poison. Infants are especially apt to suffer from diarrhœa, and a large number of the infantile deaths in many English towns are caused either directly by this disease, or by the abuse of stimulants and narcotics for its cure.

Besides these epidemic diarrhœas, isolated cases of simpler and more obvious origin are very frequent. In some persons diarrhœa is the usual result of catching cold—i.e. they suffer from catarrh of the digestive, instead of, as is most usual, the respiratory organs. But far more frequently diarrhœa results from unwholesome or indigestible food or drink, or from excessive indulgence even in what would otherwise not be hurtful. In all such cases the diarrhœa is to be regarded as beneficial; in fact it is the natural effort of the intestines to rid themselves of their objectionable contents, and should be encouraged rather than arrested. Diarrhœa occurring as an incident in prolonged constipation is to be explained in the same way, as due to irritation of the intestines by their hardened contents.

Acute diarrhœa should almost always be treated first by an aperient, as the unaided action of the intestines is often insufficient to expel irritating material. A full teaspoonful of Gregory's powder, or a tablespoonful of castor-oil with ten or fifteen drops of laudanum are especially useful. The food taken should be small in amount, and as easily digestible as possible. Milk, arrowroot, &c., beef-tea, toast, plain biscuits, are among the most suitable articles of diet. Pain may be alleviated by poultices or fomentations sprinkled with laudanum. A small dose of brandy often checks both the pain and the diarrhœa. Should the disease not yield to these measures, opium, carminatives, and astringents should be administered. In some cases, especially of febrile diarrhœa, an emetic of ipecacuanha at the very beginning will sometimes remove the disease

with remarkable rapidity; and in most forms of diarrhœa it may be alleged that this medicine (in doses of from one to five or even ten grains) is well borne. Sometimes it is combined with opium in the form of Dover's powder. In chronic diarrhœa (not the consequence of serious organic disease) careful regulation of the diet is of prime importance, and is generally accompanied by the administration of astringents. But such cases are often very intractable, and no rules can be laid down that would apply to all. In a very large class of cases, especially of infantile diarrhœa, depending upon a too acid state of the secretions, the leading remedy is chalk, either in powder or in the very serviceable form of the *mistura cretæ* (mixture of chalk) of the pharmacopœias, from one to three dessert-spoonfuls of which may be given after every disturbance of the bowels. Lime-water, mixed with milk in the proportion of one to four or five, is easily given to very young children, and serves nearly the same purpose.

The astringents useful in diarrhœa are very various. Those of vegetable origin are usually first employed, alone or in combination. The most important are galls, oak-bark, kino, catechu, log-wood. The mineral astringents are chiefly salts of the heavier metals, iron, bismuth, copper, lead, &c.; but also chalk and lime, and alum. Opium, one of the most powerful remedies, owes its usefulness to other than astringent properties, and is very frequently given in combination with astringents—e.g. in chalk and opium powder, compound kino powder, lead and opium pills. In many states of the system in which diarrhœa occurs, however, it is dangerous. It must never be given to young children, or in large doses to any one, without medical advice. In some forms of diarrhœa, especially in children, antiseptics are very useful—e.g. carbolic acid, creasote; and it is probably to its antiseptic properties that corrosive sublimate (bichloride of mercury) owes its value when administered in minute doses.

Diary (Lat. *diarium*, 'a daily allowance for soldiers,' 'diary,' from *dies*, 'a day') means simply a daily record of events or observations made by an individual. In it the man of letters inscribes the daily results of his reading or his meditations; to the mercantile man it serves the purpose of an order or memorandum book; while the physician finds it indispensable as a register of engagements. Diaries in many forms and sizes are issued every year, containing also so much miscellaneous information that in one book we have at once a diary and an almanac. The *Ephemeris* of the ancients was originally a military record or journal, a day-book or account-book, also a collection of tables showing the position of the heavenly bodies, but passed into literature to mean a collection of records of what has happened on the same day in various years, or a mere general name for any form of periodical books or magazines.

Diaries have often furnished the historian with invaluable material, supplying the absence of public records, and furnishing minute and intimate details of manners and of motives that do far more to help us to understand the past than more formal records. Such documents as Robert Baillie's *Journals*, the *Diaries* of Pepys and Evelyn, and the *Journals* of Greville are among the most valuable sources of real history. Bacon says 'in sea-voyages, where there is nothing to be seen but sky and sea, men make diaries; but in land-travel, wherein so much is to be observed, they omit it,' but unhappily this no longer holds of modern travellers.

Diastase is a peculiar ferment developed during the germination of all seeds. An impure solution of diastase may be procured by adding one part of

hot water to two parts of ground malt (see BEER), or freshly germinated barley, and, after standing for a short time, straining through a cloth. The proportion of diastase in malt is not more than 1 part in 500 parts, and yet it performs important functions. Thus diastase has a powerful action upon starch, and at a temperature of 150° F. one part is considered powerful enough to change 2000 parts of starch into dextrine, and then into maltose, a variety of sugar. When obtained separately, diastase is a white tasteless substance, soluble in water and in weak alcohol, and having no action on gum or sugar. A similar principle is found in the saliva of animals, the action of which on starch is identical with that of diastase. When bread is masticated, the saliva is rapidly secreted, and the animal diastase converts the starch into sugar. See GERMINATION, COOKERY, DIGESTION.

Diathermancy. See HEAT.

Dia'thesis (Gr. *dia*, 'through,' and *tithēmi*, 'I place or arrange'), a Greek word signifying a disposition or arrangement, and applied by the old medical authors to the predisposition or constitution of the body which renders it prone to certain diseased states. By recent writers the term is applied to the general constitutional tendency of an individual, to indicate not merely the class of diseases to which he is most likely to be liable, but also in many cases the manner in which his normal functions, both bodily and mental, are carried on; and is thus opposed to Cachexia (q.v.), an unhealthy condition associated with actual disease. Though the study of diathesis apart from existing disease is very apt to lead to over-refinement and the pursuit of intangible abstractions, yet a proper appreciation of a person's constitutional proclivities or diathesis often enables a medical man to advise him how to regulate his life and habits to the best advantage—what to do and what to avoid—and may furnish important guidance as to his treatment in disease. The diatheses most usually recognised are the sanguine, the nervous or neurotic, the bilious, the lymphatic, the strumous, and the hæmorrhagic. Numerous mixed varieties are also described by some writers.

Diatoms (*Diatomaceæ*) are a group of algae which, on account of their microscopic interest and geological importance, have acquired an unusual share of scientific and even popular attention. They were discovered by Leewenhoek in 1702, and their movements by O. F. Müller eighty years later; their thorough investigation, however, has only become possible with the development of the compound microscope.

The reader who wishes to view the diatoms other than as mere microscopic marvels must begin with a clear grasp of the structure and mode of life of the filamentous conjugate algae, such as *Spirogyra*, and next observe that of those higher members of the group which we know as Desmids (see ALGÆ, DESMIDS). These simpler forms understood, let him next imagine a desmid (in which the characteristic division of the unicellular body into halves is distinctly but not too deeply marked) to become somewhat unequally developed; next let these be pressed together so that the larger half slides a little way over the smaller, much like the lid of a canister or the halves of a pill-box. Let the two halves or shells of the cell-wall now become strongly silicified, the cellulose only remaining unaltered and flexible round the narrow 'girdle band' connecting them; next let variation arise in the general shape so that the original box-shape becomes elliptical or wavy, squared, or more often pointed, or even unsymmetrically curved; finally, let the siliceous shells become covered with the most delicate

striations and markings, and these characteristically varied, not only from group to group, but from species to species. A gelatinous envelope may also be developed, or this may be secreted at one pole only, forming a stalk.

The living protoplasm shows less variation than might perhaps have been expected; it lines the siliceous shell, leaving a large central sap-cavity, often traversed by protoplasmic filaments. Very commonly, however, this is divided by a large central mass of protoplasm usually containing the nucleus, while similar accumulations may be formed

Fig. 1. *Pinnularia viridis*: 1. a, Optical section through the unequal valves; b, side of one valve, showing markings and longitudinal slit. 2. Diagrammatic transverse section; pp, protoplasm containing endochrome-plates, ep; g, girdle band. Valves left unshaded, the left showing depressions due to markings.

at the ends. The colouring matter may occur in minute granules, or be collected into one or two large 'endochrome-plates'; it consists of chlorophyll, masked by a closely allied yellow pigment (*phycozanthin*). Starch is absent; oil is frequently present, either in minute vacuoles or collected into a single large drop.

The mechanism of the peculiar creeping or rather gliding movements has long baffled investigators; these, however, are not due to diffusion currents as some have maintained, nor to the agency of any ordinary cilia or pseudopodia, but seem to be effected by means of a locomotor band of protoplasm which is said to be protruded through a longitudinal slit in the surface of the siliceous shells (see fig. 1).

The mode of multiplication is primarily by division, and is effected on the same principle as in Desmids (q.v.). Thus the two halves of the diatom are not only of unequal ages, but since the new half is always formed within the previous one, a continuous diminution of size takes place. At a certain limit, however, division stops, and rejuvenescence may occur, with formation of a resting spore; more frequently, however, this is preceded by conjugation as in desmids, though sometimes complete union may not take place. The resultant 'auxospore' has a continuous cellulose coat, but develops within it, by rejuvenescence, a two-shelled diatom of the largest size, which issues to divide in turn.

Of the 2000 species, 400 are fresh-water, the remainder marine. Their distribution is ubiquitous, and the genera and even species seem little dependent upon temperature or climate, many being apparently cosmopolite, and some having been described as occurring in glacier water, yet also in hot springs. Their minute size and resistance to drying favour their distribution in the form of dust; hence the calcination of the dust

which falls upon ships in mid-ocean has been shown to yield an appreciable diatom residue. Every soil which is overflowed teems with them, notably, therefore, that of Egypt; harbour mud often contains one-fourth to one-half its volume of diatom shells, while in many parts of the world there occur strata of purely diatomaceous origin, which are frequently of vast area and considerable thickness. These are in all states of preservation and hardness, from the loose *Bergmehl* of Siberia and Lapland (which still contains so much undecomposed organic matter as to be mixed with flour in times of scarcity) to building stone, and even the extremely hard polishing slates of Tripoli. Diatomaceous deposits were found in Skye in 1886. The diatomite may be used for making dynamite, siliceous glazed paints, steam-pipe casings, &c. Diatoms live in enormous abundance at the surface of the sea in cold, temperate, and arctic latitudes, and the mud of the sea-bottom is hence very largely composed of the shells of dead diatoms, which are falling from the surface in a gentle but unceasing rain. See the *Micrographic Dictionary*, and general manuals; also special monographs—e.g. Castracane's *Diatomaceæ* (*Challenger* Report, 1885).

Diatonic, a term used in the science of music, originally from the Greek, meaning 'by tones,' or 'from tone to tone.' The diatonic species of the ancient Greeks—as distinguished from their chromatic and enharmonic species—formed the foundation of their whole system of music, and was arranged in tetrachords (embryo *scales*) composed of one semitone and two whole tones. In modern music, the term is applied to (1) the natural or normal scale, major or minor, which proceeds mainly by whole tones; (2) the different species of intervals (usually reckoned as fourteen in number) occurring between the various notes of that scale; and (3) music written wholly or for the most part in that scale.

Diaz, or **DIAS**, BARTOLOMEU, a Portuguese navigator of noble birth who flourished during the latter half of the 15th century. His residence at the court of King John II. brought him into contact with many scientific men, among others the German cosmographer Behaim (q.v.). Diaz took a great interest in geographical discovery, and in August 1486 the king gave him the command of two vessels with a view to following up the discoveries already made by Portuguese adventurers on the west coast of Africa. Diaz soon reached the limit which had been attained in South Atlantic navigation, and first touched land in 26° S. lat. Driven by a violent storm, he sailed round the southern extremity of Africa (see CAPE OF GOOD HOPE) without immediately realising the fact, and discovered Algoa Bay. The discontent of his crew compelled him sorrowfully to return; and arriving in Lisbon, December 1487, he was at first greeted with enthusiasm, but soon saw Vasco da Gama preferred before him, and was compelled to act under the latter in the grand expedition of 1497. Vasco da Gama even sent him back to Portugal after they had reached the Cape Verd Isles. Three years after, he joined the expedition of Cabral, the discoverer of Brazil, but was lost in a storm, 29th May 1500.

Diaz, PORFIRIO, President of Mexico. See MEXICO.

Diaz de la Peña, NARCISO VIRGILIO, painter, was born at Bordeaux in 1807, of Spanish parentage, and, left an orphan at the age of ten, was educated by a Protestant clergyman at Bellevue, where a snake-bite occasioned the amputation of a leg. At the age of fifteen he was apprenticed to a porcelain-painter, but he was

ambitious of working in oils, and about 1831 began to exhibit in the Salon. Abandoning his unsuccessful efforts in the direction of history and *genre*, he in time won fame by his landscapes, which he peopled with nymphs, loves, and satyrs. These figures are badly drawn, but as a colourist Diaz ranks highly among the painters of the Romantic school in France, and to colour he was content frankly to sacrifice form. He was also an exquisite painter of flower-pieces. He died at Mentone, 18th November 1876.

Diaz del Castillo, BERNAL, the historian of the conquest of Mexico, was born about the end of the 16th century, and was one of the handful of heroes who accompanied Cortes to Mexico in 1519. He fought through the whole struggle, and afterwards accompanied the heroic young Sandoval on his expedition northwards, and Cortes himself in his expedition to Honduras to punish the defection of his trusted lieutenant, Christoval de Olid. He died in Mexico about 1560. His *Historia verdadera de la conquista de la Nueva España* (3 vols. Madrid, 1632) is invaluable to the historian as a sincere narration by an eye-witness and sharer in the events narrated. With all the ignorance and superstition of its age, it reveals great powers of observation and of vivid and vigorous description; while the rare romantic interest of the story itself, the heroism of Cortes and his companions, and their wonderful deeds and often tragic deaths, make the book a real epic.

Dibdin, CHARLES, musician and poet, was born at Southampton in 1745. He early attracted notice by his singing, and, still a boy, made his literary début in London, by writing and composing an opera called *The Shepherd's Artifice*, produced at Covent Garden Theatre in 1762. He subsequently lived an unsettled life as an actor and composer of stage-music. In 1788 he commenced giving a series of musical entertainments in the city, which acquired a great celebrity; the first of these was entitled *The Whim of the Moment*. After several vicissitudes he withdrew from public life in 1805, the government in 1803 having granted him, in consideration of his literary merits, a pension of £200. The pension was afterwards withdrawn by the Grenville government in 1807, which occasioned Dibdin to return to public life with unfortunate financial results. He died 25th July 1814. Dibdin was an admirable writer of sea-songs, of which he composed nearly a hundred. Neptune, and not Apollo, seems to have inspired him. Though his work nowhere reaches the higher regions of poetry, and even his seamanship has been impugned, yet it is hardly too much to say that he is our first writer of sea-songs, one or two of which have even been taken to the heart by the mariners of England. His verses smack of the briny deep, and reflect with astonishing felicity the easy, childlike virtues and the fearless courage of the conventional British tar. It is known that they helped to man the navy during the great struggle with France, and as he himself says in his autobiography, 'they have been quoted in mutinies to the restoration of order and discipline.' Among Dibdin's happiest pieces are *Poor Jack* and *Tom Bowling*, or *Poor Tom* as it was originally called. See his *Professional Life* (4 vols. 1803), and for his songs the inaccurate edition by G. H. Davidson, with Life by George Hogarth (1842). Dibdin wrote nearly seventy dramatic pieces.—Two of his sons, CHARLES DIBDIN (1768–1833) and THOMAS JOHN DIBDIN (1771–1841) wrote songs and dramas. See *The Dibdins*, by E. R. Dibdin (1888).

Dibdin, THOMAS FROGNALL, the bibliographer, was nephew of Charles Dibdin, the writer of sea-songs, and was born at Calcutta in 1776. He lost

both parents when hardly four years of age, his father's death at sea having given Charles Dibdin the subject for his famous song, *Tom Bowling*. He was brought up by a maternal uncle, studied at St John's College, Oxford, tried law, but took orders in 1804. He proceeded D.D. in 1825. Of his preferences the chief were the vicarage of Exning near Newmarket, and the rectory of St Mary's, Bryanston Square, London. He died 18th November 1847. His first contribution to bibliography was an *Introduction to the Greek and Roman Classics* (1802), which was followed by an unfinished new edition of Ames and Herbert's *Typographical Antiquities* (4 vols. 1810-19); *Bibliomania* (1809); *The Bibliographical Decameron* (1817); *Bibliotheca Spenceriana* (1814-15); *Bibliographical, Antiquarian, and Picturesque Tour in France and Germany* (1821); *The Library Companion* (1824); *Bibliophobia* (1832); *Reminiscences of a Literary Life* (1836); and *Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and Scotland* (1838). All Dibdin's books are valuable and interesting, but whimsical and flip-pant in style, and unhappily abounding in errors. Dr Dibdin was one of the founders of the 'Rox-burgh Club' (1812).

Dibranchiata. See CEPHALOPODA.

Dice (plural of die), small cubes of ivory marked on their sides with black dots, from one to six. The *points* on the opposite sides of the dice should always sum seven—i.e. ace should be opposite to six (pronounced *size*); deuce to cinque (pronounced *sanke*); and trey to quatre (pronounced *kater*). Two dice are called a *pair*.

By 13 Geo. II. chap. 19, 'all games invented or to be invented with one or more die or dice' were prohibited, except backgammon and games played on a backgammon board. Hence hazard is illegal, and also raffles with dice, the latter being also forbidden as lotteries even if dice are not used. By 9 Geo. IV. chap. 18 (1828), a duty of twenty shillings was imposed on every *pair* of dice; in 1862 the duty was abolished.

The invention of dice is attributed to Palamedes (circa 1244 B.C.). But the use of cubes with numbered sides for gambling purposes is probably much earlier.

Dicentra, a genus of Fumariaceae, of which one species, the 'Chinese lantern plant,' *D. spectabilis* (described by Linnæus in 1753, but only introduced from Asiatic into British flower-gardens in

Dicentra spectabilis.

1846), has become a universal favourite on account of its long racemes of drooping, delicate, rosy-pink flowers. In America it is commonly known as 'Bleeding Heart.' It is a herbaceous perennial of

easy propagation. There are several other North American species, one of which, *D. formosa*, is a favourite and very showy garden-plant. Owing, in the first instance, to a misprint, *Dicentra* has been as frequently called *Dielytra*, the original mistake having become consecrated by habit.

Dichlamydeous, a term in botany applied by De Candolle to distinguish those dicotyledonous flowers possessed of both calyx and corolla from his *Monochlamydeæ*, in which not more than one floral envelope is present.

Dichogamy. See FLOWERS (FERTILISATION OF).

Dicho'tomous (Gr., 'divided into two equal parts'), a term formerly vaguely used in botanical description to designate any appearance of branching by forking. Thus the stems of some phanerogams—e.g. mistletoe, doum palm, and many inflorescences—e.g. Caryophyllæ, Begonias—appear forked, while an ordinary fern-frond has no such appearance. The progress of morphological research has, however, shown that true dichotomy—i.e. complete division of the growing point into two lateral apices, is really as characteristic of the development of the fern-frond as of such obviously dichotomous vegetation as that of Selaginella; while conversely the appearance of forking in phanerogams comes about simply by the suppression of the growing point, and the development of two new axes from opposite lateral buds. Outside the cryptogams, indeed, no case of true dichotomy has been described, with the doubtful exception of the roots of cycads. See CRYPTOGRAMS, FERNS, INFLORESCENCE, CYCADS, &c.

Dichroism (Gr. *dis*, 'twice,' *chroma*, 'a colour') is a term chiefly used in Crystallography to designate the property which many doubly-refracting crystals possess of exhibiting different colours when viewed in different directions. It, or the allied term *Dichromatism*, has also been applied to those fluids which appear of different colours when viewed by reflected and refracted light; when seen in thick or thin layers, &c. For example, venous blood, or any blood impregnated with carbonic acid, hydrogen, or nitrogen, appears, when seen in moderately thin layers, to be of a purple colour; while in extremely thin layers it appears green.—For *Dichroite*, see CORDIERITE.

Dick, JAMES, a West Indian and London merchant, who was born at Forres, Morayshire, in November 1743, died 24th May 1828, and left over £113,000 to promote higher learning among the parish schoolmasters of Elgin, Banff, and Aberdeen shires. Examinations were instituted, and those schoolmasters who showed a satisfactory knowledge were awarded from the bequest a sum of money and an annual stipend as long as they continued to hold office and remained efficient. In 1888 the annual value of the bequest was about £4200, and the average payment to each teacher was £31. The influence of the Dick Bequest has been most beneficial in helping to maintain a high standard of education among the masters of country schools. Considerable changes in its administration were recommended by the Educational Endowments (Scotland) Commission in 1887.

Dick, ROBERT, a self-taught Scotch geologist and botanist (1811-66), was a native of Tullibody in Clackmannanshire, and from 1830 a baker in Thurso. His life was written by Dr Smiles (1878).

Dick, THOMAS, a popular religious and scientific writer, was born 24th November 1774, near Dundee. At a very early age he became devoted to the study of astronomy, and at twenty went to the university of Edinburgh with a view to the ministry in the Secession Church. Licensed in 1801, he preached

some time; next kept school for ten years at Methven, and for ten years more at Perth. Meantime he laboured laudably to promote popular education by 'Literary and Philosophical Societies' corresponding closely to the Mechanics' Institutes of later days. His first book was *The Christian Philosopher* (1823), which quickly became popular. Its success led Dick to devote himself to astronomy and literary work in a cottage near Broughty-Ferry, where he set up an observatory. His many books brought him great popularity both in England and America, but very little pecuniary return. In 1847 he received a crown pension of £50, supplemented by a local subscription. He died at Broughty-Ferry, 29th July 1857. His degree of LL.D. was given him by Union College, New York. Other works were *Celestial Scenery* (1837), *The Sidereal Heavens* (1840), and *The Practical Astronomer* (1845).

Dickens, CHARLES, was born at Landport, now a great town, but then a little suburb of Portsmouth or Portsea, lying half a mile outside of the town walls. The date of his birth was Friday, February 7, 1812. His father was John Dickens, a clerk in the navy pay-office, and at that time attached to Portsmouth dockyard. The familiarity which the novelist shows with seaports and sailors is not, however, due to his birthplace, because his father, in the year 1814, was recalled to London, and in 1816 went to Chatham. They still show the room in the dockyard where the elder Dickens worked, and where his son often came to visit him. The family lived in Ordnance Place, Chatham, and the boy was sent to a school kept in Gibraltar Place, New Road, by one William Giles. As a child he is said to have been a great reader, and very early began to attempt original writing. In 1821, Charles being then nine years of age, the family fell into trouble; reforms in the Admiralty deprived the father of his post and the greater part of his income. They had to leave Chatham and removed to London, where a mean house in a shabby street of Camden Town received them. But not for long. The unfortunate father was presently arrested for debt and consigned to the Marshalsea, and Charles, then only ten years of age, and small for his age, was placed in a blacking-factory at Hungerford Market, where all he could do was to put the labels on the blacking-bottles, with half a dozen rough and rude boys. The degradation and misery of this occupation sunk deep into the boy's soul. He could never bear to speak of this time; it was never mentioned in his presence. Not only were his days passed in this wretched work, but the child was left entirely to himself at night, when he made his way home from Hungerford Market to Camden Town, a distance of four miles, to his lonely bedroom. On Sundays he visited his father in the prison. Of course such a neglected way of living could not continue. They presently found a lodging for him in Lant Street, close to the Marshalsea, where at least he was near his parents, and his father shortly afterwards recovering his liberty, they all went back to Camden Town, and the boy was sent to school again. It was to a private school in the Hampstead Road, where he remained for three or four years of quiet work. It must have been then, one suspects, rather than at Chatham, that he became so great a devourer of books. But he was never a scholar in any sense, and the books that he read were novels and plays. That the family fortunes were still low is proved by the fact that when he was taken from school no better place could be found for him than a stool at the desk of a solicitor. Meantime his father had obtained a post as reporter for the *Morning Herald*, and Charles, feeling small love for the hopeless drudgery of a lawyer's office, resolved also to attempt

the profession of journalist. He taught himself shorthand with the resolution—even the rage—which he always threw into everything he undertook; and he frequented the British Museum daily in order to supplement some of the shortcomings of his reading. In his seventeenth year he became a reporter at Doctors' Commons. At this period all his ambitions were for the stage. He would be an actor. All his life, indeed, he loved acting and the theatre above all things. As an actor one feels certain that he would have succeeded. He would have made an excellent comedian. Fortunately, he was saved for better work.

It was not until he was two-and-twenty that he succeeded in getting permanent employment on the staff of a London paper as a reporter. In this capacity he was sent about the country to do work which is now mainly supplied by local reporters. It must be remembered that there were as yet no railways. He had to travel by stagecoach, by post, by any means that offered. 'I have been upset,' he said years afterwards, speaking of this time, 'in almost every description of vehicle used in this country.'

About this time he began the real work of his life. In December 1833 the *Monthly Magazine* published his first original paper, called 'A Dinner at Poplar Walk.' Other papers followed, but produced nothing for the contributor except the gratification of seeing them in print, because the magazine could not afford to pay for anything. However, they did the writer the best service possible, in enabling him to prove his power, and he presently made an arrangement with the editor of the *Evening Chronicle* to contribute papers and sketches regularly, continuing to act as reporter for the *Morning Chronicle*, and getting his salary increased from five guineas to seven guineas a week. To be making an income of nearly four hundred pounds a year at the age of two or three and twenty, would be considered fortunate in any line of life. Sixty years ago such an income represented a much more solid success than would now be the case. The sketches were collected and published in the beginning of the year 1836, the author receiving a hundred and fifty pounds for the copyright. He afterwards bought it back for eleven times that amount. In the last week of March in the same year appeared the first number of the *Pickwick Papers*; three days afterwards Dickens married the daughter of his friend George Hogarth, editor of the *Evening Chronicle*; and his early struggles were finished.

No article, however short, treating of Charles Dickens, can avoid entering into the details of his early history with a fullness which would be out of all proportion to what follows, but for the remarkable fact that the events of his childhood and his youth impressed his imagination and influenced the whole of his literary career so profoundly, that to the very end of his life there is not a single work in which some of the characters, some of the places, are not derived from his early recollections. Many other writers there are who have passed their childish days among the *petites gens*, but none who have so remembered their ways, their speech, and their modes of thought. The Marshalsea prison of *Little Dorrit* is the place where for two years he went in and out. The Queen's Bench and its Rules were close to the Marshalsea; Bob Sawyer's lodgings in Lant Street were his own; David Copperfield, the friendless lad in the dingy warehouse, was himself; the cathedral of Edwin Drood was that in whose shadow he had lived; Mrs Pipchin is his old landlady of Camden Town; the most delightful features in Mr Micawber are borrowed from his own father; the experiences of Doctors' Commons, the solicitors' clerks, the

life in chambers, are all his own; while of individual characters the list of those which are known to be portraits more or less true to nature might be indefinitely extended. And yet, while he was always drawing on these early recollections, while they constantly furnished him with scenes and characters, he could not bear to speak of them, and no one except his friend and biographer, Forster, ever knew that he was, himself, with all the shabby, mean surroundings in early life, exactly such as David Copperfield.

The rest of Dickens's life has the interest which belongs to success after success. It was a long triumphal march. He had no failures; he suffered no defeats. There were times when his hand was not at its best, but never a time when his hand lost its power. This indeed seems the crowning happiness of a successful and singularly happy life, that when he was cut off—he died June 6, 1870—after fifty-eight years of continuous work, his brain was still as vigorous, his eye as keen, his hand as sure as in the first fresh running of his youth. It was indeed more than literary success which he achieved; he conquered the whole English-speaking world. This world, which now numbers nigh upon a hundred millions, loves him; all who can read his books love him, and shall continue to love him. This love cheered him in his life, and will keep his memory green. Of the solid wealth which he acquired, the honour he enjoyed, the friends who gathered round him, and the brave and resolute front which he always showed, there is no space here to speak.

The following is the list of Dickens's works in their order of appearance, omitting certain farces and pamphlets which belong to a more extended notice: *Sketches by Boz* (1836), *The Posthumous Papers of the Pickwick Club* (1837), *Oliver Twist* (1838), *Nicholas Nickleby* (1839), *The Old Curiosity Shop* (1840-41), *Barnaby Rudge* (1841), *American Notes* (1842), *Martin Chuzzlewit* (1843), *The Christmas Tales*—viz. *The Christmas Carol*, *The Chimes*, *The Cricket on the Hearth*, *The Battle of Life*, *The Haunted Man*, and *The Ghost's Bargain* (1843, 1846, and 1848); *Pictures from Italy* (1845), *Dombey and Son* (1846-48), *David Copperfield* (1849-50), *Bleak House* (1852-53), *The Child's History of England* (1854), *Hard Times* (1854), *Little Dorrit* (1855-57), *A Tale of Two Cities* (1859), *The Uncommercial Traveller* (1861), the Christmas numbers in *Household Words* and *All the Year Round*, *Great Expectations* (1860-61), *Our Mutual Friend* (1864-65), *The Mystery of Edwin Drood* (unfinished). This long roll by no means represents the whole work of this most active of mankind. Public readings both in this country and in America, private theatricals, speeches, letters innumerable, journeys many, pamphlets, plays, the conduct of a popular magazine—first called *Household Words* and then *All the Year Round*—and an ever-present readiness to enjoy the society of his friends, fill up the space when he was not actually writing. That he could do so much was mainly due to his orderly and methodical habits, to his clearness of mind, and to a capacity for business as wonderful as his genius for fiction. He knew no rest from the day when he first attacked shorthand to the day when he fell from his chair in the fit from which he never recovered. He was incomparably the most active man; the hardest-working man of his age. In the history of letters there are many who have produced more work in bulk; there is not one who led a life so varied, so full, so constantly busy, so active and so rich.

It is as yet too early to speak with certainty as to the lasting popularity of his work as a whole. Very much of it owed its general success to the faithful delineation of manners already passed away.

He was the prophet of the middle class, and the manners of that great section of the community have greatly changed since the days when Charles Dickens lived among them and observed them. With the decay of these manners some part of present popularity must certainly pass out of his work: already a generation has appeared to whom a great deal of Dickens's work proves of no interest, because it portrays manners with which they are not familiar. They do not laugh with those who laughed fifty, forty, twenty years ago, because the people depicted have vanished. But when the second quarter of this century shall belong so truly to the past, that not one survives who can remember it, then these books will become a precious storehouse for the study and the recovery of part, and that a large part, of its life and manners.

Again, it is the essential quality of genius to create the type. In this Dickens has been more successful than any other novelist, ancient or modern. With him every leading character stands for his class. Squeers is the representative of the schoolmaster, then too common, ignorant, brutal, and grasping; Winkle is the Cockney sportsman; it is impossible to think of red tape without naming Mr Tite Barnacle; and so on through all the books. If he sometimes too plainly labels his characters with their qualities and defects, it is a fault caused by his own clearness of conception and of execution. It is another note of genius to suffer every character to work out its own fate without weakness or pity, and though Dickens deals seldom with the greater tragedies of the world in his domestic dramas, necessity pursues his characters as grimly and certainly as in real life. The villain Quilp and his tool make us forget, in the amusement which they cause, their own baseness. But their creator is not deceived. He makes them bring their own ruin upon their heads. To be true, not only to the outward presentment and speech and thought of a character, but also to the laws which surround him, and to the consequences of his actions, is a rare thing indeed with those who practise the art of fiction. Further, in this art there are permissible certain exaggerations, as upon the stage. There is exaggeration of feature, exaggeration of talk, exaggeration of action. There are degrees of exaggeration, by which one passes through tragedy, comedy, farce, and burlesque; but in all there must be exaggeration. Dickens was master of exaggeration—if he sometimes carried it too far, he produced farce, but never burlesque. As for selection, which is perhaps the most important point after exaggeration, it came to him by instinct; he knew from the very outset how to select. It is by selection that the novelist maintains the interest of his story and develops his characters. There are countless things that are said and done in the progress of the history which have little interest and small bearing on the things which have to be told; and it is the first mark of the bad novelist that he does not know how to suppress irrelevant scenes. In the constructive branch of his art Dickens continually advanced. His earlier stories seem, like the *Pickwick Papers*, to be made up of scenes. *Nicholas Nickleby* is a long series of scenes brilliantly drawn, in which new characters are always appearing and playing their disconnected part and disappearing. But as he grew older his conception of the story itself grew clearer, and his arrangement more artistic. It is however in description that Dickens proved himself so great a master. He laid his hand by instinct upon the salient and characteristic features, and he never failed in finding the right—the only—words fit for their illustration. In description he is never conventional, always real, and yet he allows himself, here as in his scenes of character and dialogue, a certain

exaggeration which produces the happiest effects. In the hands of his imitators it becomes grotesque and intolerable.

As to his great and splendid gallery of portraits it is difficult to speak briefly. The whole of London life—the life of the streets, of the city, of the middle class—seems at first sight depicted in this gallery. Here are merchant, shopkeeper, and clerk, lawyer and client, moneylender and victim, dress-maker, actor—one knows not what. Yet there are great omissions. The scholar, the divine, the statesman, the country gentleman are absent, partly because Dickens had no knowledge of them, and partly because he forebore to hold them up to the ridicule which he loved to pour over his characters. His methods imposed upon him certain limitations; he aimed at commanding his readers' attention by compelling laughter and tears, but especially laughter. He who can command neither the one nor the other is no true artist in fiction. But in his laughter and in his tears one feels always the kindly heart as well as the skilful hand. It is for the former—for the deeply human heart—even more than for the latter that the world will continue to love the memory of Charles Dickens.

See his *Letters*, edited by his eldest daughter (3 vols. 1879-80); his *Life*, by John Forster (3 vols. 1871-74); the *little Life*, by F. Marzials (1887), with an admirable bibliography by J. P. Anderson; and *Charles Dickens in Pen and Pencil*, by F. G. Kitton (1889).

Diclinous, a term applied by Linnaeus to flowers possessing stamens or pistils only, and opposed to hermaphrodite. Hence the *Diclinia* of the artificial system included *Monacia*, *Diacia*, and *Polygamia*. See FLOWER, REPRODUCTION, SEX.

Dicotyledons. The fact that the majority of young seedlings exhibit two small seed-leaves or cotyledons on germination must have been familiar from time immemorial, while the classificatory importance of this character in broadly separating the obviously flowering plants into two great groups of dicotyledons and monocotyledons was thus naturally one of the earliest conceptions of systematic botany, having been adopted by Linnaeus from Ray, and doubtless by him in turn from earlier writers. We now distinguish phanerogams into Gymnosperms (cycads, conifers, and gnetums), and Angiosperms characterised by the possession of a closed ovary: of these the monocotyledons and dicotyledons are the main alliances, the latter being on the whole the more evolved. The embryo of dicotyledons possesses, with rare exceptions (usually due to parasitic degeneration—e.g. Dodder, q.v.), two cotyledons facing each other, and more or less embracing the plumule, while the albumen is generally proportionally less in quantity than in monocotyledons, and, in fact, is frequently absorbed altogether; these differences being explained through a more precocious acceleration of development (see OVULE, SEED). The cotyledons usually develop equally, but one may be more or less completely arrested.

The fibro-vascular bundles of dicotyledons are open and collateral, with few exceptions arranged in a reticulated cylinder, which thus presents a single circle in transverse section. The parenchyma in which they lie is thus divided into two main regions—the cortical layer or cellular envelope, and the pith; while the intermediate spokes of parenchymatous tissue connecting the pith and cortex through the meshes of the cylinder are the medullary rays. While the fibro-vascular bundles of dicotyledons arise like those of cryptogams and monocotyledons, by the differentiation into wood and bast of a special strand of primitive embryonic tissue continuous with that of the growing point, they differ in a marked

tendency to embryonic persistence of a central layer of this as the Cambium (q.v.), and hence in so many groups of dicotyledons there arises that association of perennial habit and continuous growth of stem to which we owe our familiar shrubs and trees. See HISTOLOGY (VEGETABLE), WOOD, BARK, BAST. Since the cambium lies between the wood and bast, the new layers of wood are external to the older ones, but those of bast internal to their predecessors: hence Lindley's name *exogens* was apt to be misleading. The softness and delicacy of the cambium layer leads, when force is applied, to the easy separation of the bast elements of the fibro-vascular bundles, along with the cortical parenchyma and epidermic layer, as the *bark*—a structure, or rather juxtaposition of structures, unknown in Monocotyledons (q.v.).

The reticulated character of the bundles of the stem is similarly present in the leaf, which thus presents a marked contrast to the usually parallel venation of the monocotyledons. The leaf also presents far greater variety of form and adaptation (see LEAF).

The flower has most frequently its parts arranged in whorls of five, although four is also a not uncommon number; hence another very obvious distinction from monocotyledons, in which a 3-merous symmetry prevails. The outer perianth whorl is most frequently green, as a calyx. See FLOWER, PHANEROGAMS, and VEGETABLE KINGDOM; also ANGIOSPERMS, and MONOCOTYLEDONS.

Dicranum, a genus of mosses, of which some are among the commoner British forms. See MOSSES.

Dictamnus. See DITTANY.

Dictator, in the earliest times, was the name of the highest magistrate of the Latin Confederation, and in some of the Latin towns the title was continued long after these towns were subjected to the dominion of Rome. In the Roman Republic the dictator was an extraordinary magistrate, irresponsible and endowed with absolute authority, whose original name was *magister populi*. The frequency of crises, or critical periods, in the quick, aggressive growth of the Roman state, necessitated such an office. The first dictator (T. Larcus or M. Valerius) was appointed 501 B.C., nine years after the expulsion of the Tarquins. According to Livy, the immediate cause of this dictatorship was a formidable war with the Latins. In general, no one could be appointed dictator who had not been previously consul, and this condition was very rarely dispensed with. Niebuhr is of opinion that the dictator was originally created or elected by the curia, like the kings, but it is more probable that the senate passed a decree ordering one of the consuls to name or proclaim (*dicere*) a dictator. Originally, of course, the dictator was a patrician; the first plebeian who filled the office being C. Marcus Rutilus, 356 B.C., who was nominated by the plebeian consul M. Popillius Lænas. The dictatorship could not *lawfully* be held longer than six months, nor was it ever so, except in the cases of Sulla and Caesar, which were altogether peculiar. It must not be supposed that during a dictatorship the functions of the other magistrates were positively suspended. The consuls and other regular authorities continued to discharge their proper duties, but in subordination to the dictator; being for the time simply his officers. The superiority of his power, when compared with that of the consuls, appears chiefly in these three points: he was far more independent of the senate; he had a more extensive power of punishment, without any appeal; and he could not be called to account after his abdication of the dictatorship for anything he had done during the period of his office. The

limits of his power were as follows: he could not touch the treasury; he could not leave Italy; and he could not ride through Rome on horseback without previously obtaining the permission of the people. While the consuls had only twelve lictors, the dictator was preceded by twenty-four, bearing the *secures* and *fusces*. To him also belonged the *sella curulis* and the *toga praetexta*. The last legally elected dictator was M. Junius Pera, who entered on his office 216 B.C. From this time *nominal* dictators were frequently appointed for the purpose of holding the elections, but even these finally disappeared, 202 B.C.

Dictionary (late Lat. *dictionary*), a book containing the words of a language alphabetically arranged, with their definitions and significations set forth more or less fully. In this respect it differs from a mere list or index, that it contains explanations about each word included within its scope, except where it is more convenient, by a cross-reference, to refer the reader for a part or the whole of the account of one word to what is said under some other word. There are several other terms that are used synonymously, or nearly so, with dictionary. The Greek word *Lexicon* is in common use for a dictionary of languages. It is not entirely so limited, however, in practice, as may be seen in such works as the *Lexicon Juridicum* of Calvinus or Kahl, which is just a dictionary of Roman and feudal law of the same kind as Sir Edward Tomlin's *Law Dictionary* is of English law. The word *Encyclopædia* has generally a wider meaning; but in actual use we find books of reference of exactly the same kind styled indifferently dictionaries and encyclopædias. The terms *Glossary* and *Vocabulary* are nearly synonymous with a dictionary of a language; and *Thesaurus*, *Catalogue*, *Directory*, *Gazetteer*, and *Index* are sometimes used as titles where dictionary might be not inapplicable.

Dictionaries may be divided into two classes—(1) those whose object is to explain words and phrases; and (2) those that aim at giving information about things.

(1) Dictionaries of language are, again, divided into various sub-classes or species. The most common kind—what, indeed, is understood by the term dictionary (and the equivalent Greek term *Lexicon*) when used by itself—is an alphabetical list of the words composing any language either explained in the same language, or interpreted by the corresponding words of one or more other languages. To indicate that all the words of the language are included, the name *Thesaurus* ('Treasury') is sometimes used, as in the great Hebrew dictionary of Gesenius. The words used by particular authors or classes of authors are often explained in *special* dictionaries or lexicons, such as those to Livy, Cicero, Tacitus, Homer, Sophocles, Shakespeare, and the like. A *Glossary* is a dictionary of unusual terms, as archaic, provincial, or technical terms. An *etymological* dictionary is one in which the derivation of words is the sole or a prominent object.

(2) Dictionaries of things (Ger. *Realwörterbücher*), or of information, are also of various kinds. When the whole field of human knowledge is embraced, we have an alphabetical Encyclopædia or Conversations-Lexicon. The name Encyclopædia or Cyclopædia is sometimes given to dictionaries of special departments of knowledge, as *Anatomy and Physiology*; but in all such cases dictionary seems the correcter term, as in the well-known dictionaries associated with the name of Dr Smith, which cover the whole ground of Bible terms, Greek and Roman biography and mythology and antiquities, Christian antiquities, and Christian biography.

There is no kind of information, within wide or

narrow bounds, that may not be thrown into the dictionary form. Dictionaries of apt quotations from the classics, the Scriptures, or the fathers were not unknown in the 17th century. There are dictionaries of biography, of geography, of nautical terms, of dates, of architecture, of cookery, of political economy, of heraldry, of fortification—in fact, of every object of human knowledge and practice.

Dictionaries of language, in our sense of the word, are of modern origin. The Greeks and Romans had no idea of a book embracing all the words of their own or any foreign tongue. Glossaries, however, of unusual words and phrases were early current. The earliest work of the kind extant (though much interpolated) is the Homeric Lexicon (Gr. *Lexis Homerikai*) of Apollonius, an Alexandrine grammarian of the time of Augustus. More extensive compilations, such as the Lexicon of Suidas (q.v.), and the *Etymologicum Magnum* (q.v.), were made in the middle ages. A real dictionary became first possible after the invention of printing. A broad and sure basis for Greek lexicography was laid by Henry Stephens (q.v.) in his *Thesaurus* (1572), on which the school of Hemsterhuis built further, and which has been greatly extended by the labours of Schneider, Passow, Seiler, Jakobitz, Rost, and Pape. The well-known work of Liddell and Scott (7th ed. 1883) is based on the great German one of Passow. The *Thesaurus* (1531) of Robert Stephens inaugurated Latin lexicography, which has been extended by Joh. Matth. Gesner, Forcellini, Ducango (medieval Latin), Scheller, Freund, Georges, Mühlmann, and Vaníček, and is well represented in English by Riddell and White, Andrews, Smith, and the Americans Lewis and Short. The earliest standard dictionaries of modern tongues were the Italian *Vocabulario della Crusca* (1612); the Dictionary of the French Academy (1694); and that of the Academy at Madrid (1726-39). Among recent standard dictionaries, the most important are the great German Dictionary, begun in 1854 by the brothers Grimm, and still unfinished; Littre's French Dictionary (4 vols. and supplement, 1863-78); and the *New English Dictionary* of the Philological Society, which was begun in 1857, and the first volume (A—B) of which appeared, under the editorship of Dr Murray, in 1884-88. The last great work follows a strictly historical method, and aims at giving a complete account of every signification of every word which has ever been printed in English. English-dictionary-making in its larger sense began with Dr Johnson's work, which, with all the defects of its time, remains a monument of industry controlled by genius. The best complete English dictionaries at present in use are Richardson's, Worcester's, Webster's, Latham's edition of Johnson's Dictionary, and Annandale's edition of Ogilvie's Imperial Dictionary; for etymology, those of Wedgwood, Edw. Müller (German), and Professor Skeat. For older English words, the chief are Ælfric's Glossary (about 975), Way's edition (1843-65) of the *Promptorium Parvulorum* (about 1440), Bosworth's *Anglo-Saxon Dictionary*, Strathmann's *Dictionary of the Old English Language*, Grein's *Sprachschutz der Angelsächsischen Dichter*, and Mätzner's *Alt-englische Sprachproben, nebst einem Wörterbuche*.—See BIOGRAPHY, ENCYCLOPEDIA, DIALECT, ENGLISH, and the articles on the various languages; also Vater, *Litteratur der Grammatiken, Lexika, und Wörter-sammlungen aller Sprachen der Erde* (2d ed., by Jülg, Berlin, 1847).

Dictyogens, in Botany, a class established by Lindley for the reception of monocotyledons with reticulated leaves, but no longer accepted. See MONOCOTYLEDONS, LILIACEÆ.

Dictys of Crete, a follower of Idomeneus in the Trojan war, whose name is attached to a professed journal of the leading events of the contest, which has come down to us in Latin prose, under the title *Ephemeris Belli Trojani*. An introduction relates how the narrative, inscribed in Phœnician characters on bark-paper, was found in a coffer of tin in Dictys's tomb, which had been burst open by an earthquake in the reign of Nero, and how the emperor caused it to be translated into Greek; this is accompanied by a letter from one Quintus Septimius, who claims to have prepared the condensed Latin version that follows. This dates probably from the 4th century A.D., and though of no intrinsic value, was a chief source of the romances of the middle ages. The best editions are those of Dederich (Bonn, 1832 and 1837) and Meister (Leip. 1872). See Dunger, *Dictys-Septimius: über die ursprüngliche Abfassung u. die Quellen der Ephemeris* (Dresd. 1878).

Dicymidae, a family of very lowly multicellular organisms, parasitic in habit. They are found in cuttle-fishes, while related organisms known as Orthonectida occur in a brittle-star and in a Nemertean worm. Professor E. van Beneden has included them all under the title Mesozoa in contrast to the lower (single-celled) Protozoa on the one hand, and the higher (many-celled) Metazoa on the other. The largest species of the genus *Dicyma* measures 5-7 millimetres; the smallest is ten times less. These organisms hardly rise above the level of the embryonic gastrula, and some seem hardly to attain it, but it is still uncertain how much of this simplicity is primitive, and how much the result of degeneration. See E. van Beneden and C. Julin, *Archives de Biologie* (1882); Whitman, *Mitth. Zool. Stth. Neapel* (1883); Braun, *Centralblatt Bacteriol.* (1887).

Dicynodon, an important type of Triassic reptile, usually included in the order Anomodontia. They have been unearthed in Africa, India, and the Ural region, and more recently remains have been found in the Elgin Trias of Scotland. Our knowledge of them is largely due to Owen. They were terrestrial animals, and in some ways suggest affinities with tortoises, in others with mammals. In *Dicynodon* the lower jaw was incased in a horny beak, but the upper bore two huge teeth. In *Oudenodon* no teeth were present. See CHELONIA, REPTILE.

Didache. See APOSTLES (TEACHING OF THE TWELVE).

Didactic Poetry, that kind of poetry which aims, or seems to aim, at instruction as its object, making pleasure entirely subservient thereto. It has been disputed whether or not the existence of a kind of poetry especially entitled to the name didactic is consistent with the very nature and object of the poetic art. For it is held that, to point out instruction as the peculiar object of one kind of poetry, is to overlook the high aim of all poetry; and that a poem may be in the highest sense didactic, which yet is epic, dramatic, or lyric in its form; and the Book of Job, the Psalms, and other poems contained in the Sacred Scriptures, are quoted as examples. In the poems generally called didactic, the information or instruction given in verse is accompanied with poetic reflections, illustrations, and episodes. The *Georgics* of Virgil has been the model for most didactic poems, and no subject is so unpromising that it has not found some one to select it as a poetic theme. Examples of admirable success as combinations of argument and poetry are the *Ars Poetica* of Horace and the *Essay on Criticism* of Pope. The great poem of Lucretius, again, stands the masterpiece of the philosophical poem, which is represented in our

own language by poems like the *Noœce Teispaum* of Sir John Davies, and the *Essay on Man* of Pope. See POETRY.

Didelphis. See OPOSSUM.

Diderot, DENIS, was born on October 15, 1713, at Langres, in Champagne, where his family had for two centuries been engaged in the manufacture of cutlery. An eldest son, he was intended for the church, and received his early training at the Jesuit school in his birthplace. After studying at the Collège d'Harcourt in Paris, he offended his father by refusing to become either a lawyer or a physician, and was in consequence flung upon his own resources. From 1734 until about 1744 he led a life of haphazard, ill-paid toil as a tutor and a bookseller's hack. In 1744 he married Annette Champion, a young sempstress, against the wishes of her friends, and without the knowledge of his family. After she had borne him a son, he persuaded his wife to remove with the child to Langres, where she brought about a reconciliation between Diderot and his father. His marriage, however, did not prove a happy one. During his wife's absence in Champagne he formed a liaison with a Madame Puisieux which lasted for several years; and later in life he became attached to a financier's daughter, Mademoiselle Voland, to whom he remained devoted until her death in 1774. His *Pensées Philosophiques* were burned by order of the Parliament of Paris in 1746, and three years afterwards he underwent imprisonment for the opinions expressed in his *Lettre sur les Aveugles*. His appointment to the editorship of an encyclopædia which the bookseller, Le Breton, had resolved upon publishing, assured him of a regular income, and gave him a commanding position in the world of letters. Le Breton's intention had been merely to issue an expanded version of the *English Cyclopædia* of Ephraim Chambers, which had appeared in 1727. But in Diderot's hands the character of the work was transformed. He enlisted nearly all the important French writers of the time as contributors, and in place of a storehouse of useful information, produced an engine of war for the *philosophe* party (see ENCYCLOPÆDIA). For some twenty years he stood at his post in spite of dangers and drawbacks, before which even a strong man might pardonably have flinched. The book was again and again threatened with prosecution; its sale was more than once prohibited; its editor ran a constant risk of imprisonment or exile. D'Alembert, at one time co-editor with Diderot, forsook him in despair at the obstacles to be overcome. But his marvellous energy, his varied knowledge, above all, his faculty of rallying and inspiring his fellow-workers, enabled Diderot to carry his vast undertaking to a successful conclusion. The first volume appeared in 1751; the last, in 1765. In his later years Diderot fell into pecuniary difficulties from which he was rescued by Catharine II. of Russia, who purchased his library, but allowed it to remain in Paris, and installed him at a salary as its caretaker. In 1773 he paid a visit to his benefactress, by whom he was most cordially received. He returned to Paris after spending five months in the palace of the empress at St Petersburg, and four months at the Hague as the guest of Prince Galitzin. During his old age he lived principally in his study at the corner of the Rue Taranne, spending his days in reading and meditation, in directing the studies of his daughter—the only survivor of his four children, in the giving of good counsel, and the doing of good works. He died from a stroke of apoplexy on the 30th July 1784.

One of the most prolific and versatile, Diderot was also one of the most careless of writers. He

worked in almost every department of literature. He was a novelist and a dramatist, a satirist, a philosopher, a critic of pictures and books; while as a letter-writer he was surpassed by none of his contemporaries. His published works are far from embodying the results of his labours as an author. He was ever ready to contribute without reward, often without acknowledgment, to the writings of others; he has been well termed the munificent prodigal of letters. His efforts in fiction include a story in the manner of Crébillon, described by Carlyle as 'the beastliest of all past, present, or future dull novels'; *La Religieuse*, a powerful story written with the object of exposing the evils of conventual life; and *Jacques le Fataliste*, a collection of short tales of which some are good and others indifferent, while one of them is a little masterpiece. *Le Neveu de Rameau*, an imaginary conversation between the author and a parasite of the great, is probably the strongest as it is the most curious of all Diderot's works. In the course of this dialogue, which was translated by Goethe, the follies and corruptions of society are laid bare with sardonic humour and piercing insight. Diderot's plays were somewhat unsuccessful examples of what was then known as *tragédie bourgeoise*, or of what we should now term melodrama. His happiest dramatic efforts were two short pieces which were never acted, *La Pièce et la Prologue* and *Est-il Bon? Est-il Méchant?* The letters which he addressed to Madoiselle Volland, and which were first published some fifty years after his death, form the most interesting section of his voluminous correspondence. They give an entertaining and wonderfully vivid picture of the life that was led in the Baron d'Holbach's country-house at Grandval, the headquarters of the most advanced members of the *philosophes* party. As a critic Diderot stood far in advance of his contemporaries, and anticipated the Romanticists in advocating a return to nature and in seeking to free the drama from the trammels which had been imposed on it by the classical school. His criticisms bear the marks of over-hasty production, but their originality, shrewdness, and abounding vivacity more than atone for the lack of literary finish. His *Salons*, remarks on pictures exhibited at different times in Paris, are the earliest example of aesthetic criticism in modern literature. His philosophical works include *Pensées Philosophiques*, *La Promenade du Sceptique*, *Lettres sur les Sourds et Muets*, *Lettre sur les Aveugles*, *La Révocation d'Alambert*, *Essai sur la Vie de Sénèque*, *L'Interprétation de la Nature*, and a long criticism on Helvétius's treatise *De l'Homme*. Diderot has been frequently described as an atheist; whether justly or not is a matter very hard to decide. He was at one time deeply influenced by the naturalistic religion of Shaftesbury, and that writer's influence upon his mind was never wholly effaced. In certain passages he appears to write as a pantheist. But he never set forth his philosophy in consistent and systematic form.

Diderot is so unequal a writer that his works must be read in the mass before a just estimate can be formed of his extraordinary gifts. His keenest sayings, his most pregnant thoughts, are frequently imbedded in dullness. An indefatigable worker, he yet never took his work seriously enough. He lacked the faculty of concentration and the artist's mastering sense of form. His prose is not sustained at a high level of excellence; he sins grievously against good taste; his thoughts are not seldom crude and shallow; his mannerisms—notably his abuse of apostrophe—his 'sensitivity' and his *philosophie* cant are not a little trying to the reader. But with all their defects his writings are wonderfully alive—fertile in original ideas—racy with a stimu-

lating flavour which is all their own; abounding in careless felicities of phrase and in sayings which flash a new light into human nature; rich with the sap of a humour which resembles the humour of no other Frenchman, and which Carlyle has likened to the humour of Cervantes. Inferior to Voltaire and Rousseau as a literary craftsman, he was a deeper thinker than either; his knowledge of men was profound, and his learning was truly encyclopædic. Ardent and generous, though lacking in self-restraint, he was one of the best of friends and the most charming of companions. In the opinion of his contemporaries his powers as a conversationalist eclipsed his gifts as a writer. He appears to have possessed an unrivalled faculty of improvisation; to judge from the testimony of shrewd critics who listened to him, his talk was as pointed and pregnant in its substance as captivating in its eloquence. 'He who knows Diderot only in his writings,' said Marmontel, 'does not know him at all.'

The most complete edition of his works is that by Assolzat and Tournier (20 vols. 1875-77). See the exhaustive study by Rosenkranz (2 vols. Leip. 1866); John Morley's *Diderot and the Encyclopædists* (2 vols. 1878); E. Scherer's study (1880); Sainte-Beuve's *Portraits Littéraires*, vol. I.; and Carlyle's article on Diderot in his *Miscellanies*.

Dido, or ELISSA, the legendary founder of Carthage, was the daughter of the Tyrian king Belus or Agenor, and the sister of his successor, Pygmalion. Pygmalion murdered her husband and uncle, Acerbas or Sichæus, a priest of Hercules. With the treasures of Sichæus, which Pygmalion had sought for in vain, and accompanied by many Tyrians, Dido escaped to sea. She landed in Africa, not far from the Phœnician colony of Utica, and built a citadel called Byrsa (Gr. *Bursa*, 'the hide of a bull'), on a piece of ground which she had bought from the Numidian king Iarbas. The meaning of the word Byrsa gave rise to the legend that Dido purchased as much land as could be encompassed with a bullock's hide. Once the agreement was concluded, she cut the hide into small thongs, and thus inclosed a large piece of ground, on which she built the city of Carthage. To avoid being compelled to marry Iarbas, she stabbed herself on a funeral pile, which she had caused to be erected, and after her death was honoured as a deity by her subjects. Virgil ascribes the death of Dido to her unrequited passion for Aeneas; but many of the ancient writers conceived that the poet had committed an anachronism in making her contemporary with the Trojan prince. In the common chronology, more than three hundred years separated the fall of Troy (1184 B.C.) from the founding of Carthage (853).

Didot, the name of a celebrated family of French printers and publishers.—FRANÇOIS DIDOT (1689-1757) was the first of the family that attained eminence. His principal professional achievement was the publication of the *Voyages* of his friend the Abbé Prévost, a work in 20 volumes, perfect as regards the text, and enriched with a great number of engravings. Two of his sons, FRANÇOIS AMBROISE (1730-1804) and PIERRE FRANÇOIS (1732-1795), also acquired distinction as printers, the former publishing editions of the *Delphin* classics, while the latter improved the typesetting and paper-making arts.—HENRI (1765-1852), eldest son of Pierre François, made himself famous as an engraver and letter-founder, producing very beautiful 'microscopic' types.—PIERRE, eldest son of François Ambroise (1760-1853), still further increased the fame of the family. His Louvre editions of Virgil, Horace, Racine, and La Fontaine are magnificent; and he it was who published Boileau's works and Voltaire's *Henriade*.

He was himself an author.—His brother, FIRMIN (1764–1836), as a printer, and especially as an engraver and founder, raised the family name to the pinnacle of professional eminence. The perfect Roman characters, used in the Louvre editions printed by his elder brother, were engraved and cast by him. He revived and developed the stereotyping process, and produced singularly perfect editions of many classical, French, and English works. He became a deputy, and obtained some reputation as an author by his tragedies, *La Reine de Portugal* and *La Mort d'Annibal*, and several volumes of metrical translations from the classics.—Firmin's sons, AMBROISE FIRMIN (1790–1876) and HYACINTHE FIRMIN (1794–1880), long carried on the family business in Paris, aided by their sons, under the firm of Firmin Didot Frères; and in the hands of the present representatives of the family, the business still maintains its magnitude. See the books on the family by Werdet (1864) and Brunel (1871).

Didymium is a very rare metal found in the minerals Cerite, Allanite, &c. Its symbol is Di, its atomic weight 142, and its specific gravity 6.5. It is found associated with Cerium and Lanthanum, and as the salts of the three metals have closely similar properties, their separation is very difficult. The salts of didymium are generally soluble and rose-coloured. The hydrated oxide is a gelatinous precipitate resembling alumina. None of its compounds have anything specially characteristic in their properties except the absorption bands in the spectrum. The metal has an iron-gray colour, with a yellowish tinge. It readily tarnishes in the air, and burns brilliantly when held in a flame.

Diebitsch, JOHN CHARLES, COUNT, a Russian field-marshal, was born in Silesia in 1785, made the campaigns of 1805 and 1812–14. In the Turkish war of 1829 he won the bloody fight in the narrow passes of Kulevtscha; and his difficult passage of the Balkans, preliminary to the advance on Adrianople, was commemorated in the surname conferred on him of Sabalkanski ('crosser of the Balkans'). He died of cholera in February 1831, while endeavouring to suppress the insurrection in Poland.

Diefenbach, LORENZ, a great philologist, was born at Ostheim, in the grand-duchy of Hesse, 29th July 1806, studied theology and philosophy at Giessen, travelled much, and was twelve years pastor and librarian at Solms-Laubach. In 1848 he settled at Frankfort-on-Main, where in 1865 he was appointed second librarian to the city. Here he died, 28th March 1883. His literary industry was enormous, embracing poetry and romances, as well as those more ponderous works by which his name will live. His greatest books—monuments of sagacity and learning—are *Celtica* (3 vols. 1839–40); *Vergleichendes Wörterbuch der Gotischen Sprache* (2 vols. 1846–51); *Glossarium Latino-Germanicum mediæ et infimæ ætatis*, a supplement to Ducange's well-known Glossary (1857); *Origines Europææ*; *Hoch- und Niederdeutsches Wörterbuch* (with Wülcker, 2 vols. 1874–85).

Diefenbach, JOHANN FRIEDRICH, surgeon, was born at Königsberg, 1st February 1794, and in 1832 became extraordinary, in 1840 ordinary, professor of Surgery at Berlin, where he died, 11th November 1847. He was distinguished as an operator, especially in the art of forming by transplantation new noses and lips. He wrote several works of no great importance on surgery, being little more than a brilliant operator.

Diego Garcia, an island of the Indian Ocean, in 7° S. lat., and 72°–73° E. long., extends in an irregular horseshoe shape, and is 30 miles long, embracing between its extremities three minor

islets (the Chagos Islands). It contains a spacious bay, and is very convenient for coaling purposes. The group has about 700 inhabitants, and is a dependency of Mauritius.

Diego Suarez, the name of a fine bay at the north end of Madagascar (q.v.), ceded to France by treaty in 1885.

Diely'tra. See DICENTRA.

Diepenbeck, ABRAHAM VAN, painter and draftsman, was born at Bois-le-Duc in 1607, or, according to other accounts, in 1596. He studied under Rubens in Antwerp, and after a residence in Italy, returned to be an assistant of that painter. He first devoted himself to glass-painting; but he soon turned to oil-painting and designing. Examples of his work in oils are in Paris, Dresden, and Vienna. His plates to Marolles' *Tableaux du Temple des Muses* (1655), engraved by Cornelis Bloemaert, were much admired. He visited England in the reign of Charles I., where he painted some windows, and was much employed by the Duke of Newcastle, for whom he executed various portraits and views, and drew the plates for that nobleman's famous folio on Horsemanship (1637). These plates are valuable not only for their excellence, but for the number of portraits they contain. He was elected president of the Antwerp Academy in 1641, a post which he retained till his death in 1675.

Dieppe, a seaport in the French department of Seine-Inférieure, on the English Channel, 40 miles N. of Rouen by rail. It is situated among chalk cliffs, at the mouth of the river Arques, and is regularly built. It has a castle (1433), now occupied as barracks, commanding the town and the harbour, which admits vessels of 600 tons. Dieppe has a college and a school of navigation, and there is a fine Gothic church of the 13th century, as well as a handsome bathing establishment and casino. Being one of the principal watering-places of France, the town has a great accession of visitors during the summer months. It manufactures clocks, lace, and tobacco; and its carved articles of horn, bone, and ivory have long been famous. There are also shipbuilding yards and distilleries; and the fisheries, which are important, employ almost the whole of the population of Pollet, one of the two suburbs of the town. In 1066 Duke William sailed from Dieppe to the conquest of England. It was then a mere village, but its importance steadily increased, until it reached the heyday of its prosperity in the period between the middle of the 14th century and the end of the 17th. Expeditions sailed hence for the west coast of Africa, where Petit Dieppe was founded at the mouth of the Gambia; and many of the early voyages to Canada were made from this port. A terrible bombardment by the English and Dutch, however, destroyed all but two or three buildings in 1694; and though rebuilt, the town never recovered its importance, and even before the rise of Havre had already sunk to a secondary port. Nevertheless, packets still ply regularly to New-haven. The town is a favourite landing-place of English tourists, and its import and export trade is chiefly with England and Norway. Pop. (1872) 19,757; (1886) 22,599.

Die-sinking, the art of engraving the die or stamp used for striking the impression on coins and medals, and for stamping thin plates of metal into various shapes. The method of sinking the dies used for coins or medals will serve to illustrate the general method of die-sinking. Suppose the coin to be of the size of a shilling: a cylindrical piece of carefully selected steel, about three or four inches in length, and two in diameter, is prepared by slightly rounding one end of the cylinder, then turning and smoothing upon the middle of this a

flat face equal to the size of the coin. This blank die, which is carefully softened by the process of Annealing (q.v.) is then engraved with the device of the coin in intaglio. This is a very delicate and artistic operation, and is effected by a great number of careful touches with small and very hard steel tools. The face of the die is now protected with a thin coating of lampblack and linsed-oil, and then placed with its face downwards in a crucible containing animal charcoal. In this position it is raised to a cherry-red heat, then taken out, and hardened by being plunged into water. When properly tempered, it is in a state to be used for stamping the coin; but dies of superior workmanship, from which many impressions are required, are not thus directly used, as the expense of engraving is very great, and the risk of breakage considerable. This first engraved die, called the matrix, is therefore reserved only for making other dies. An impression in relief is made from this matrix on a small block of soft steel, which is called the puncheon; this is retouched and hardened, and from it the dies directly used for striking the coins or medals are impressed. When the engraving is not very costly, a small number of impressions required, or a soft metal is to be stamped, as in livery buttons, for example, the work is stamped directly from the engraved die or matrix. See MINT.

Die-engraving is a very ancient art, and was perhaps first suggested by the closely allied art of engraving gems. Notwithstanding the great number of ancient Greek coins which have been preserved, it is stated by Mr R. S. Poole, of the British Museum, that only one of the many dies which were used for these has ever been found, or at least only one believed to be of undoubted authenticity. The Greek coins struck between the years 415 and 336 B.C. show that the art of engraving dies had then reached the highest point of excellence which it ever attained either in ancient or modern times. As works of art, the Italian medals of the 15th and 16th centuries come next in merit to Greek coins, but none of these of the 15th, and only the smaller sized ones of the 16th century time were struck from dies. All the others were cast either from wax models or from patterns made in other materials. The art of cutting dies, in the comparatively deep intaglio required for medals, consequently dates from the beginning of the 16th century. Since then, or soon after it, Germany, France, Russia, and England, as well as Italy, have all had many more or less famous die-engravers.

The engraving of dies for medals is perhaps that branch of the art which gives the greatest scope for artistic skill, although the work on those required for coins is nearly identical in its character. Comparatively few dies of new design are, however, required for coins, while many hundreds of medal dies are annually made in England. The medals struck from these are used for such purposes as awards at exhibitions, colleges, and schools; for prizes at various games, and in commemoration of various events. Copper, bronze, and tin are the metals most commonly employed for medals, the copper being usually 'bronzed' on the surface. A copper medal with a head in moderately high relief requires half a dozen blows in the screw-press to bring up a sharp impression; but some in very bold relief require to be struck with as many as thirty blows. The medal requires to be frequently annealed during the process. Coins are finished at one blow, so that the devices upon them are only in slight relief. When a coin or a medal is being struck, a steel collar, accurately fitted to the die, is used to prevent the metal from spreading.

Dies have been extensively applied in Birmingham and other places to the manufacture of many

kinds of objects in sheet-metal. These are of all sizes, from those required for parts of jewelry up to dies weighing more than a ton. Large and heavy dies are, however, cast, and only in some cases finished with the graver—those for such articles as curtain-pole and cornice ornaments being among the largest kinds worked up and finished with the die-cutter's tools. Dies have recently been used in America in the stamping or pressing of solid pieces of wood into lion's heads, rosettes, and other ornaments, in high relief, to imitate wood-carving. By the same process similar ornaments, in bas-relief, are made in pieces of wood formed of several layers of veneers.

Dies Irae, the name generally given to the celebrated Latin hymn on the Last Judgment, from the first words of its first stanza:

Dies Irae, dies illa
Solvat sæculum in favilla,
Teste David cum Sibylla.

This incomparable hymn consists of seventeen such stanzas, with an eighteenth of four lines, and is based on the prophetic passage, Zephaniah, i. 14-18. It is probably the work of the Franciscan, Thomas de Celano, who died about 1255. The sublimity and force of its thoughts are well matched with the impressive solemnity of the verse, its stanzas of three lines, each with the same double rhyme, making the inmost soul tremble, 'as with three blows of a hammer,' says Guericke. It is said to have first appeared in the missals made at Venice about 1250, and is one of the five 'Sequences' that have been universally used in the Roman Catholic Church since the Council of Trent. Its place is in the *Missa in commemoratione omnium fidelium defunctorum*. The Tridentine text, published in 1567, is somewhat different from that in the old missals, and another and considerably inferior version appears on a marble tablet of unknown date, in a Franciscan church at Mantua. The *Dies Irae* has been the subject of musical compositions by Palestrina, Haydn, Cherubini, and Mozart, and no religious poem has been more frequently translated. There are English translations by Craslaw, Macaulay, Lord Lindsay, Isaac Williams, and others. The opening stanzas are paraphrased in the *Lay of the Last Minstrel*, canto vi. See Lisco, *Dies Irae* (Berlin, 1840); treatises on medieval Latin Sequences, by Bartsch (Rostock, 1868) and Kehrein (Mainz, 1873); and 'Fifty Versions of the *Dies Irae*' in the *Dublin Review* (1882).

Diest, a town and fortress of Belgium, in the province of Brabant, on the river Demer, 37 miles SE. of Antwerp by rail, with manufactures of woollen goods, beer, and gin. Pop. 7599.

Diet. The different classes of food-stuffs, and the value or potential of different foods, are described in the article FOOD. In the article DIGESTION the changes which the food undergoes in the alimentary canal are treated. It is here proposed to describe the quantity and quality of food which experience has shown to be required in order to preserve the body in health and vigour. Of course, no two individuals are alike, and the assumption will in the first place be made that an average healthy man of ordinary height and weight, and doing ordinary work, is alone under consideration.

In order to understand the requirements of the body in respect of food, it is necessary to bear in mind how complex the body is. Its chief activities are muscular and nervous, and not only have the brain and the muscular system to be fed, but in addition the various glands, cartilages, bones, and other tissues are all constantly requiring nourishment. If we examine all these tissues under the microscope, we see that although all are alike in some respects, yet that they differ one from another

considerably in others. Their work, too, is different; and we should expect, and experiment shows, that they require different food.

Just as the life of the whole body is the sum of the lives of the different parts (cells) of the body, so the food must contain that which is necessary for these parts. The body has frequently been compared to a steam-engine, but, as we have seen, the body is complex, and the comparison should rather be between it and a collection of steam-engines, each one differing from the other in its pattern, use, and the kind of fuel required to stoke it. A steam-engine requires a store of fuel (containing the potential-power), by the combustion of which it moves. It also requires its parts to be repaired, and sometimes a new boiler or piston is necessary. In addition, it requires other things, so that it may work well, such as oil, which is neither burned nor used to build up the machine. In the same way the body, and each part of it, requires first, a store of fuel, from the combustion of which its energy or activity is obtained; secondly, material by which its wasted parts may be repaired; and, thirdly, substances such as water, salt, &c., which are required by the body, but which are neither burned nor used entirely in forming tissue. The term 'food' may then be applied to all that the body requires from without; and following out our comparison, corresponds with the stoking, mending, and oiling of a number of steam-engines.

Let us consider in the first place the food, which, like the fuel for the engine, the body requires in order to manifest its own peculiar activities. The coal of an engine contains carbon and hydrogen, which become oxidised by the oxygen of the air. As a result of this oxidation, we have heat and mechanical motion. In like manner the body receives food containing large quantities of carbon and hydrogen. At the same time oxygen is absorbed by the blood as it passes through the lungs. The digested food and the oxygen are taken by the blood to the tissues—muscles, brain, &c.—and within these tissues a slow oxidation takes place, giving rise to the heat of the body as well as mechanical and other activities. Just as the steam-engine requires a sufficiency of coal, so the body requires a certain quantity of food. In both cases the supply of oxidisable material must have what may be termed a sufficient 'potential'—that is to say, it must have the power of producing a certain amount of heat and mechanical motion. Some coals and some foods burn better than others, and their potential in that case is greater. Fat among the food-stuffs has the greatest potential, carbohydrates and albumens have less. It is obvious then that one cannot speak of the body requiring a certain weight of food per diem. This would mean nothing, for the value of different food-stuffs varies considerably, a pound of one kind of food being equivalent in potential, say, to twenty pounds of another. In arranging a diet one must carefully consider not only the quantity of food given, but in addition one must calculate its potential. The steam-engine may be driven at full or at half power, and in the latter case the amount of fuel required will be diminished. In the same way an individual doing hard work requires food with more potential, or, as we say, more nutritious food, than another living an easy and uneventful life, and still more than one confined to the house or to his bed.

There is yet another important point to be considered. In a steam-engine the production of heat is not what is sought as a result of the combustion within the steam-engine; the engineer constructs the machine with a view to obtaining the result of the combustion not in heat, but in mechanical motion. In the best machines, one-tenth of the

potential is converted into work, while the rest, nine-tenths, is rejected into the atmosphere as heat. The human mechanism can convert as much as one-fifth of the potential of its food into work, and changes four-fifths into heat. In the case of the human machine, however, heat is very necessary, especially if the body be ill clothed or surrounded by a cold medium. The powerlessness of the hands when numbed with cold will illustrate the necessity of a requisite temperature. Warm clothing actually saves food. Not only is the temperature of the body maintained in a cold climate by preventing its conduction and radiation from the body by the use of warm clothing, but appetite prompts the consumption of a large quantity of food, and especially those kinds that contain great potential. The Eskimos devour great supplies of fat blubber, and they are even said to prefer the taste of rancid oil to that of the less combustible sugar.

It has been found by experiment that a man of average height and weight, well clothed, in a temperate climate, and doing a fair day's work, requires such quantity of food that the combustion of it, were it all converted into mechanical work, would raise 4000 tons one foot high, or, as it is expressed, 4000 foot-tons. This result has been arrived at by varying the diet until the minimum but sufficient quantity has been arrived at which will preserve the health and vigour. The potential of the diet can be calculated by an instrument called the calorimeter, which will give the heat produced during the burning of any combustible substance, and from the heat produced the potential in respect to mechanical work can be calculated. In the subjoined table the potentials of one ounce of each of three important food-stuffs are given:

	Foot-tons.
Fats (beef fat).....	161.56
Proteids (albumen).....	165.2
Carbohydrates (starch).....	161.66

It will at once be seen how readily one could calculate the amount of food-stuff capable of furnishing the body with fuel for twenty-four hours. All that is necessary will be to divide 4000 by the number of foot-tons which correspond with the article selected; the quotient is the number of ounces required. Thus 11 ounces of fat, or 24 ounces of albumen, or 26 ounces of starch would contain the necessary potential.

From what has already been said regarding the complexity of the bodily mechanism, it may be surmised that a single food-stuff (even if a quantity be taken which provides a sufficient potential) is incapable of stoking the body. Numerous experiments, such as those conducted by the Gelatine Commission, by Dr Hammond, and others, indicate that the body is unable to maintain its natural vigour on a diet consisting solely of gelatine, or of starch, of albumen, or of fat, &c. Animals fed on a single food-stuff waste rapidly, and will refuse their food after a few days with marked dislike, dying eventually of starvation. At least two staple articles of food must be given, mixed, even in this case, with many accessories, such as various salts, aromatic substances, &c., in order that health may be maintained.

Liebig taught that the muscular work of the body results from the oxidation of nitrogenous matter (albumen, both animal and vegetable), but it is now known that all the classes of food-stuffs except the mineral matters are used by the muscles. Nevertheless proteids (nitrogenous food) are essential, as we shall see on experimental grounds, and from the fact that in the dietary of every nation, proteid matter is always present, combined at any rate with fat, generally with carbohydrates as well.

In many parts of the world man subsists with-

out the use of carbohydrates. The Eskimo and the North American Indian live entirely on the produce of the chase. The flesh of animals is rich in proteids and fats, but contains practically no carbohydrate. In the same way the Arab of the desert lives upon the flesh and milk of the camel, in districts where the date is not to be found. The use of carbohydrates is extensive in most temperate and tropical climates. Many of the inhabitants of India and Ceylon live chiefly on rice. Wheat, potatoes, and other vegetable foods, rich in carbohydrates, are staple articles of food both in Europe and America. In fact, within certain limits, man, like every other animal, is capable of adapting himself to the food produced by the district in which he lives. The French and Spanish peasants eat little meat, living on carbohydrates and vegetable proteids, and supplying necessary potential by an abundance of oil. The Sussex labourer consumes his beans, rich in vegetable proteids, and bacon, and does a good day's work on them. The Scotch labourer of a former generation lived on porridge and skimmed milk, with meat but once a week. The Arab of the Sahara, together with his family and his horse, subsist almost entirely on the date, while the Arab of the Nubian Desert hardly ever touches vegetable food. The diet of every man, under whatever circumstances, invariably contains proteids, although this may vary in its quantity. The universal use of proteid matter in some form or other suggests its importance, and this is fully borne out by the evidence of direct experiment. If proteid food be withdrawn from the diet altogether, nitrogenous matter continues to be eliminated from the body by the urine, although its supply is cut off. At the same time the body wastes, and death finally occurs. The experiments of Fick, Wislicenus, and Parkes show that during muscular exertion the body does not excrete any excess of nitrogen; and the writer's own researches show that urea—the most important excretion which contains nitrogen—is not found in abnormal extent in muscular tissue after exhaustive exercise. It would appear, therefore, that nitrogenous matter is not used by the tissues for fuel, and that when proteid food is consumed, the muscles burn a non-nitrogenous substance which is formed from it. The nitrogen, in the form of urea, &c., is carried by the blood to the kidneys, and at once excreted. We must look elsewhere than in the ordinary combustion of a muscle or brain cell for a use for the nitrogen which, as we have seen, is so necessary an article of food in the form of a proteid substance. In the child, the tissues which contain nitrogen in definite proportion are continually growing, and it will readily be seen that here, at any rate, we have an important use for proteid diet—namely, to furnish the necessary nitrogen for the new tissue. Even during adult life we have tissue change and growth. The skin is continually growing in its deeper layers to replace its surface layers worn away by constant friction. In the same way the cells of the blood are always being broken down, and their places taken again by new ones continually forming. Although it is hardly probable that such complete changes take place in all the tissues of the body, yet, without the entire breaking down of individual cells, there are no doubt changes both integrating and disintegrating, which are constantly taking place. As a result of disintegrating changes nitrogenous matter in an effete form is being given off by the system, and it has to be replenished from without in a form which the body can use. The proteid food-stuff provides nitrogenous pabulum for the tissues which they assimilate, and build up new tissue material. For this reason proteid matter is indispensable. At the same time the system obtains

from the proteid food non-nitrogenous fuel to be burned by the tissues; this property of supplying tissue fuel is shared with the carbohydrate and fatty food-stuffs. It has been found by experiment that an ordinary diet should contain one part of nitrogenous matter (proteids) to about four of non-nitrogenous diet (fat and carbohydrates). If less nitrogenous matter be given, the tissue consumption of nitrogen will not be supplied, and the body will waste. If a much larger quantity of nitrogenous food be taken, a nitrogenous surfeit occurs, and the body is called upon to digest this excess, and to eliminate an unnecessary quantity of the useless nitrogenous compounds which result.

We have seen then that an ordinary diet must contain sufficient potential, and in addition one part of proteid to four of non-proteid material should be present. The following table from Dr Parkes shows the proper proportions of solid water-free food-stuffs in ounces required as daily food by an adult man:

	At Rest.	Ordinary Work.	Hard Work.
Proteids	2.5	4.6	6 to 7
Fats	1	3	3.5 to 4.5
Carbohydrates	12	14.4	16 to 18
Total water-free food ..	15.5	22.0	25.5 to 29.5

Taking the diet table for a man performing ordinary work, we have 4.6 of proteid, and 17.4, or nearly four times as much non-proteid matter. It contains sufficient potential, for if the number of foot-tons which result from the combustion of an ounce of proteid, of fat, and of a carbohydrate be multiplied by the number of ounces of these substances given in the ordinary diet, it will be seen to amount to 4000. This, as we have already seen, indicates a sufficient potentiality.

It now becomes an easy matter to construct a diet table of articles of food. Most of these have been analysed, and the amount of water, proteid, carbohydrate, or fat in each calculated.

TABLE FOR CALCULATING DIETS (*Parkes*).

Articles of Food.	Water.	Proteids.	Fats.	Carbo- hydrates.	Salts.
Uncooked beef } and mutton ..	75	15	8.4	..	1.6
Fat pork	39	9.8	48.9	..	2.3
Dried bacon	15	8.8	73.3	..	2.9
Smoked ham	27.8	24	36.5	..	10.1
White-fish	78	18.1	2.9	..	1.0
Poultry	74	21	8.8	..	1.2
White bread	40	8	1.5	49.2	1.3
Wheat-flour	15	11	2	70.3	1.7
Barley-meal	11.3	12.7	2	71	3.0
Rye	13.5	13.1	2	69.3	2.1
Biscuits	8	15.6	1.3	73.4	1.7
Rice	10	5	8	88.2	.5
Oatmeal	15	12.6	5.6	63	3
Maize	13.5	10	6.7	64.5	1.4
Macaroni	13.1	9	8	76.8	.8
Arrowroot	15.4	8	..	88.3	.27
Dry peas	15	22	2	53	2.4
Potatoes	74	2	16	21	1
Carrots	85	1.6	25	8.4	1
Cabbage	91	1.8	5	5.8	.7
Butter	6	8.3	88	..	2.7
Eggs	73	13.5	11.6	..	1
Cheese	36.8	33.5	24.3	..	5.4
Milk	80.8	4	3.7	4.8	.7
Cream	66	2.7	20.7	2.8	1.8
Sugar	3	96.5	.5

Many articles of food owe their chief importance to their action as stimulants. Such are alcohol, tea, coffee, and beef-tea. Alcohol is no doubt burned within the body, and is a source of energy. Only a small quantity, however, can be so utilised, perhaps one ounce in every twenty-four hours in the case of an ordinary individual. As a source of energy, therefore, it is of little value, and such substances as fat, meat, bread, are capable of supplying the

potential at a very much smaller cost. Alcohol taken with other food stimulates the secretion of gastric juice, assisting in that way the digestive process. At the same time, however, the gastric juice is unable to act quite so readily upon the food, though this is hardly the case with diluted spirits, which form more wholesome beverages than wines or beer. No two individuals are the same, and while alcohol, in moderate doses, promotes digestion in most persons, others suffer from its use. (See the article on the action of alcohol, Vol. I. p. 135). It should never be given in collapse and weakness without giving at the same time easily digested food when that is possible. It excites the body to great and often unnecessary activity, the potential for which it does not supply. Afterwards greater weakness ensues from want of the necessary fuel, which has not in the meanwhile been forthcoming. One should never drink without eating. Tea and coffee are both nervous stimulants, and at the same time they retard both gastric and salivary digestion.

Beef-tea is generally regarded as a food-stuff of high nutritive value. This is, however, not the case. It contains nothing besides salts and extractives, and has a very slight potential indeed. It has a stimulating effect, however, both on digestion and on the nervous system. From the mistaken ideas generally held as to the nutritive properties of this substance, thousands of invalids are annually starved to death (see BEEF-TEA). Beef-tea made by infusing the beef in *tepid* water is more nutritious, especially if the beef be finely minced and eaten as well.

In addition to the stimulants that we have already considered are many substances known as condiments, such as mustard, pepper, pickles, sauces. These are of utility in gratifying the palate, and in addition they probably stimulate the secretory juices. Sufficient information has not as yet been obtained as to their action on gastric and pancreatic digestion. They certainly stimulate the flow of saliva, although the acid condiments will prevent the perfect action of the salivary ferment.

Common salt is a condiment, and at the same time it plays many other important parts in the animal organism. So necessary is it that both man and animals suffer great hardships if it be not supplied in sufficient quantity. It is necessary for the formation of the gastric juice; it is present in the blood and in all tissues of the body.

Inorganic salts, such as sulphates, phosphates, are required for the formation of the skeleton, and salts of iron for the colouring matter of the blood. Organic salts, such as citrates and tartrates, are also of importance. That food should be easily digested is a matter of great importance. The rapidity of digestion will depend upon the amount and quality of the digestive juices, the kind of food, and the condition in which the food is eaten. Rice, tripe, whipped eggs, sago, tapioca, barley, milk, raw eggs, lamb, parsnips, potatoes, hashes of chicken, fish, are all easily digested substances. Beef, mutton, pork, roast fowls, bread, veal, oysters, are digested more slowly. Inasmuch as perfect digestion can only be accomplished when the digestive juices have acted for some time on all parts of the food taken, it follows that fine subdivision of food is very essential. On this account liquid food rapidly disappears from the stomach, which retains for a longer time solid masses upon which the gastric juice acts with greater difficulty. When food is cooked it swells, its fibres and solid particles are separated one from another, and it is more readily permeated by the gastric and pancreatic juices. In addition, starch becomes gelatinous, and in that form is easily digested by the

saliva and pancreatic juice. The diet of early infantile life differs from that of the adult, inasmuch as it should contain no starch. Milk, the natural food of the infant, is rich in fat, proteids, and a sugar called milk-sugar. There is in milk, however, an entire absence of starch, an article of food which the infant is destined to consume in such large quantities in later years. Moreover, during the first few months of its extra-uterine existence the child is unable to assimilate starch given with its food. On no account, therefore, must it be supplied with bread, potatoes, rice, or other vegetable food until the cutting of the teeth suggests a more solid diet. If the mother's milk be not in sufficient plenty, cow's milk diluted with one-third of water, with a pinch of sugar, may be given, or condensed milk diluted with twelve to twenty parts of water (see MILK). Condensed milk, owing probably to its very uniform composition, cannot be given alone for more than a few weeks together. It may, however, be given once or twice a day for months, and children thrive on it, when they in addition are supplied with good cow's, or still better, with their own mother's milk.

In conclusion, it may be well to consider the results which follow the neglect of the most obvious rules of dietetics. As the result of deficient food, one finds loss of muscular and nervous power, wasting of the tissues, and anæmia. If the deficiency be very great, feverish symptoms and great prostration result.

Many persons consume large quantities of food quite out of proportion to their size or activity. In this case, owing to a 'habit of digestion,' much of the food may pass through the digestive tract without being digested or assimilated. Under these circumstances the hearty eater is a wasteful eater, and is using for his own bodily needs only a fraction of the food he consumes. In addition, dyspepsia in various forms, constipation, and diarrhoea are apt to follow, indicating functional derangements of the digestive apparatus. There is often a tendency, especially in advanced years, to absorb more nourishment than is necessary for stoking the body and for replenishing ordinary tissue waste. The excess is stored up in the form of fat, which accumulates under the skin, chiefly under that of the abdomen. In addition, the muscles and internal organs are loaded with fat, the minute globules of which may be seen in the ultimate cells of which the tissues are composed. Hereditary tendency is well marked in cases of corpulency. In addition to corpulency, an excess of food is apt to engender various gastric troubles, engorgement of the liver, plethora, and an excess of effete extractions in the blood and urine. It is probable that humanity suffers more from an excess than from a deficiency of food. An excess of animal is more serious than an excess of vegetable food. The nitrogenous extractions, derived from the incomplete assimilation of meat, when present in large quantity, cause many symptoms, most of which are extremely obscure in their nature. These are provisionally spoken of as symptoms of gout. The ill effects which follow surfeit are more severe in those leading a sedentary and inactive life, bodily activity producing more efficient oxidation of the food taken. A healthy and abstemious man whose tastes have not been enslaved by the culinary art instinctively adapts his food to the requirements of his body. The cold of winter prompts the choice of substantial and energising food, while the heat of summer suggests a lighter dietary. After a country holiday, on returning to a sedentary life one at once reduces one's allowance of beef, or expects to pay the penalty that a disordered digestion is certain to exact. During the ages in which

humanity has been evolving, there has been a constant adaptation of taste and desire to the needs of the economy. The natural gustatory inclinations as a rule are a good indication of the bodily wants. As a rule wholesome things have a pleasant taste, and the reverse also holds good. It is all-important, however, that the satisfaction of mere gustatory pleasure be not allowed to monopolise too much of the energy of any individual. Under these circumstances a surfeit is certain to result. There is a well-known law in physiology to the effect that *greater* and *greater* stimuli have to be applied in order to produce a series of *equal* sensations. It follows that the excesses of the glutton and drunkard are out of all proportion to the actual pleasures these excesses produce, the wise man drinking and eating only in moderation.

See the articles on COOKERY, FOOD, DIGESTION, INDIGESTION; also Pavy, *Food and Dietetics* (1874); Sir H. Thompson, *Food and Feeding* (1880); Sir W. Roberts, *Lectures on Dietetics and Dyspepsia* (1885); Fothergill, *Manual of Dietetics* (1886).

Diet (Lat. *dies*, 'day'), a meeting of delegates or of dignitaries, held from day to day, for legislative or ecclesiastical purposes; the title was afterwards extended to such bodies themselves. The term is applied to the sessions of church assemblies in Scotland, but its chief use is as the specific title of the administrative assemblies of the German empire and some other continental states (see GERMANY).

Desertion of the Diet, in Scots law. The proceedings under a criminal libel are in Scotland spoken of technically as a diet, and when the libel is abandoned by the public prosecutor, or where he fails to appear, he is said to desert the diet. The effect of a judgment of the court declaring that the diet has been deserted, is to free the accused from prosecution under the particular libel or writ, but not to prevent a new process being raised on the same grounds.

Dietrich of Bern. See THEODORIC.

Diez, FRIEDRICH CHRISTIAN, the greatest of Romance philologists, was born at Giessen, 15th March 1794, and educated at Giessen and Göttingen, with one short interval in 1813 of campaigning as a volunteer. In April 1818 he saw Goethe at Jena, and was directed by the sage to the lectures of Raynouard and the study of the Provençal tongue. From 1822 he lived at Bonn as a *privat-docent*, and in 1830 was there appointed professor of the Romance Languages, and there he died, May 29, 1876. His first work, *Altspan. Romanzen* (1821), was followed by a series of valuable works on the Romance languages, of which the greatest are his *Grammatik der Romanischen Sprachen* (3 vols. 1836-38; 4th ed. 1877), and the *Etymologisches Wörterbuch der Romanischen Sprachen* (2 vols. 1853; 4th ed. by A. Scheler, 1878; Eng. trans. 1864). These works discussed these languages for the first time from the comparative historical standpoint, and thus formed a sound foundation for all subsequent Romance philology. See the books on Diez, his life and work, by Sachs (1878), Breymann (1878), and Stengel (1883).

Difference, CALCULUS OF FINITE DIFFERENCES. Difference implies two quantities of the same kind, and means in arithmetic that quantity which must be added to the smaller in order to produce the larger, and in algebra that quantity which must be added to either to produce the other. Thus if the quantities be the numbers 5 and 7, their arithmetical difference is 2, while their algebraical difference may be either +2 or -2. The difference -2 arises from the fact that we may in algebra ask the question what must be

added to 7 to produce 5? and the answer to this is -2.

In certain groups of problems, chiefly relating to series, differences considered in a particular manner are of peculiar importance, constituting in fact a branch of higher algebra, which took its origin in Brook Taylor's *Methodus Incrementorum* (1715), and is now called the Method of Differences or the Calculus of Finite Differences. This method we shall briefly illustrate.

Suppose it were required to discover the law of formation, and thence to continue the series of numbers:

4, 3, 0, 1, 12, 39, 88, 165.

It would be wrong to assume that only one law of formation will produce these eight numbers, just as it would be wrong to assume that only one curve could be drawn through eight given points; but for the full discussion of the difficulty here raised the reader must be referred to the chapter on Interpolation in any text-book on the subject. We shall, however, show how to find one law of formation, and use our figures to illustrate the elementary notation of the subject. The process is to take the difference between each term and the succeeding one, and so get the first series of differences, or, as it is called, the series of first differences; the process is repeated on the first differences, and so on, as follows:

No. of term,	1	2	3	4	5	6	7	8
Given Series,	u_1	u_2	u_3	u_4	u_5	u_6	u_7	u_8
	4	3	0	1	12	39	88	165
1st Differences,	Δu_1	Δu_2	Δu_3	Δu_4	Δu_5	Δu_6	Δu_7	
	-1	-3	1	11	27	49	77	
2d Differences,	$\Delta^2 u_1$	$\Delta^2 u_2$	$\Delta^2 u_3$	$\Delta^2 u_4$	$\Delta^2 u_5$	$\Delta^2 u_6$		
	-2	4	10	16	22	28		
3d Differences,	$\Delta^3 u_1$	$\Delta^3 u_2$	$\Delta^3 u_3$	$\Delta^3 u_4$	$\Delta^3 u_5$			
	6	6	6	6	6			

The line of third differences suggests a law of formation, and enables us to continue the series as follows:

	165	276	427	624
	77	111	151	197
	28	34	40	46
	6	6	6	6

It could further be shown that if u_x be the x th term of the series above, then

$$u_x = x^3 - 7x^2 + 13x - 3.$$

The operation indicated by Δ is defined by the following equation, where u_x means any function of x :

$$\Delta u_x = u_{x+1} - u_x \quad (1)$$

or, if we denote the 1 added to x by Δx , by the equation

$$\frac{\Delta u_x}{\Delta x} = \frac{u_{x+1} - u_x}{1} \quad (2)$$

or with the appearance at least of greater generality by

$$\frac{\Delta u_x}{\Delta x} = \frac{u_{x+h} - u_x}{h} \quad (3)$$

As a final example let us suppose $u_x = x^2$. Then we have, using equation (1) above,

$$\begin{aligned} \Delta u_x &= (x+1)^2 - x^2 \\ &= 2x + 1 \end{aligned}$$

This is a case of the direct problem of the calculus, but there is also the inverse problem: Of what function is $2x + 1$ the difference? The solution to this is denoted by the symbols:

$$\Sigma(2x + 1) = x^2,$$

or, strictly speaking, for reasons which we need not give, by

$$\Sigma(2x + 1) = x^2 + C;$$

and $x^2 + C$ is said to be the *integrate* of $2x + 1$.

Between the Calculus of Finite Differences and the Differential Calculus (see CALCULUS) (a title which means the calculus of infinitesimal differences) there are many important points of contrast and of similarity, which would be not less clearly appreciated if the names were changed, as Boole all but suggested, the former to Calculus of Differences, the latter to Calculus of Limits.

The methods of the Calculus of Differences are in vogue among actuaries and others in dealing with statistics such as mortality tables; and from this calculus are derived many formulæ of approximation of great practical value, such as the rules for finding the area of surfaces bounded by curved lines.

Differentiation, that organic progress which occurs when certain parts of a uniform whole become structurally different from the others, or when, in other words, the homogeneous becomes heterogeneous. Inequality in internal and external conditions of life brings about restriction of certain vital processes and the predominance of others, and as this division of function is established, diversity of structure results. Differentiation is the structural change which is associated with the physiological 'division of labour,' and the process is essentially the same whether it find expression in cells, tissues, organs, or entire organisms. See DIVISION OF LABOUR, EVOLUTION, VARIATION, &c.

Diffraction. In general, light is propagated in straight lines in a homogeneous medium; but, if it be caused to pass through an opening which is not large in comparison with the wave-length of the light, the law no longer holds. Such phenomena are said to be due to *diffraction*. The subject will be found treated at greater length under LIGHT.

Diffusion. The particles of all material bodies, except such as may be totally devoid of heat, are in rapid motion. In the case of solid bodies the excursions of any one particle are limited to a small space; but in fluids a particle may move more or less freely throughout the whole space occupied. This intermixture of molecules may occur also when different fluids are placed in contact with each other, but it may be prevented by the existence of tension at the common surface (see SURFACE-TENSION and CAPILLARITY). When it does occur, the fluids are said to *diffuse* into each other.

Diffusion of Liquids.—The diffusion of dissolved salts may obviously be considered under this heading. The phenomenon may be conveniently studied by introducing a strong solution of some highly-coloured salt, such as bichromate of potash, into the bottom of a tall glass cylinder nearly filled with water. The rate of diffusion varies with the nature of the liquids. Graham was the first to investigate the subject carefully. He filled a number of similar glass vessels with solutions of different salts. The mouths of these vessels were carefully ground so that they could be closed by means of glass plates. The different vessels were then placed in equal glass jars, and covered with water to a definite extent. Next the glass covers were cautiously withdrawn, and the diffusion was allowed to go on for a certain time. The rate at which each liquid diffused was thus obtained. Graham found that, for any one solution, the rate is proportional to the gradient of concentration—i.e. to the rate at which the quantity of salt dissolved per unit-volume varies per unit-length. Thus the law regulating diffusion of liquids is analogous to that which regulates the conduction of heat in a homogeneous solid. Hence the equations obtained by Fourier in his *Théorie de la Chaleur* apply to the problem under consideration.

Graham found also that rise of temperature

greatly increases the effect. He divided substances into two classes, *Colloids* and *Crystalloids*, the members of the first class diffusing very much more slowly than those of the second. His investigations have been much extended by more recent observers employing various methods of observation.

If two miscible liquids be separated by a membrane of bladder or of parchment paper, &c., diffusion takes place through the septum at rates which are usually very different for different liquids. This phenomenon is known as *Osmose* (q.v.). It was first shown by Nollet that, if a vessel filled with alcohol be closed by a piece of bladder and placed in water, the diffusion of the water is so much more rapid than that of the alcohol that the bladder is burst because of the increase of the contents of the vessel which it closes. By this means the various constituents of a mixture of colloid and crystalloid substances may be separated to any desired extent. The rate at which liquids diffuse into each other through a septum depends greatly upon the molecular action between them and the septum.

Diffusion of Gases.—If two flasks, each filled with a different gas at a given pressure and temperature, be placed in communication with each other, the gases will be found to interdiffuse. The rate of interdiffusion is shown by theory to be nearly in inverse proportion to the square root of the product of the densities of the two gases, and the experimental results are in accordance with the theory.

Effusion of Gases.—This is exhibited in the passage of a gas into vacuum under constant pressure through a small opening in a very thin plate otherwise impervious to it. The work done in the passage of a given volume of the gas is proportional to the pressure, and the equivalent kinetic energy is proportional to the product of the density and the square of the speed of effusion. Hence the speed for a given pressure varies inversely as the square root of the density. Graham showed that this result of theory is closely realised by experiment. He showed, further, that when a discrepancy exists, it is due to the finite thickness of the plate.

Transpiration of gases is the term to the passage of gases under pressure through a fine capillary tube. This subject was also investigated by Graham, who found that the rate of passage is not affected by the material of the tube. This seems to indicate that the tube becomes coated internally with a thin film of gas, so that the opposition to the flow of gas is due to Viscosity (q.v.).

The rates at which different gases pass through fine unglazed earthenware are inversely as the square roots of their densities. Hence we have a means of separating gases the densities of which are different (see ATMOLYSIS). If the septum be made of caoutchouc, which is not porous, the passage of gases still occurs. The gas seems to combine with the matter of the septum on the one side, to diffuse through it, and finally to be given off on the other side. The passage of some gases, such as carbonic oxide, through hot cast-iron is analogous.

Digamma is the name given by the grammarians of the 1st century to *vau*, the sixth letter of the primitive Greek alphabet, which had become obsolete, and was only known to them from inscriptions. The name was given owing to a fancied resemblance of its form φ to a double gamma. Its sound was something like that of our *w*. It is found in Peloponnesian inscriptions as late as the 6th century B.C., but it had disappeared from the alphabet of Attica before the date of the oldest inscriptions—i.e. before the

middle of the 7th century B.C., although, as Bentley has proved, it must have been in use at the time when most of the Homeric poems were composed. It appears as the letter F in the Latin alphabet, which was derived at a very early period from the alphabet of Eubœa. In later Greek, though discarded as a letter, it is retained in the form ͵ as the numeral for 6. See the articles on F and V.

Digby, a small seaport of Nova Scotia, on St Mary's Bay, reputed for its curing of a variety of small herrings or pilchards ('Nova Scotia sprats'). Pop. 1951.

Digby, SIR KENELM, was born at Gayhurst, near Newport Pagnell, 11th July 1603. His father, Sir Everard Digby (1578-1606), in 1592 came into a large estate, but seven years later turned Catholic, and was hanged for his part in the Gunpowder Plot (q.v.). Kenelm himself was bred a Catholic, but in 1618, after a half-year in Spain, entered Gloucester Hall, Oxford (now Worcester College). He left it in 1620 without a degree, and spent nearly three years abroad, in Florence chiefly. At Madrid he fell in with Prince Charles, and following him back to England, was knighted, and entered his service. In 1625, after a singular courtship, he secretly married 'that celebrated beautie and courtezane, Venetia Stanley (1600-33), who had been his playmate in childhood. With two privateers he sailed in 1628 to the Mediterranean, and on 11th June vanquished a French and Venetian squadron off Scanderon. On his beloved wife's death he withdrew to Gresham College, and there passed two hermit-like years, diverting himself with chemistry and the professors' good conversation. Meanwhile he had professed the Protestant faith, but, 'looking back,' in 1636 he announced his reconversion to Archbishop Laud; and his tortuous conduct during the Great Rebellion was dictated, it seems, by his zeal for Catholicism. He was imprisoned by the Parliament (1642-43), and had his estate confiscated; was at Rome (1645-47), where he finished by 'lecturing at his Holiness,' and thrice revisited England (1649-51-54), the third time staying two years, and entering into close relations with Cromwell. At the Restoration, however, he was well received, and retained his office of chancellor to Queen Henrietta Maria. He was one of the first members of the Royal Society (1663), and died 11th June 1665.

'The very Pliny of our age for lying,' said Stubbes of Digby, whom Evelyn terms 'an arrant mountebank.' Yet he was a friend of Descartes and Sir Thomas Browne (q.v.); he could appreciate the discoveries of Harvey, Bacon, and Galileo. In the *Dictionary of National Biography* (vol. xv. 1888) Mr S. L. Lee points out, that 'as a philosopher—an Aristotelian—Sir Kenelm undoubtedly owed much to Thomas White; and he questions whether his much-vaunted 'powder of sympathy' was not really invented by Sir Gilbert Talbot. This powder—Digby professed to have learned the secret from a Carmelite who had travelled in the farthest East—was made of vitriol, and applied to a bandage, not to the wound itself. Anyhow, Digby's Discourse thereon (1658), like his *Treatise of Bodies and of Man's Soul* (1644), contains much that is curious, if little of real value; whilst in his *Discourse concerning the Vegetation of Plants* (1660), the chief of his other twelve works, he 'is said to have been the first to notice the importance of vital air or oxygen to plants.' See his bombastic *Memoirs*, dealing with his courtship (edited by Sir Harris Nicolas, 1827), and his *Journal of the Scanderon Voyage* (edited for the Camden Society by John Bruce, 1868).

Digby, KENELM HENRY, was born in 1800, youngest son of the dean of Clonfert. Having entered Trinity College, Cambridge, he took his B.A. in 1819, and three years later published the *Broad Stone of Honour*—'that noble manual for gentlemen,' as Julius Hare called it, 'that volume which, had I a son, I would place in his hands, charging him, though such admonition would be needless, to love it next to his Bible.' It was much altered and enlarged in the 1828 and subsequent editions (the latest 1877), its author having in the meantime turned Catholic. He died in London, where most of his long life was spent, on 22d March 1880. Of fourteen other works (32 vols. 1831-74) all the last eight were poetry.

Digest, a name often given to the Pandects (q.v.) of the civil or Roman law, because they contained 'Legalia præcepta excellenter digesta.'

Digester, PAPIN'S, is a strong boiler with a closely fitting cover, in which articles of food may be boiled at a higher temperature than 212° (100° C.). As its name implies, it was invented by Papin (q.v.), and a common form is the *Autoclave*, fig. 1, where the lid can be turned round under clamps or ears, and thus be rendered steam-tight. Another form is given in fig. 2, where a portion of the side

Papin's Digester.

is removed to exhibit the interior. The lid, A, is fastened down by a screw, B, and the steam generated in the boiler is allowed to escape at a stopcock, C, or by raising the weighted valve, D. The increased pressure to which the contents of the boiler are exposed causes the boiling-point of the water to rise to 400° (204° C.), and occasionally higher. The digester is of great value as a means of preparing soups of various kinds, and especially in the extraction of gelatin from bones.

Digestion is the change which food undergoes in order to prepare it for the nutrition of the animal frame, and is carried on in the higher animals in the DIGESTIVE SYSTEM. In some of the lowest forms of animal life (amebæ) particles of food may be drawn into the body (which possesses no special organs at any part of its surface), and may then be digested. In higher organisms, however, parts have become evolved, which serve more especially the function of digestion. Thus in the common sea anemone there is a simple pouch which leads inwards from the centre of the cluster of tentacles. Into this fish and other food are drawn and digested, while the undigested parts are afterwards voided through the same aperture by which they entered. In still higher organisms, man himself included, this simple pouch is changed into a complex and greatly elongated tube, which is provided with one aperture (the mouth) by which food enters, and another aperture (the anus) through which undigested matter leaves the body. The whole digestive system is lined with a soft mem-

brane, which is richly supplied with blood-vessels. This membrane is called the mucous membrane, and from it is secreted by the glands which it contains a viscid substance called mucus. If the finger be thrust into the back of the mouth, and the mucous membrane gently scraped, the fluid which will adhere to the finger is seen to be viscid: it is secreted by the glands of the mouth. Not only mucus, but many other substances useful in digestion are formed by little glands in the mucous membrane, so that the whole digestive system is bathed during digestion with fluid having a digestive action on the food. In addition there are other glands, such as the salivary, the liver, and the pancreas, which we may look upon as glands of the mucous membrane which have enormously developed. To so great an extent have they increased in size that they have got far outside the digestive system, and have become situated in neighbouring parts of the body, only connected with the digestive system by their ducts or elongated mouths.

Fig. 1.—Section through Mouth, Nose, &c. :

a, sphenoid bone; *b*, Eustachian tube; *c*, soft palate; *d*, uvula; *e*, nasal passage; *f*, upper jaw; *g*, lower jaw; *h*, epiglottis; *m*, mouth.

Through these ducts their secretions, like that of the microscopic mucous gland, pour into the cavity of the digestive system. Outside the mucous coat we have the muscular coat, the function of which is to move the food onwards in its course, and to mix it with the digestive juices. In the mouth, throat, and the upper part of the gullet, the muscles which move the food onwards, as in swallowing, are, when examined by the microscope, seen to be transversely striped, and like other striped muscles their contraction is rapid. In other parts of the digestive system, however, the muscular coat consists of smooth muscle, and like all other smooth muscles this coat contracts slowly. On this account the food rapidly swallowed passes very slowly along the rest of the digestive system.

Having shown that the digestive system is a mucous-muscular tube, we may now consider it more in detail. The mouth (fig 1, *m*) is lined with mucous membrane, and into it is poured the secretion of three pairs of salivary glands—the parotids, situ-

ated in front of the ear; the submaxillary, within the angle of the lower jaw; and the sublingual, under the tongue. The mouth in most animals is provided with hard tissues—teeth, beaks—for the subdivision of food before it is swallowed. Vegetable feeders, eating tough grains, roots, and fibres, have large molar or grinding teeth, while the carnivora have these same teeth modified so as to present a cutting edge, with which and their pointed canines meat is torn and cut into pieces, which are then swallowed (see **TEETH**). The mucous membrane of the mouth is covered externally by the muscles of the cheek and lips. Into its cavity the muscular tongue projects. On looking into the mouth with a looking-glass, one sees back into the throat. The entrance to the throat will be observed to be bounded at the sides by two muscular curtains passing downwards obliquely to the sides of the root of the tongue. These are termed the anterior pillars of the fauces, and behind them, one on each side, are masses of lymphoid tissue, subject to enlargement, called the tonsils. Above, another curtain hangs down. It is called the soft palate, and separates the mouth from the hinder part of the nasal cavity. Projecting from its centre is a little cone called the uvula (fig. 1). The cavity of the pharynx, or the interior of the throat, is another cavity lined by mucous membrane, with muscular walls. These muscles constrict it (constrictors). Below, the cavity passes into the gullet or oesophagus, and in front of this tube runs the windpipe which communicates with the pharynx through the larynx, or organ of voice. Food will pass through the pharynx into the gullet; and air, during respiration, passes through the pharynx on into the larynx and windpipe; a valve, called the epiglottis, partly closes the aperture of the larynx. The pharynx is common, therefore, both to the digestive system and the respiratory passages.

Above, the pharynx communicates, as before described, with the mouth and also with the nose. One can demonstrate this latter fact by drawing smoke into the mouth, and expelling it by the nostrils. This communication is closed during the act of swallowing, and also during the singing of pure vowel-sounds, such as *a*, *o*, *u*, and the closure is effected chiefly by the elevation of the soft palate, which acts as a valve. The pharynx communicates in addition with the middle ear by the Eustachian tubes, and this may be rendered evident if the mouth and nose be closed, and a violent expiratory effort made at the same time. As the pressure of air within the throat is increased, the Eustachian tubes which

Fig. 2.—Human Alimentary Canal :

previously were collapsed now become distended, and a little wave of air at high pressure is forced into the middle ear, causing a buzzing sound. Occasionally the middle ear communicates with the external air through congenital or acquired apertures in the membrana tympani. In these cases smoke may be propelled from the throat out of one or both ears.

The gullet or oesophagus (figs. 1, 2, and 3) is a long tube passing from the pharynx to the stomach. Its mucous coat is loaded with very large mucous glands, which secrete a quantity of very viscid mucus. Its muscular walls contain striped fibres in the upper, unstriped in the lower part. The stomach itself is a greatly dilated part of the digestive system. Its shape is indicated in the fig. It may be said to consist of two parts, even in the human subject; a more complex arrangement is found in many animals, such as the ruminants. The large dilated portion into which the gullet opens is termed *cardiac*, and the opening the cardiac or oesophageal opening. The narrow part opening into the duodenum is the pyloric part, and the opening the pyloric opening. The whole is lined with mucous membrane, which, in the empty stomach, is thrown into projecting folds or *rugae*, but these folds are effaced when the organ is distended with food (fig. 3). In the

Fig. 3.—Section of the Stomach :

membrane are innumerable glands, which secrete the digestive juices of the stomach (fig. 4). If the surface of the membrane be examined with a strong pocket-lens, the apertures of these little glands may be seen. They run down from the surface into the deeper parts of the mucous membrane. They are lined by secreting cells. The greater number of glands situated in mucous membranes have the simple structure diagrammatically represented in fig. 4. Each gland has a mouth or short duct lined by cells. Below this the little tube is lined by cells which secrete the juice peculiar to the gland. This secreting part sometimes branches. Outside the gland blood-capillaries ramify, which supply the gland with nourishment, enabling it to manufacture the substances which it secretes. The gastric juice is acid, and the chief acid secreted is hydrochloric acid. This is formed at the cardiac, but not at the pyloric end. The substance called *pepsine*, which is necessary for digestion, is secreted by the whole of the glands. The cardiac glands therefore secrete both substances, and they possess two sorts of cells, those which form the hydrochloric acid being bigger and more granular than the other sort which secrete pepsine. The pyloric glands secreting pepsine have only one kind of cell similar to the pepsine-secreting cell of the cardiac end. Outside the vascular and glandular mucous coat, and united to it by a loose delicate

layer—submucous coat—is the muscular coat. This is similar to that of the rest of the alimentary canal, except that there are in addition to the circular and longitudinal fibres, many oblique fibres. The circular fibres are very thick indeed at the pyloric aperture, forming a circular sphincter band, which contracts and keeps back the food in the stomach until gastric digestion is nearly completed.

The food, now called the *chyme*, passes into the small intestine, a tube some 20 feet long. This tube, besides the muscular and mucous coats, possesses in addition an external coat of loose fibrous tissue, covered by a single layer of flat epithelial cells. This coat is prolonged into, and helps to form the mesentery, a membrane connecting the intestine with the abdominal walls, which are lined with a similar fibro-epithelial coat. This membrane is called the peritoneum, and is sometimes inflamed (peritonitis) as a result of cold, injuries, &c. The small intestine is somewhat arbitrarily divided into three portions—the upper (duodenum), the middle (jejunum), and the lower (ileum). In all parts the muscular coat is similar to that of the rest of the digestive system. The mucous coat contains glands very like the pyloric glands of the stomach, called Lieber-

Fig. 4.

kühn's follicles. These, however, rarely branch. They secrete the intestinal juice. In the duodenum, one finds in addition highly-branched glands called Brunner's. These extend right down into the submucous coat. Little is known concerning their function. In both the mucous and submucous coats, and generally involving both layers, are found masses of tissue—lymphoid—similar to that found in a lymphatic gland (fig. 6). These are termed solitary glands, but it must be understood that they do not secrete any juice concerned in digestion. Their function is probably connected with the blood and the blood-corpuscles. Collections of these solitary glands,

Fig. 5.—The under surface of the Stomach and Liver, which are raised to show the Duodenum and Pancreas : st, stomach; p, its pyloric end; l, liver; g, gall-bladder; d, duodenum, extending from the pyloric end of the stomach to the front, where the superior mesenteric artery, sm, crosses the intestines; pa, pancreas; sp, spleen; a, abdominal aorta.

forming oblong patches about two inches long, are called Peyer's patches. These are affected in typhoid fever. In addition to the follicles of

Lieberkühn and the glands of Brunner, there are two very important glandular structures, the liver and the pancreas, which pour their digestive juices into the small intestine (fig. 5). The bile, which is the secretion of the liver, is formed continually by that organ, but the amount thus formed is greatly influenced by the kind and quantity of food taken. It passes out of the liver by the two hepatic ducts, and much of it passes by the cystic duct into the gall-bladder, where it is stored up.

Fig. 6.—Section of Intestinal Mucous Membrane : L, lacteal in centre of villus; E, epithelium covering villus; B, blood-vessels represented; F, follicle of Lieberkühn; S, part of a solitary gland; M, muscular fibres.

From this the bile passes into the common bile duct, which joins the duct of the pancreas, and the two open into the duodenum by a common aperture. The bile is to be looked upon not only as a digestive juice, but as a drain or channel of excretion, whereby effete and useless matters are removed from the body. The flow of bile is easily restrained, as by inflammation of the duct, or the presence of a tumour pressing on the duct, or a gall-stone. In this case, the bile already formed is reabsorbed with the blood, through the lymphatics, and we have jaundice due to absorption of the colouring matter of the bile. The secretion of bile goes on before birth; the meconium of infants consisting chiefly of biliary matter. The pancreas is very similar in structure to a salivary gland. It secretes the pancreatic juice which pours with the bile into the digestive system. The mucous membrane of the small intestine contains, in addition to the structures already mentioned, little projections called villi (fig. 6). These are not, to any great extent at least, secretory, but they are important absorbents. This property they share with the whole of the digestive system, through any part of which, and especially through the walls of the stomach and small intestine, digested matter passes into the numerous blood-capillaries which form everywhere a dense network. The villi are peculiar, however, for each one contains, in addition to blood-vessels, a small lymph-vessel or lacteal. Nearly all the fat absorbed by the digestive system is taken up by the little cells of the villi, and passes on into the lacteals, and thence to the blood (fig. 7). If some osmic acid, which blackens fat, be poured into the intestine of a milk-rabbit, killed during active digestion, and if the villi be examined with a microscope, they will be seen to have been blackened, especially at their

tips, while the rest of the intestine will have preserved its ordinary colour. On further examination it will be seen that the fat has been taken up in microscopic globules by the cells covering the villi, and that they are passing, in a way which is as yet not definitely settled, into the central lacteal.

The small intestine is a tube of great importance, and in order to increase its total area, the mucous membrane is elevated, in the upper part, into transverse folds (the valvulae conniventes, fig. 8).

The unabsorbed food, mixed with the various secretions we have mentioned, now passes into the large intestine, when both digestion and absorption go on, although to a less extent. The large intestine is only 5 feet in length, but its girth is much greater than that of the small intestine. It commences with the caecum, a dilated part, into which passes a little blind canal (the vermiform appendix), a large and important structure in some animals. The food remnant (faecal matter) is prevented, under ordinary circumstances, from passing back into the small intestine, by a double fold of mucous membrane (the ilio-caecal valve, fig. 9). The large intestine ascends on the right side (ascending colon), crosses over to the left side (transverse colon), and descends again (descending colon), and makes a bend (sigmoid flexure), and finally terminates in a somewhat enlarged portion (rectum).

Fig. 7.—The Top of a Villus : Fat globules are represented as passing through one of the epithelial cells, F, on through the tissue of the villus, I, into the central lacteal, L.

Fig. 8.—Small Intestine distended and hardened by alcohol, and laid open to show the valvulae conniventes.

Fig. 9.—Caecum inflated, dried, and opened to show the arrangement of the valve : a, termination of the ileum; b, ascending colon; c, caecum; d, a transverse constriction projecting into the caecum; e, lips of the valve separating the small from the large intestine; g, the vermiform appendix of the caecum.

The anal aperture is closed by muscles, an internal sphincter of non-striped, and an external of striated fibre. The mucous membrane of the large intestine differs from that of the small intestine in containing no villi, or Brunner glands. Lieberkühn's and solitary glands are present, but the aggregation of the latter into Peyer's patches is nowhere to be found.

Movements of Food in the Alimentary Canal.—

When food is taken into the mouth it is at once swallowed, unless it is in the solid form. In this case it is chewed or masticated; the use of which is to divide the solid fragments taken into a convenient size for swallowing, for which purpose it, in addition, is mixed with the viscid saliva and juices of the mouth. The chewed food, moreover, is more easily digested, inasmuch as the gastric and other juices can act more readily upon finely divided than upon larger masses of food. Many animals can hardly be said to masticate; such are the carnivora (dog, cat, &c.), and they are not provided with grinding teeth. In most animals living on vegetable food, which frequently consists of hard grains, roots, and fibres, large flat grinding molars are found. In these animals, not only is the food finely divided in the mouth, but the food, largely consisting of starch, is partially digested by the saliva. In mastication, the head is firmly fixed by the powerful muscles of the neck, while the lower jaw is moved upon the upper. The lower jaw is approximated to the upper by powerful muscles (the temporal, masseter, and internal pterygoids), which pass upwards, and are attached to the side of the head and face. Their contraction may be felt by placing the hand in front of the ear and voluntarily contracting the jaws. The lower jaw is depressed by muscles which pass down the front of the neck. Most of these spring from the hyoid bone, which may be felt deep in the tissues of the neck above the 'Adam's apple.' Rotating movements and those of protrusion and retraction of the jaw are produced chiefly by the action of the pterygoid muscles. It is obvious that during mastication the food would naturally tend to escape from between the grinding surfaces of the teeth, and would collect within the mouth and outside the gums. This is prevented, however, by the muscles placed in the substance of the cheeks (buccinators) and lips (orbicularis oris). These keep the cheek and lip walls closely opposed to the outside of the teeth. On this account food will only escape from between the grinders into the interior of the mouth, from which it is collected and pushed back between the teeth by the muscular tongue.

The very complex muscular movements just described result from very perfectly co-ordinated nervous impulses, which pass from the brain to the muscles, and cause and regulate their contractions. One can masticate 'at will'—that is to say, one can consciously cause the muscles to contract. In order that the mastication may be effective, however, it is necessary not only to know the sizes, but also to be aware of the ever-changing positions of the particles of food. This is effected by sensory nerves, which pass to the brain from the mucous membrane of the mouth. Although mastication is frequently voluntary, yet, like most other voluntary actions frequently performed, it can be performed reflexly. In this case the sensory impulses pass from the mucous membrane to the brain, and initiate appropriate motor impulses which pass to the muscles, without exciting attention and special volition in their passage.

As a result of mastication, the food is gathered in the form of a round moist bolus on the upper surface of the tongue (see fig. 1). It is now ready to be swallowed. In the first place, it is pushed backwards by the tongue, and seized by muscles, many of which are attached to the hyoid bone, which can be felt to move during their contraction. According to the most recent investigation, the bolus is propelled with great rapidity through the pharynx and gullet into the stomach. If the finger be placed upon the hyoid bone, or Adam's apple, and the ear placed against the upper third of the back of a patient, the movement of the hyoid bone indicat-

ing the commencement of swallowing is almost coincident with the passage of food down the gullet, which produces a very audible sound. Following the propulsion of the food downwards, there is a wave of contraction, which, commencing in the pharynx, travels downwards through the gullet. This, however, is comparatively slow. It is seen then that swallowing is not due to the falling of liquids down the throat. A horse drinks 'up hill,' and the jugglers, or indeed any one, can drink or swallow with the head vertically downwards.

When the food has reached the back of the mouth, the rest of the act of swallowing occurs irrespective of the action of the will. The nerves, which commence in the mucous membrane of the pharynx and gullet (sensory branches of vagus), carry impressions to the brain, which disengage of themselves the appropriate muscular movements without necessarily involving either the will or consciousness. Thus, in alcoholic stupor, or fainting from drowning, in both of which conditions consciousness is suspended, food and liquid placed at the back of the mouth are at once swallowed.

There is a possibility that during swallowing the food may go the wrong way—i.e. it may pass into the larynx and windpipe. It will be seen from the diagram that the food in its passage to the gullet must actually pass over the aperture of the larynx. It is prevented from passing into it by the elevation of the larynx (this can be felt by the hand placed on the throat), which pushes its aperture against and under the back of the tongue, which at the same time is pushed backwards. In addition, there is a valve called the epiglottis, which is pushed down over the larynx by the movement just described, and by muscular fibres, which act upon it for that especial purpose. If the epiglottis be destroyed, as by ulceration, gun-shot wounds, &c., it is necessary for the patient to have the food he takes carried over the aperture of the larynx into the gullet by a feeding-tube. It is obvious that one cannot speak with the larynx shut, and with the larynx open we cannot safely swallow. Food is prevented from passing into the nose by the elevation of the soft palate which meets the constricting pharynx, and shuts off the cavity of the nose like a valve (fig. 1).

The walls of the stomach and intestine are, like the gullet, provided with muscular fibre. An external layer passes in the length of the gut, and within this is a circular layer. These muscles, unlike the muscles of the limbs, contract slowly on stimulation, and they are outside the domain of voluntary action. During digestion they contract peristaltically, urging the food towards the rectum. The peristaltic waves may begin in any part of the gut and pass slowly downwards, followed at varying intervals by other waves. It is probable that what is called antiperistaltic waves may occasionally occur, tending to bring the food back towards the mouth, for bilious matter is frequently vomited, the bile having in all probability passed upwards into the stomach by antiperistalsis from the duodenum.

Eructations are frequently caused by antiperistalsis, and by a movement of this kind food is brought back into the mouth for further chewing in the ruminants (sheep, oxen, &c.). The peristalsis is particularly active during digestion, and is produced in great part by the food stimulating the mucous membrane. If a portion of the intestine or the stomach be removed from the body, peristalsis may continue or may be produced artificially, especially by irritating the mucous membrane. In the body the canal is under the influence of additional nerves (vagus), through which fibres the digestive processes are chiefly regulated among themselves.

The peristalsis in the stomach is combined by irregular churning movements.

The act of vomiting is a reflex nervous act. It can be excited by stimulating the branches of the vagus nerve, which are distributed to the stomach, as when indigestible and irritative food is taken; or emetics, such as mustard, hot water, or a hot saline solution, tartar emetic, ipecacuanha, sulphate of zinc, and alum are administered. By tickling the back of the throat with a feather, the glossopharyngeal nerve is stimulated, and vomiting may readily be produced. It is of frequent occurrence when painful irritation of the uterine nerves in pregnancy, of the nerves of the liver and kidneys during

Fig. 10. — Sensory Nerves concerned in Vomiting:

Nerves come to vomiting centre V, through spiral cord SC, from pharynx P, lungs L, gall-bladder G, stomach S, kidney K, intestine I, and bladder B.

The diaphragm—the muscle which separates the thorax from the abdomen—then becomes pressed down upon the abdominal contents, and assists in the act of vomiting. Cases in which irritating or poisonous substances are swallowed are so frequent, that every one should be aware that a large quantity of hot liquid, especially if it contain much salt, or some mustard, forms a safe and speedy emetic. Ice is a valuable sedative, and often prevents vomiting. The undigested food when it reaches the lower part of the intestine (rectum), excites sensory nerves which carry impulses to the brain and spinal cord. A feeling of distension results, and voluntary contraction of the abdominal muscles and of the diaphragm—an inspiration usually taking place—expels the undigested matter. This voluntary effort is aided by the contraction of the bowel itself, and by the relaxation of the band of muscular fibres (sphincters) which, during the intervals between evacuations, remain contracted.

In many animals, such as the sheep, ox, and camel, the stomach consists of several cavities communicating with one another. In the ox and sheep both the cardiac and the pyloric portions are each subdivided into two compartments. The cardiac part consists of a very dilated cavity, the paunch (rumen), into which the food is passed as soon as swallowed. In addition there is a smaller part, the reticulum (honeycomb), so called from the folds of lining mucous membrane which intersect, forming a reticulum. The pyloric half is divided into two

parts. The psalterium (maniples), so called from the lamellated appearance of its mucous membrane, communicates with the last division, the rennet stomach (abomasum, fig. 11).

Fluid passes either into the first, second, or third parts of the stomach, and thence on into the fourth. Solid matter, such as grass, roots, &c., passes either into the paunch or reticulum. This is mixed with the saliva swallowed with it, and in addition it is mixed with juices formed by the mucous membrane of these cavities. When the animal has finished feeding, it lies down and rumination commences. Due in part to the contraction of the abdominal muscles and diaphragm, the food is propelled in the form of rounded pellets from the paunch and reticulum up into the mouth. The pellets are there thoroughly masticated, and are returned in a pulpy condition to the stomach. Now, however, the food passes into the psalterium, and finally into the rennet stomach. It will be seen, therefore, that the consistency of the food determines into which part of the stomach it passes. The walls of the stomach near the gullet are thrown into two folds

Fig 11.—Compound Stomach of Ox:

or lips which, when in contact, form a tube leading from the gullet into the psalterium. Along this tube the masticated and fluid food can pass. The mouthfuls of grass which are first swallowed pass between their lips, and find their way at once into the paunch or reticulum.

In the bird some interesting modifications in the structure of the alimentary canal are seen (fig. 12). The gullet at about the middle of its course is provided with a pouch or crop. Into this the food passes, and is bathed by a secretion formed by its glands. It is then propelled onwards into a dilated cavity, the proventriculus, and is acted on by digestive juices. Thence it passes into the gizzard. This cavity is provided with muscular walls of enormous thickness in the case of birds that are vegetable-feeders. It is lined by thick and corneous epithelium, and in its interior are generally found pieces of stone, chalk, &c. The gizzard is a powerful mill, which grinds the food into a soft pulp, upon which the digestive juices can readily act (see BIRD).

The Action of the Digestive Juices.—By digestion is meant that process by which food is rendered capable of passing through the walls of the digestive system into the blood-vessels and lymphatics, in such a form that it may be of use to the economy. The most essential change which food undergoes is one of solution. Albumen, starch, fat, and other food-stuffs are quite insoluble in the circulating fluids of the body, and were they injected into the blood they would simply block up the smaller blood-vessels. During digestion these pass either into nearly allied chemical substances which are readily dissolved in water, or in the case of fat partly into a soluble soap, and partly into a state of microscopically minute subdivision. It is not sufficient, however, merely to have a soluble food-stuff in order that it may be absorbed and used by the body. Cane (table) sugar is soluble in water, but it is of no use as cane-sugar to the body. If injected into the blood-vessels, it is at once secreted by the kidneys. During digestion it is converted into another sugarless soluble, but in a form which can be used by the economy.

It must clearly be understood that food introduced into the stomach is not received into the system. It is still 'outside the body.' It is only when it has become absorbed, and has passed in a suitable form, carried by the blood, to the tissues of the brain, muscles, &c., that it is made use of in so-called vital manifestations. The relief and stay that a meal gives is chiefly due to nervous action, the result of gastric distension. Clay and other non-nutritive matter may be swallowed, and will temporarily produce the same effect.

The digestion of food is brought about by the action of juices, the saliva, the gastric, pancreatic, intestinal, &c. These are mixed with the finely divided food by the movements of the alimentary canal. The digestive juices are in all cases secreted by the microscopic cells which line the various glands opening into the digestive system. The digestive juice, whatever be its source, contains either an acid substance or an alkaline one, and in addition a substance termed an unorganised ferment. These ferments differ in many particulars from the organised ferments (bacteria, micrococci), found in putrefaction, diseases such as anthrax, scarlet fever, cholera, &c. The latter are whole living cells, having definite parts or organs. They live and multiply, consume, and excrete in the fluid they inhabit. The digestive ferments are not whole cells, they are the *products of cells*. They are not the broken-down useless substances, such as carbonic acid, water, &c., which all cells give out, and which an animal, like man (an aggregation of cells), excretes. They consist of very complex active matter, of which we know almost nothing, and which we class with some other substances of which we know little more, under the head 'albuminoids.' These ferments in fact possess many of the qualities of cells themselves. They are killed by the temperature of boiling water, like all other living things. They have a certain range of temperature, within which alone they evince activity, and within the limits of that range they are more active the higher the temperature. Then again they require the presence of water, in which fluid they are soluble. In their action they seem to be hydrolytic, that is, they produce important changes in the substances they attach by, amongst other things, adding the elements of water. These digestive ferments, together with the other constituents of the digestive juices, are secreted by the cells of the digestive glands. If we study these glands and their cells with the microscope, they all present several points of similarity. Each gland has a duct, which, as in the case say of the salivary glands, divides into several branches. The duct,

or its branches in the latter case, terminate in the secreting tubules of the gland. These are little tubes, which are lined by the secreting cells, leaving only a small cavity in the centre of each tubule for the escape of the secretion into the duct. Outside the tubule there is a dense network of fine blood-capillaries, from which the liquor of the blood escapes, bathing the gland and the cells within it. These imbibe the liquor, and they have almost certainly the power of selecting such constituents of it as they require. The substances derived from the blood are used by the cells, which manufacture the juice which they excrete. The constituents of the excretion are not found, it will be observed, in the blood; they result from chemical processes which go on within the cells, which use blood as a raw material. The cells are very small, being about $\frac{1}{1000}$ th to $\frac{1}{2000}$ th of an inch across. They have each a very thin envelope, within which the finely granular contents of the cell are seen. In the centre is a kernel or nucleus. During digestion the cell enlarges, and granules appear in it. These are the manufactured products: they are discharged into the duct of the gland.

We have now to consider how it is that the glands are regulated in their secreting powers, how it is that at certain times, and in sufficient quantity, the secreting juice is poured into the digestive system. This is brought about by the action of the nervous system. Although in some cases—e.g. the stomach, local nerve-cells placed in the walls of the digestive system itself, seem to regulate in part the secretion, yet in all cases nerve-cells placed in the brain are chiefly concerned. It was thought at one time that the brain acted by causing the blood-vessels of the gland to enlarge, and in consequence the food-supply and secretion of the gland to become greater. That this is not the whole truth, is shown by the administration of belladonna. If a rather large dose of this drug be taken, the mouth becomes very dry and unpleasant, and it is difficult to speak and to swallow. In other words, the cells of the salivary glands are paralysed, and the customary flow of saliva is for the time being at an end. It is found, however, that during this condition the blood-vessels are by no means contracted. This experiment, together with others, suggests that although during the secretion of a digestive juice the blood-vessels dilate, the activity of the secreting cells is not always associated with the condition of the blood-vessels. The latter are undoubtedly under the influence of nerves (vaso-motor) which regulate their condition, and it is probable that the secreting cells are themselves under the influence of other nerves, which are special secreting nerves. We have already seen that in the case of the movements of the digestive system, the motor-impulses which started from the central nervous system were called into action by sensory impulses starting from the mucous membrane of the digestive system. So in like manner the nervous impulses which pass to the blood-vessels and the glands are caused, in the first instance, by sensory impulses from the mucous membrane. If food be taken into the mouth, especially if it be 'tasty,' a secretion of saliva rapidly follows, and even the tickling of the mouth by a feather, or the stimulation of the mucous membrane with electricity, will produce the same result. In this case sensory impulses pass to the brain through such nerves as the lingual and glossopharyngeal, and reflexly excite the glands through the medium of the brain, the outgoing impulses passing through nerves such as the chorda tympani (fig. 13). See BRAIN. In the case of salivary secretion, the smell or sight of food may excite a secretion. In this case the sensory impulses pass from the nose or eye along the nerves of these organs to the brain. When the thought of food produces a flow,

this is due to the recalling of previous sight and smell impressions in the brain.

When food is passed into the stomach, secretion occurs. This too may result from mechanical irritation, as when through an opening (fistula) the mucous membrane is brushed with a feather. In all cases the stomach, pale before, becomes suffused with blood, and the gastric juice is poured out.

Fig. 13.—Nervous Mechanism of Secretion :

B, brain; C, spinal cord; S, nerve passing from mucous membrane of mouth to brain; SS, nerve passing to cell in salivary gland; VM, nerve passing to blood-vessels of gland.

The flow of the intestinal juice, the pancreatic juice, and bile, all follow the stimulation of the mucous membrane, and in all cases the blood-vessels enlarge so as to give the cells a good supply of food, although, as we have seen, they themselves actually pass into a condition of activity, as a result of the influence of special secreting nerves.

We have now to consider the digestion of food-stuffs, and the parts that the various glands play in this important process. For our present purpose it is sufficient to speak of foods as belonging to four classes: (1) Proteids—albumens; globulins, &c.—e.g. the white of egg, the chief constituent of meat, the gluten of bread. (2) Carbohydrates—starches, sugars, gums—e.g. potato-starch, cane or grape sugar. (3) Fats and oils—e.g. suet, marrow, olive-oil. (4) Minerals—e.g. water, table-salt, iron, phosphates. See also DIET, FOOD.

Some few substances are absorbed without being digested at all; they do not need to be. Such are water and the minerals, although even many of these undergo some change or other. Grape-sugar is absorbed, and probably proteids too are often absorbed to some extent at least. Fat is profoundly modified during digestion, although not as the result of any digesting ferment. It may be said, however, that the great mass of food-stuff which is classed under the heads of proteids and carbohydrates is all digested by the action of ferment-like bodies. The saliva, of which about 30 ounces are secreted during the 24 hours, contains a ferment termed ptyalin, which is capable of turning starch into a soluble sugar called grape-sugar, or according to other observers, into another soluble sugar termed maltose. This can easily be demonstrated in the following manner: Take a tiny pinch of ordinary starch powder, and shake it up with a tablespoonful of water. It will not dissolve. Then boil it, when the starch will swell up, forming a thin starch paste. Dilute a few drops of tincture of iodine with several volumes of water, and add a drop of this to a small quantity of the starch paste. It will become of a rich blue colour. This is the test for starch. Now add to some of the original starch paste about one quarter of its volume of saliva from the mouth, and keep the mixture by the fire at a temperature pleasant to the hand. In a minute or so take out some of the starch in order to test it again. The iodine no longer gives a blue

colour, but produces a beautiful mahogany brown. This shows that the starch has disappeared, the brown colour being the reaction given by erythro-dextrine into which the starch has been converted. After a little time another portion tested in a similar way gives no reaction whatever, the erythro-dextrine having in its turn disappeared. The starch is now converted into sugar, mixed with a little unconverted dextrine. This being an achroo-dextrine, uncoloured like the erythro-dextrine by tincture of iodine,

The ptyalin may be extracted from the saliva or from the salivary glands themselves. It does not appear to be much exhausted during its activity, and has the general characters already discussed of unorganised ferments. The saliva is alkaline, and the starchy food is no doubt partly converted into sugar during its sojourn in the mouth and gullet by its action. When the food has reached the stomach and the acid gastric juice has mixed with it, the saliva is unable to act, and is probably killed. Any undigested starch is subsequently converted into sugar when the food reaches the small intestine by the pancreatic juice.

When the food reaches the stomach it causes a reflex secretion of gastric juice. This is but slowly produced when insipid heavy food, such as coagulated white of egg, boiled meat, sago, &c., is eaten, but flows readily when soups, broths, and fluids containing salts and extractions in abundance are taken. Thus we have a scientific reason for commencing a dinner with soup, preserving the *pièce de résistance* until the stomach has secreted gastric juice for its digestion. The gastric juice, several pounds of which are secreted daily, is acid in reaction containing free hydrochloric acid. In addition lactic and butyric acids are formed during the progress of digestion. The ferment peculiar to the stomach is termed pepsine, and it requires, unlike the ptyalin of the saliva, an acid medium for its action. Pepsine and hydrochloric acid convert proteids into substances termed peptones. The latter bodies are soluble in water, and are not coagulated by boiling like many of the proteids. In addition they pass readily through an animal membrane, and are therefore easily absorbed. The proteid does not pass directly into the peptone, but like the starch is changed into at least one intermediate body. In the first case the proteid becomes converted by the hydrochloric acid into what is called syntonin, or acid protein, and it is this syntonin which alone the pepsine has power to change into peptone. The syntonin becomes a propeptone which is intermediate in its properties between a proteid and peptone itself. It is very probable that the whole change from proteid to peptone consists in some simple change in the molecular character of the proteid, together with the addition of water. A peptone may be termed therefore a hydrated proteid, and the pepsine a hydrolytic ferment. Within the stomach, and capable of being readily extracted from the stomach of a calf, is a ferment called the milk coagulating ferment (rennet). This causes milk to coagulate, and form a clot or curd. It subsequently contracts and squeezes out some fluid termed the whey. It is difficult to assign any use to this ferment, for the acid of the gastric juice would cause of itself the milk to curdle. Still more difficult is it to explain the existence of a similar ferment in the pancreatic juice, for we cannot suppose that any milk can even pass through the stomach to be subjected to its action. The milk indeed often forms dense clots which cannot afterwards be digested, and which cause considerable gastric irritation. Milk when drunk is

frequently found to disagree with some stomachs; but even in such cases it may often be 'sipped' with impunity. In this case the formation of large clots is prevented. Lime-water causes the milk to coagulate in small soft clots.

The products of digestion, peptone and sugar, together with water and many soluble salts, are absorbed into the blood-vessels which ramify in the gastric mucous membrane. When gastric digestion is over, the undigested food (chyme) passes through the relaxed pyloric sphincter into the small intestine. The chyme consists of some proteid and starchy matter, together with fat and oil and indigestible substances such as vegetable fibre, pure wax, cartilage, &c. mixed with gastric juice. Intestinal digestion is an alkaline one, and all the digestive juices of this part of the digestive system are alkaline in their reaction. They soon counteract the acidity of the chyme, which now becomes alkaline. The proteids which remained undigested by the stomach are now acted upon by a ferment called trypsin found in the juice of the pancreas. This converts the proteids into peptones through an intermediate propeptone. The pancreatic juice contains other ferments which operate during digestion, notably a hydrolytic ferment, similar in its action to ptyalin, whereby the remaining starch is converted into sugar. The juice itself is thick and viscous. It is strongly alkaline and secreted in rather small quantity. It is said to possess a ferment capable of splitting oil and fat into glycerine and fatty acid, which it does by adding water to the fat, which is then decomposed. The fatty acid unites with the free alkali present, and a soap is formed which is subsequently absorbed. The alkaline contents of the alimentary canal also emulsify fat—i.e. they cause it to become very freely divided, forming a milky fluid. The minute microscopic globules which result pass readily through the walls of the alimentary canal into the lymphatics (lacteals). The emulsification of an oil can readily be shown by adding about half its volume of carbonate of soda (3 per cent.) solution to cod-liver oil. The latter becomes at once very similar to milk in its appearance.

The intestinal juice, the secretion of Lieberkühn's follicles, is strongly alkaline. It assists in the digestion of starch and of proteid matter. In addition an important ferment called 'invertin,' is found. This has the power of changing cane into grape-sugar and an allied substance, levulose. Both these bodies have the same formula, but differ from one another in their action on polarised light,

The importance of this ferment will be appreciated when we consider how large a quantity of food is taken in the form of cane-sugar, and that cane-sugar introduced into the blood is not of any use to the body, and is eliminated at once by the kidneys. The bile may be looked upon both as an excretion from the body and as a digestive juice. The colouring of the faeces and urine is due in part to a pigment hydrobilirubin (urobilin), which is an altered bile pigment. If bile is excreted rapidly, the faeces are dark in colour, and they may be white owing to deficient excretions. Many substances such as mucin, cholesterin, &c. found in the bile are excreted to form part of the faeces. On the other hand many bile constituents, such as the bile salts, are reabsorbed and used again in the economy. Bile has an important action in digestion, as may be shown by making biliary fistula in dogs, whereby the bile leaves the body at once through an aperture in the abdomen. In this case the

animal loses flesh; the fat which it takes with its food passes unabsorbed through its digestive system, and its excretions are offensive. The bile seems then to assist in fat absorption, and to have some antiseptic action whereby putrefaction is prevented or lessened within the digestive system. Bile assists in the absorption of fat not only by assisting in its emulsification, but also by helping in some way or other the epithelial cells, covering the villi to take up the minute fatty particles. In addition it is supposed to stimulate minute muscular fibres within the villi, which by their contraction pump the absorbed fat on into the larger lymphatics.

Within the small intestines most of the food undigested by the stomach is rendered fit for absorption. This takes place through the tissue of the mucous membrane; much of the sugar and peptones find their way into capillary blood-vessels. Absorbed products, and notably fat globules, pass into the lacteals, and thence into the blood, circulating through the veins at the root of the neck. The contents of the lacteals during absorption are called *chyle*. The contents of the small intestine pass into the large intestine, where digestion occurs to a very slight extent. Absorption is, however, more rapid, and the contents become far more solid as they pass towards the rectum, due to the deprivation of water and soluble substances. The absorptive power of the large intestine is important to remember; for injections per rectum of liquid food, especially if it has already been artificially digested, may frequently sustain life for long periods.

Artificial Digestion.—The digestive juices are occasionally defective in amount or in quality, and in this case they may be supplied artificially. All the digestive ferments may be separated by very simple processes from the glands which secrete them, and many may readily be obtained in the market. Pepsine and hydrochloric acid, taken with or before a meal, are often of great service, the most reliable preparations of pepsine being the ordinary *pepsina porci*. Food may be digested *outside the body* before its administration. Beef-tea and milk-gruel may be prepared in the following way: To bring the food to the proper temperature, boil half of it, mix it with the other half, and keep warm near the fire. To this add a preparation of the pancreatic ferments in the proportion given in the directions which invariably accompany the bottle containing the substance. The food should now be kept warm for an hour or so, and then boiled in order to prevent any further action of the ferment. It may be taken by the mouth or administered as an enema. Preparations of the pancreas are alone to be used in peptonising food outside the body, as pepsine preparations produce a bitter and unpleasant taste. Pancreatic preparations on the other hand are useless when taken with the food, as they are destroyed within the stomach.

See many separate articles throughout this work, such as those on BLOOD, CHYLE, LYMPH, BILE, SALIVA, PEP-SINE, ABDOMEN, GLANDS, DIET, FOOD, COOKERY, ALCOHOL, INDIGESTION, &c.; and the physiological hand-books of Huxley, Foster, and Landois.

Digging. See SPADE-HUSBANDRY.

Digit (Lat. *digitus*, 'a finger'), a term applied to the ten symbols of number, 0, 1, 2, &c. to 9; thus, 305 is said to be a number of three digits. Numbers were originally indicated by the fingers, and hence the name. Astronomers use digit to signify a twelfth-part of the diameter of the sun or moon, and speak of an eclipse of seven digits, meaning that seven-twelfths of the diameter is covered.

Digitālis, a genus of Scrophulariaceæ, natives chiefly of the south of Europe and temperate parts of Asia. One only, the Common Foxglove (q.v.), (*D. purpurea*), is a native of Britain. Other species have been introduced, notably *D. lutea* and *grandiflora*, with yellow flowers. The botanical name *Digitālis* (late Lat. *digitale*, 'the finger of a glove') refers, like the popular English name, to the form of the flowers.

The leaves of the *Digitālis purpurea*, collected before the expansion of the flowers and dried, are largely used in medicine, either in the form of powder, or as tincture or infusion. Digitalin granules, containing minute quantities of a mixture of the active principles, are also employed. The leaves owe their activity to the presence of certain bodies, which have been named digitalin, digitalein, digitoxin, and digitonin, the three first mentioned having the characteristic digitalis action, while the fourth is entirely different, and closely resembles saponin in its effects. The leaves and their preparations have a bitter taste. When given in large doses by the mouth, they produce violent vomiting and purging; this may prevent their absorption into the blood, but if absorbed, they may cause death by paralyzing the heart's action. When the leaves are administered in medicinal doses, a peculiar action is exerted on the muscular substance of the heart and blood-vessels, causing the former to beat more slowly, regularly, and powerfully, and contracting the latter. By this combined action the blood-pressure is raised, and if dropsy be present, a diuretic action is exerted. *Digitālis* is also used in many organic forms of heart-disease, in nervous and functional irregularity of the heart's action, in cardiac weakness from long-continued disease, in œdema of the lungs, internal hemorrhages, and other conditions. When taken for a long time it may cause nausea and other digestive disturbances, and in a very few cases sudden and serious symptoms of poisoning come on. This constitutes the so called *cumulative* action of digitalis. In therapeutic doses digitalis should slow the pulse; if too large doses be given, the pulse becomes rapid and irregular.

Digitaria. See MILLET.

Digitigrada. See CARNIVORA.

Digne, a cathedral city in the French department of Basses-Alpes, on the Bléonne, 70 miles NE. of Marseilles. Pop. 5414.

Dihong. See BRAHMAPUTRA.

Dijon, chief town in the French department of Côte-d'Or, formerly capital of the old duchy of Burgundy, lies, spread out on a fertile plain at the foot of Mont Afrique (1916 feet), at the junction of the Ouche and Suzon, and on the Canal de Bourgogne, 196 miles SE. of Paris by rail. Its importance as a railway centre has rendered it of consequence in the inner line of French defences towards the east, and strong forts now crown the neighbouring hills. The environs are exceedingly beautiful, and the town is well and regularly built; the streets are broad, the open squares numerous, and the old walls have been turned into tasteful boulevards. Of the mediæval defences, the Gothic castle built by Louis XI. still remains, employed as a gendarmic barracks; formerly it was a state-prison, in which, among others, Mirabeau, Toussaint L'Ouverture, and General Mack were confined. Among the public buildings, which are numerous and imposing, the chief are the cathedral, a massive Gothic structure, dating from the 13th century, with a wooden spire (1742), 301 feet high; the churches of Notre Dame (1252-1334), St Michel (1529), and others; a handsome theatre; the palais de justice; and the former palace of the Dukes of Burgundy, which, commenced in 1366, is now used

as the town-hall, and contains a rich museum, besides a library of 80,000 volumes and 900 manuscripts. Dijon is also the seat of an institute with three faculties—law, science, and letters—and possesses, in addition, a theological seminary, a botanic garden, and an academy of art. The manufactures include beer, brandy, woollen cloth, blankets, mustard, candles, and pottery, and there is a noteworthy trade in flowers and agricultural produce; but Dijon's chief commercial importance is as the centre of the Upper Burgundy wine trade. Pop. (1872) 40,116; (1886) 56,119. The *Dibia* of the Romans, Dijon in the 5th century passed from the Burgundians to the Franks, in the 9th was ruled by counts of its own, under the suzerainty of the bishops of Langres, but in 1007 was united to the duchy of Burgundy, of which it became the capital. On the death of Charles the Bold it came with Burgundy into the possession of France in 1477. In October 1870, after a sharp engagement before the city, Dijon capitulated to a German force. There was again severe fighting here in January 1871. Charles the Bold, Crébillon, Bossuet, and Rameau were natives, and close by is the birth-place of St Bernard, of whom there is a statue by Joutfroy (1847).

Dike. See DYKE.

Dilapidation, in English law, is where an incumbent suffers his parsonage-house or outhouses to fall down, or be in decay, for want of necessary reparation; or pulls down or destroys any of the outhouses or buildings belonging to his living; or destroys woods, trees, &c.; for it is said to extend to committing or suffering any wilful waste on the inheritance of the church. Dilapidation is a species of the legal injury known as Waste (q.v.). A rector or vicar is bound to keep his residence and the chancel of the church in repair, but not to supply or maintain anything in the way of ornament, as painting, white-washing, or papering. An ecclesiastical person suffering the church-property to get out of repair is subject to an action for dilapidation at the instance of his successor; and the money so recovered must be applied to the repairs. By 5 and 6 Vict. chap. 108, being an act to empower ecclesiastical corporations to grant long leases, it is provided that the incumbent shall not be liable for dilapidation occurring during such leases. By 34 and 35 Vict. chap. 43, amended by 35 and 36 Vict. chap. 96, a surveyor of dilapidations is appointed in each diocese. Such surveyor, when so ordered by the bishop, may inspect and report on the buildings of a benefice which is not vacant. But the bishop can issue such orders only on receipt of a complaint from the archdeacon, the rural dean, or the patron of the benefice, that the buildings of the benefice are dilapidated; and must give a month's previous notice to the incumbent, who is entitled to state written objections to the report within a month, whereupon the bishop may either call in another surveyor to report on the issues of facts, or take counsel's opinion on the issues of law, the incumbent paying the cost of such proceedings, and being obliged to comply with the bishop's final decision. The incumbent must execute the works specified in the report, as settled by the bishop, in the manner and within the time therein prescribed, or such longer time as the bishop may appoint in writing. Or he may, with consent of the bishop and the patron, and the surveyor's approval, substitute other works for them. The act also applies to cases of dilapidations in vacant benefices. The sum for repairs named in the bishop's order in those cases is a debt due from the late incumbent, his executors and administrators, to the new incumbent, and is recoverable at law or in equity. For the corresponding Scottish law, see HERITOR, MANSE.

Dilatory Pleas. See PLEA.

Dilemma. A true dilemma is defined by Whately as 'a conditional syllogism with two or more antecedents in the major, and a disjunctive minor.' The following dilemma, of the kind called destructive, will perhaps convey a clearer notion than any definition. 'If this man were wise, he would not speak irreverently of Scripture in jest; and if he were good, he would not do so in earnest; but he does it, either in jest or earnest; therefore, he is either not wise, or not good.' There being two conclusions, one or other of which your opponent must admit, he is in a manner caught between them; hence we speak of the *horns* of a dilemma.

Dilettante (pl. *dilettanti*, Ital.), in its original sense, is synonymous with an *amateur*, or lover of the fine arts. It is often used as a term of reproach, to signify an amateur whose taste lies in the direction of what is trivial and vulgar, or of a critic or connoisseur whose knowledge is mere affectation and pretence. It is sometimes assumed, in a spirit of self-depreciation, by those who are unwilling that their critical acquirements, or artistic productions, should be judged by the rules which would be applied to those of persons who had made a professional study of art. It was in this sense that it was assumed by the Dilettanti Society, a body of noblemen and gentlemen by whose exertions the study of antique art in England has been largely promoted. The society was founded in 1734, and thirty years later it sent out an expedition to make drawings of the most remarkable artistic monuments of antiquity, under Chandler, the editor of the *Marmora Ozoniensia*; Revett, joint-author with Stuart of a great work, *Athenian Antiquities*; and Pars, a talented young artist. They returned in 1766; and four splendid folios on the *Antiquities of Ionia* have since appeared at long intervals (1769, 1797, 1840, 1881). Other publications have been *Specimens of Ancient Sculpture* (2 vols. 1809-35), *Bronzes of Siris* (1836), and *Athenian Architecture* (1851).

Diligence, in the Law of Scotland, is a term used in various significations. (1) It means the care incumbent on the parties to a contract with regard to the preservation of the subject matter. In this sense the term is also used in English law, which recognises three degrees of diligence—(a) common, such as men in general exert in managing their own affairs; (b) high, such as great prudence demands; and (c) low, such as persons of less than common prudence take in connection with their own affairs. (2) The warrants issued by courts for enforcing the attendance of witnesses and the production of writings. (3) The process of law by which person, lands, or effects are attached either on Execution (q.v.) or in security for debt. In the second of these senses, it corresponds to the English *subpoena*; and in the third, generally to execution.

Diligence, the name given in French-speaking countries to a public conveyance of the nature of a stagecoach.

Dilke, CHARLES WENTWORTH, an English critic and journalist, was born December 8, 1789, graduated at Cambridge, and served for twenty years in the navy pay-office. In 1830 he became proprietor of the *Athenæum*, and from that year until 1846 he filled also its editor's chair. He established the *Daily News* in 1846, and edited it for three years. He died at Alice Holt, Hants, August 10, 1864. A collection of his articles contributed to the *Athenæum* and *Notes and Queries* between 1848 and 1863 appeared in 1875 as *The Papers of a Critic: with biographical sketch by his grandson, Sir Charles Wentworth Dilke, Bart.*

M.P. (2 vols.); the first volume treating Pope, Lady Mary Wortley Montagu, and Swift; the second, Junius, Wilkes, the Grenville Papers, and Burke. He is known also by his *Old English Plays* (6 vols. 1814).—SIR CHARLES WENTWORTH DILKE, only son of the preceding, was born in London, February 18, 1810, and educated at Westminster School, and Trinity Hall, Cambridge. He studied law, graduating as LL.B. in 1834, but did not enter upon the practice of his profession. One of the most active originators, as well as member of the executive committee, of the Great Exhibition of 1851, he was offered a knighthood by the Queen and a large pecuniary reward by the royal commission, but both offers he declined. In 1853 he was sent as a commissioner to the New York Industrial Exhibition, and in 1862 he was one of the five royal commissioners for the second exhibition, in the January of which year he accepted a baronetcy. In 1865 he was returned to parliament for Wallingford, and in 1869 he was sent to Russia as the representative of England, to the horticultural exhibition held at St Petersburg. Here he died suddenly, 10th May of the same year.—SIR CHARLES WENTWORTH DILKE, son of the preceding, was born at Chelsea, September 4, 1843. He studied at Trinity Hall, Cambridge, where he graduated in 1866, being soon after called to the bar. His travels in Canada and the United States, Australia and New Zealand, he described in his *Greater Britain: a Record of Travel in English-speaking Countries during 1866-67* (2 vols. 1868). He was returned to parliament for Chelsea in 1868. He is a doctrinaire Radical in politics, and was once at least an avowed Republican, yet he held office as Under-secretary for Foreign Affairs, and afterwards President of the Local Government Board under Mr Gladstone. In 1885 he married the widow of Mark Pattison, herself the author of *Claud Lorrain, sa Vie et ses Œuvres* (Paris, 1884), and *The Shrine of Death* (1886), a collection of stories. About the same time his name was much before the public in connection with a divorce case, and this led to his defeat at the Chelsea election in 1886, and subsequent compulsory retirement from public life. He still continued, however, to influence public opinion indirectly through the press. His *Position of European Politics* (1887) was a collection of striking essays that had appeared anonymously in the *Fortnightly Review*.

Dill (*Anethum*), a genus of Umbelliferae. The Common Dill (*A. graveolens*) is an annual or biennial plant, which grows wild in cornfields in the East and in the countries around the Mediterranean, but is quite hardy in Britain. It has from a very early period been in general cultivation as an aromatic, stimulant, and carminative, being used in cookery like anise, and in medicine as dill water, &c. *A. Sowa* is similarly cultivated, and used in Bengal, &c.

Dilleniaceæ, a tropical and subtropical order of thalamifloral dicotyledons, allied to Magnoliaceæ in habit as well as structure, and often of no less beautiful foliage and flowers. There are about two hundred species, generally astringent, and hence frequently useful in medicine and tanning; many yield excellent timber, and some also fruit, that of *Dillenia speciosa* being especially eaten in India.

Dillingen, a town of Bavaria, on the Danube, 51 miles WSW. of Ingolstadt by rail, with two monasteries, a royal high school, a seminary, and a girls' deaf-and-dumb institution. In the old castle the bishops of Augsburg formerly resided, and here they founded a university (1554-1804), which from 1564 was an active Jesuit centre. Pop. 5860.

Dillmann, CHRISTIAN FRIEDRICH AUGUST, a great Orientalist, born 25th April 1823, at Illingen, in Württemberg. Already as a student at Tübingen his studies under Ewald's influence had been turned to orientalia, and in 1846-48 he visited the libraries at Paris, London, and Oxford, cataloguing the Ethiopic MSS. at the last two, and returning to Tübingen to join its teaching staff. In 1854 he accepted a call to Kiel, where he became professor of Oriental Languages in 1860, but was transferred in 1864 to the chair of Old Testament Exegesis at Giessen, which in 1869 he resigned to become Hengstenberg's successor at Berlin. Dillmann is beyond question the first authority in Europe on the Ethiopic languages. The best books for the student in this obscure department of learning are his *Grammatik der Aethiopischen Sprache* (1857), *Lexicon Lingue Aethiopice* (1865), and his *Chrestomathia Aethiopica* (1866). Other works are his German translations of the Book of Enoch (1853), of the Book of Jubilees or the 'Little Genesis' (1849-51), and the Book of Adam (1853) in Ewald's *Jahrbücher*, as well as editions in the original of the first two; and an edition of the ancient Ethiopic translation of the Old Testament, *Biblia Veteris Testamenti Aethiopica* (2 vols. 1853-72). His contributions to pure theology are *Ueber den Ursprung der Alt-testamentlichen Religion* (1865), *Ueber die Propheten des alten Bundes* (1868), and fresh editions for the 'Kurzgefasstes Exegetisches Handbuch' of Hirzel's commentary on Job (1869), as well as of Knobel's commentaries on Exodus and Leviticus (1880), and on Genesis (1882). Dillmann became in 1877 a member of the Berlin Royal Academy of Sciences, and has contributed many papers to its issues. He was president of the fifth International Congress of Orientalists, and edited its *Abhandlungen* (3 vols. 1881-82). Other works (1879-84) deal with the history of the Ethiopic kingdom of Axum (q.v.).

Dillon, JOHN, the son of John Blake Dillon (1816-66), who was a prominent member of the Young Ireland party, and member for County Tipperary in 1865-66. Born in New York in 1851, he was educated at the Catholic University of Dublin, after which he became a doctor. He early identified himself with the Parnellite movement, and in 1880 was returned for County Tipperary. In the House of Commons Dillon soon became prominent for the violence of his language, while speeches delivered by him in Ireland led to his imprisonment in 1881, 1881-82, and 1888. From 1883 to 1885 he was absent from political life on account of ill-health; but in the latter year he reappeared, and was elected for East Mayo. He was one of the most prominent promoters of the 'Plan of Campaign.'

Dilman, a town of Northern Persia, in the province of Azerbaijan, 75 miles W. of Tabriz. Pop. 6000.

Diluents (Lat. *diluo*, 'I dilute'), medicines whose purpose is to dilute the blood, and increase the quantity of the excretions generally, especially the urine. The simplest and best of diluents is water; but all watery fluids, such as lemonade, soda-water, beer, infusions or ptisans, tea, milk, &c., may be regarded as coming under this designation. See DEMULCENTS.

Diluvium, a term formerly given by geologists to those strata which they believed to have been formed by the Deluge, and more particularly to the boulder clay. The altered opinions as to the origin of these beds have caused the word to fall into disuse in Britain. It is still used on the Continent, however, not in its original sense, but simply as a general term for the glacial and fluvio-glacial accumulations of the Pleistocene system. When

the adjective—diluvial—is employed by modern writers, it is to characterise those accumulations of gravel or angular stones which have been produced by sudden or extraordinary currents of water.

Dime, a silver coin, the tenth part of a United States dollar (see DOLLAR), and equal to about fivepence English.

Dimension. In Geometry, a point, since it has merely position, is said to have no, or to be of zero, dimensions; a line, straight or curved, is of one dimension—viz. length; a plane surface has two—length and breadth; while a solid is said to be of three dimensions—length, breadth, and thickness. Thus it will be seen that by the term dimension is meant a direction in which extension may be reckoned or measured. The three last-named dimensions are found sufficient to determine all known forms of extension. Hence space is tri-dimensional. The possibility of space of higher dimensions existing has been much discussed. Since points, lines, and surfaces in general generate by their motion lines, surfaces, and solids respectively, so it is held that some analogous generation of a fourth dimensional figure by one of three dimensions is conceivable. The subject, although interesting, is wholly speculative.—In Algebra, the term dimension is employed in much the same sense as *degree*, to express the sum of the indices of those letters with reference to which the term containing them is considered—e.g. xy , x^2 , are both of two dimensions, or of second degree; x^2y , x^3 , are of three dimensions, or third degree, &c.

Dimidiation, in Heraldry, a mode of marshalling arms, adopted chiefly before quartering and impaling according to the modern practice came into use, and subsequently retained to some extent in continental though not in English heraldry. It consists in cutting two coats of arms in half by a vertical line, and uniting the dexter half of the one to the sinister half of the other. Coats of husband and wife were often so marshalled in England in the 13th and 14th centuries.

Dimity, a stout, figured cotton-fabric, used chiefly for bed-hangings and window-curtains. The figure or stripe is distinctly raised. Originally dimity was commonly white or of a single colour; but variegated dimities are now largely made; one band or stripe of the cloth having a woven pattern in white alternating with a plain band—i.e. the fabric is all white as it comes from the loom. A pattern is afterwards printed in colours on the plain band.

Dimorphism (Gr. *dis*, 'twice'; *morphē*, 'shape or form'), a technical term applied in Biology to cases where an organism appears in two different forms. Thus in a colony of hydroids there may be 'dimorphic persons'—respectively nutritive and reproductive, and yet fundamentally the same in structure and origin. So too when the two sexes are markedly different, the term sexual dimorphism may be used. Or the organisms may be different at certain seasons and in certain conditions, as in summer and winter Butterflies (q.v.), or in the two kinds of common Primrose (q.v.) and cowslip. Sometimes three different forms of butterfly are known in the same species, and to such cases the term *trimorphism* is conveniently applied. The same is true of the common flower *Lythrum salicaria*. In hydroid and medusoid colonies (e.g. *Hydractinia* and *Siphonophora*) the development of multiple forms resulting from 'Division of Labour' (q.v.) is described as *polymorphism*. The same term is obviously applicable to the different forms exhibited by some social Ants (q.v.). The same set of terms may also be employed in reference to different forms of the same mineral, &c. See also FLOWERS, FERTILISATION.

An inorganic substance is in a somewhat analogous manner said to be dimorphous when it is capable of crystallising in two different forms or systems (see CRYSTALLOGRAPHY). A large number of substances have this property, of which sulphur, carbon, carbonate of lime, and iodide of mercury are the best examples. Thus carbon, as the diamond, crystallises in the regular system, as octahedra, while as graphite, or Black Lead (q.v.), it forms hexagonal crystals belonging to the rhombohedral system. In some cases there is a great tendency for the one form of crystal to change spontaneously into the other form. The red iodide of mercury is a striking example of this. When heated, this substance is volatilised, and may be condensed on a glass plate as a yellow crystalline crust, consisting of rhombic plates. When this is rubbed, or even scratched, an immediate change takes place, the rhombic plates becoming broken up into octahedra, while the colour at the same time alters from yellow to a brilliant scarlet. So also when sulphur is crystallised from its solution in bisulphide of carbon, it yields transparent amber-coloured octahedra; but when melted sulphur is cooled, prismatic crystals are the result. In the course of a few days the prisms become opaque, owing to their being broken up into small octahedra, while conversely the octahedra, when heated to 230° (110° C.), are changed into smaller prismatic crystals. Those substances, such as sulphate and selenate of nickel, which crystallise in three systems, are said to be *trimorphous*.

Dimsdale, THOMAS (1712-1800), an English physician who wrote several works on inoculation, was famous as an inoculator (making journeys in 1708 and 1784 to Russia to inoculate the Empress Catharine and other magnates), and sat for Hertford in two parliaments.

Dinājpur, capital of a district in the Rajshahi division (Kuch Behar) of Bengal, stands 221 miles N. of Calcutta by rail, on the Purnabhaha River, which, through the Mahananda, enters the Lower Ganges. Pop. 12,560.—The district has an area of 4118 sq. m., and a pop. (1881) of 1,514,346, almost entirely rural, and mainly of aboriginal descent. The Mussulmans slightly outnumber the Hindus.

Dinan, a very old town in the French department of Côtes-du-Nord, on the Rance, 30 miles NW. of Rennes, and 14 S. of St. Malo. The situation of Dinan, on the summit of a steep hill of granite, and with the Rance flowing through a valley 250 feet below, is romantic in a high degree. The valley is crossed by a fine granite bridge of ten arches. The town is still partly surrounded by its old ivy-covered walls. The old castle of the Dukes of Brittany is now in part used as a prison. In the older district the streets are crooked, narrow, and steep; in some parts, the overhanging houses, and arcades resting on carved granite pillars, present many picturesque architectural features. The church of St. Sauveur, a fine Romanesque church, contains the heart of the famous French warrior Bertrand du Guesclin, who here had a famous encounter with an English knight. The terraces around the town afford very charming views. Many English reside here. Pop. 9704. Four miles off lies the village of Corseult, on an old Roman site, where many antiquities have been found.

Dinant, a town of Belgium, occupying a narrow site between the Meuse and a limestone hill, 17 miles S. of Namur by rail, and consisting mainly of one narrow street. On the cliff above stands the citadel (1530), and the Gothic church dates from the 13th century. There are manufactures of cotton, paper, leather, iron, &c., with black marble quarries; and the gingerbread of Dinant, com-

posed of rye-flour and honey, has an extensive sale. The place was formerly noted for its copper wares, familiarly known as *Dinanderie*. Pop. 6773. Dinant, which dates from the 6th century, has suffered greatly from frequent sieges. The present fortifications date from 1815.

Dinapore (*Dināpur*), military headquarters of the district of Patna in Bengal, on the Ganges, 12 miles W. of Patna city by a road lined with houses throughout. It is divided into two parts, the Cantonments and the Nizamat, or city proper. Pop. (1881) 37,893, of whom 23,740 resided within the Nizamat. In the mutiny of 1857 the three sepoy regiments stationed here rose in July, and escaped into Shahabad district, where they attacked Arrah (q.v.).

Dinaric Alps, the name applied to the mountains connecting the Julian Alps with the Balkan system. The main range stretches from north-west to south-east, separating Dalmatia from Bosnia and Herzegovina, as far as the mouth of the Narenta; and a minor chain extends through the Dalmatian coast country. The mountains are principally calcareous; the highest summits are Orjen (6225) and Dinara (5940), and the mean height is 2300 feet.

Dindigal, a town in the presidency of Madras, 40 miles NNW. of Madura by rail, with an old fort, still in good preservation, commanding the approaches to Coimbatore from the south. It has a trade in hides, tobacco, coffee, and cardamoms. Pop. (1881) 14,182, mostly Hindus.

Dindorf, WILHELM, a famous Hellenist, born 2d January 1802 at Leipzig, where his father Gottlieb Immanuel Dindorf (died 1812) was professor of Oriental Languages. In 1817 he began his studies in philology at Leipzig, under Gottfr. Hermann and Chr. Daniel Beck, declined a call to Berlin in 1827, and next year accepted an extraordinary professorship at Leipzig, which he resigned in 1833 to devote himself entirely to his literary activity. Here he died, 1st August 1883. Dindorf's long life gave many contributions of the first value to Greek scholarship, especially in the region of dramatic poetry. Among his works were the preparation of vols. 7-13 of the great Invernizzi-Beck edition of Aristophanes (1820-34), editions of Aristophanes, with notes and scholia (1835-39), of Æschylus (1841-51), Euripides (1834-63), Sophocles, with notes (1832-36), and a second vol. of the series of scholia to Sophocles, edited by Elmsley (1852), also an edition with annotations and scholia of Demosthenes (1846-51), all printed at Oxford. Other works are those on the metres of Æschylus, Sophocles, Euripides, and Aristophanes (1842); the lexicons to Sophocles (1871) and Æschylus (1873-76); his edition of the text of Homer (1855-56), and of the scholia to the *Odyssey* (1855) and the *Iliad* (1875-77). With Hase and his brother Ludwig (1805-71) he edited the *Thesaurus Græcæ Linguae* of Stephanus (1832-65).

Dingelstedt, FRANZ VON, German poet, born near Marburg in 1814, was royal librarian at Würtemberg in 1843-50, intendant of the court theatres at Munich, Weimar, and Vienna in 1850-71, and afterwards director of the Burg Theatre in Vienna. He was ennobled by the Austrian emperor, and died 15th May 1881. Besides several volumes of poems, displaying great versatility and considerable power, he published a series of novels, one fine tragedy (*Das Haus der Barneveldt*), essays, and translations and studies of Shakespeare. His collected works fill 12 vols. (1877).

Dingle, a seaport on the north side of Dingle Bay, in County Kerry, Ireland, 27 miles SW. of Tralee railway station, and 30 WNW. of Kil-

larney. The chief exports are corn and butter. The harbour is landlocked. Pop. 1833.

Dingo (*Canis dingo*), a variety of dog found in Australia, both in a wild and a domesticated state. As marsupials are believed to be the only indigenous Australian mammals, it is probable that this dog, which is found in a semi-fossil state in some of the caves, was introduced by or with the earliest human

Dingo, or Australian Dog (*Canis dingo*).

inhabitants. The dingo has an elongated flat head, which is carried high; the ears are short and erect, and are kept in that position when the animal runs; the fur is soft and predominantly tawny; the tail is bushy and kept low down. It is a very muscular, fierce animal, tenable if taken young. In the wild state it seldom barks. The wild forms, joined doubtless by recent runaways from domestication, used to work very great havoc among the sheep, but vigorous endeavours have vastly reduced their numbers and minimised their ravages. See Dog.

Dingwall (Scand., 'court hill'; see THING), the county town of Ross-shire, near the head of the Cromarty Firth, and at the entrance to the valley of Strathpeffer, 13½ miles NW. of Inverness (by rail 18½). It has the county buildings (1845), a public park, a small harbour, and an obelisk, 57 feet high, which marks the grave of Sir George Mackenzie, first Earl of Cromarty. A royal burgh since 1226, it unites with Wick and four other towns to return one member to parliament. Pop. (1861) 2099; (1881) 1921.

Dinkelsbühl, an ancient walled town of Bavaria, on the Wörnitz, 19 miles NNW. of Nördlingen by rail, with manufactures of cordage, hosiery, straw-hats, pencils, brushes, &c. It was formerly a free city of the empire, and suffered much during the Thirty Years' War. Pop. (1880) 5186; (1885) 4457.

Dinocerata (Gr. *deinos*, 'terrible,' and *keras*, 'horn'), an extinct order of mammals, approaching the elephant in size and movements, remains of which have been found extensively in the Eocene lacustrine sediments of southern Wyoming. The dinocerata include three genera—*Uintatherium* (most primitive type), *Dinoceras* (intermediate form), and *Tinoceras* (youngest and most specialised). About thirty more or less distinct forms have been recognised. The feet were plantigrade, the fore-foot being larger than the hind-foot, and having five digits; the limbs were massive and heavy, but shorter than in the elephant; the skull was long and narrow, supporting on top three separate transverse pairs of high osseous protuberances or horn-cores, while the canine teeth were enormously developed in the male, and formed short, trenchant, decurved tusks; the nasal bones were elongated so as to form nearly half the length of the skull, though, as the neck was long enough

to allow the head to reach the ground, there was probably no proboscis; finally, the brain was proportionately smaller than in any other known mammal, and even less than in some reptiles. See Professor O. C. Marsh's admirable monograph, published by the United States Geological Survey (1884).

Dinornis. See MOA.

Dinosauria (Gr., 'terrible lizards'), an important group of Mesozoic reptiles, known partly by their skeletons, partly by their footprints. They were gigantic forms, some of them at least 80 feet in length, and many of their characters lead on to birds. Thus in the hip-girdle the pubic bones were in many cases turned, not forwards as in other reptiles, but backwards as in birds; the legs were also in part bird-like; the fore-limbs were less developed than the legs; some of the bones apparently contained air-cavities, &c. *Atlantosaurus* (q.v.), *Stegosaurus*, *Iguanodon* (q.v.), and *Megalosaurus* (q.v.) are important types. They begin in Triassic strata, become very prominent in the Jurassic fauna, continue well represented in the Chalk, and then terminate. A large number have been found in America, and our knowledge of them is mainly due to the researches of Pope and Marsh. They were terrestrial animals, though some, such as *Iguanodon*, frequented marshy ground. Some seem to have been carnivorous, others vegetarian. The group is a large and varied one, gradually becoming more defined in its limits and characters. The relations to other fossil reptiles will be discussed under REPTILE.

Dinotherrium (Gr., 'terrible beast'), a remarkable extinct animal, the cranial bones of which are found in the Miocene formations of Germany, France, &c. The animal was provided, like the elephant and the walrus, with a pair of long tusks; but these projected from the end of the lower jaw, which is deflected downwards at a right angle to the body of the jaw. Both jaws possessed a series of præ-molars and molars, the crowns of which were traversed by strong transverse ridges. The nasal cavity was large, apparently supplying attachment for a trunk, as in the elephant. Very little is known

Dinotherrium, as restored by Kaup.

of the skeleton except the skull (one example of which is 3½ feet long); and hence the true position of the dinotherrium has not been satisfactorily determined. Cuvier and Kaup have referred it to the neighbourhood of the tapir, supposing it to have been an inhabitant of large lakes.

Dinwiddie, ROBERT, colonial governor of Virginia, was born in Scotland about 1690, and was governor of Virginia from 1752 to 1758, when he was recalled, after precipitating the French and Indian war, and by his ill-temper, avarice, and incompetence, rendering himself generally unbearable to the Americans. He died in 1770.

Dio Cassius. See DION CASSIUS.

Dio'cesan is a bishop viewed in relation to his own clergy or flock.

Diocesan Courts. See CONSISTORY and COMMISSARY.

Diocese (Fr., from Gr. *diokēsis*, 'administration'), the territory over which a bishop exercises ecclesiastical jurisdiction. The term occurs as early as the time of Demosthenes, to signify the treasury or department of finance. It is found in Cicero, both as a Greek and as a Latin word, as the special designation of districts in Asia Minor. At this time, the area denoted by this term was but a small one, for Cicero mentions that three dioceses were included in the single province of Cilicia. But in the organisation of the Roman empire introduced by Constantine the Great, the designation diocese was applied to the larger divisions, which were subdivided into provinces or eparchies. About the middle of the 5th century, the dioceses of the empire were—the East, Asia, Pontus, Thrace, Macedonia, Dacia, Illyria, Italy, Africa, Gaul, Spain, and Britain. The city of Rome, with its seven 'suburbicarian' provinces, constituted a diocese in itself, and was not included in that of Italy. The dioceses were governed collectively by four Prætorian Prefects, each of whom had several such territories under his jurisdiction, and singly by officers styled Eparchs, Counts, or Vicars. The provinces (numbering one hundred and seventeen) were under Exarchs or Rectors. The government of the Christian church, as established by Constantine, was assimilated to this division, and the term diocese and others passed over to ecclesiastical matters. At first a diocese meant an aggregate of metropolitan churches or provinces, each under the charge of an archbishop, which had previously been called a parish, into a single jurisdiction under an exarch (Balsamon, *ad Can. ix., Conc. Chalced.*); and the actual distribution in the 4th and 5th centuries was founded on, and closely corresponded to, the civil division. The four (later five) patriarchates corresponded to the four prætorian prefectures; and the diocese of the Orient contained fifteen provinces, all under the Patriarch of Antioch, till the erection of the patriarchate of Jerusalem in 450, when Palestine, Phœnicia, and Arabia were withdrawn from Antioch to constitute the new jurisdiction; Egypt, under the Patriarch of Alexandria, had six provinces; Asia, eleven; Pontus, eleven; Thrace, six; Macedonia, six; Dacia, five; Italy, seventeen, of which seven were in the diocese of Rome; Illyria, six; Africa, six; Spain, seven; Gaul, seventeen; and Britain, five. In a later stage of the church's history, the term diocese is applied to a single metropolitanate or province (Greg. Mag. *Epist.*, VII. ii. 17), and lastly it came to signify the local jurisdiction of any one bishop (a meaning already applied to it as early as the second Council of Carthage, in 390 A.D., canon v.), of whatever rank. It does not appear in England till the writings of Matthew Paris in the middle of the 13th century; Bede, for example, using only the terms *episcopatus*, *provincia*, *ecclesia*. On the other hand, it is found as the equivalent of 'parish' in canons of the councils of Agde (506 A.D.), Epaon (517), Orleans IV. (541), and also in the capitularies of Charlemagne, VII. c. 360. England and Wales are divided ecclesiastically into two provinces—viz. Canterbury and York, the former being presided over by the Primate of All England, and the latter by the Primate of England. Each of them is subdivided into dioceses, and these again into archdeaconries, rural deaneries, and parishes. See BISHOP.

Diocletian. VALERIUS DIOCLETIANUS, Roman emperor (284–305 A.D.), was born of humble parentage near Salona, in Dalmatia, in 245. He inherited from his mother, Dioclea, the name

of Diocles, which he afterwards enlarged into Diocletianus, and attached as a cognomen to Valerius, a name of the most patrician associations. He adopted a military career, and served with distinction under Probus and Aurelian, accompanied Carus on his Persian campaign, and finally, on the murder of Numerianus having been discovered at Chalcedon, he was proclaimed emperor in 284 by the army on its homeward march. The suspected assassin of Numerianus, the prefect Arrius Aper, he slew with his own hands, in order, it is alleged, to fulfil a prophecy communicated to him, while still a lad, by a Druidess of Gaul, that he should mount a throne as soon as he had slain the wild-boar (*aper*). Next year he commenced hostilities against Carinus, the joint-emperor along with the deceased Numerianus, who, although victorious in the decisive battle that ensued, was murdered by his own officers, thus leaving to Diocletian the undisputed supremacy. His first years of government were so molested by the incursions of barbarians, that, in order to repel their growing aggressiveness, he took to himself a colleague—namely, Maximianus—who, under the title of Augustus, became joint-emperor in 286. Diocletian reserved for himself the charge of the eastern empire, and gave the western to Maximian. Still the attacks of the barbarians continued as formidable as ever. The empire was menaced by the Persians in the east, by the Germans and other barbarians in the west; and in order to provide for its permanent security, Diocletian subjected it to a still further division. In 292 Constantius Chlorus and Galerius were proclaimed as Cæsars, and the distribution of the Roman empire was now fourfold: Diocletian taking the East, with Nicomedia as his seat of government; Maximian, Italy and Africa, with Milan as his residence; Constantius, Britain, Gaul, and Spain, with Trèves as his headquarters; Galerius, Illyricum and the entire valley of the Danube, with Sirmium as his imperial abode. It was upon his colleagues that most of the burden of engaging actively in hostilities fell, as Diocletian seldom took the field in person. Among the conquests, or rather re-conquests, that were made under his rule, may be enumerated that of Britain, which, after maintaining independence under Carausius and Allectus, was in 296 restored to the empire; that of the Persians, who were defeated, and compelled to capitulate in 298; and that of the Marcomanni, and others of the northern barbarians, who were driven beyond the Roman frontier. Diocletian, after twenty-one years' harassing tenure of government, desired to pass the remainder of his days in tranquillity. Accordingly, on the 1st of May 305, he abdicated the imperial throne at Nicomedia, and compelled his reluctant colleague, Maximian, to do likewise at Milan. He sought retirement in his native province of Dalmatia, and for eight years resided at Salona, devoting himself to philosophic reflection, to rural recreation, and to horticultural pursuits. Two years before his abdication, he was instigated by his colleague, Galerius, to that determined and sanguinary persecution of the Christians for which his reign is chiefly memorable. He died in 313.

Diodati, JEAN, a Calvinistic divine, was born at Geneva, 6th June 1576, became professor of Hebrew there in 1597, pastor of the reformed church in 1608, and in 1609, on the death of Beza, professor of Theology. He was a preacher at Nîmes from 1614 to 1617, and at the Synod of Dort was representative of Geneva. Diodati, whose family was originally of Lucca in Italy, tried in vain to introduce the reformed doctrine in Venice. He is remembered chiefly through his Italian translation of the Bible, issued (without imprint) at

Geneva in 1607, which was one of the best translations of the Reformation period, and is still in use. His *Annotationes in Bibliā* (1607) are also of value. He died at Geneva, 3d October 1649. See Budé, *Vie de Jean Diodati* (Geneva, 1869).—A nephew, CHARLES DIODATI (circa 1608–38), is remembered as the friend of Milton. Son of a doctor, who had settled in England, he was educated at St Paul's School, and Trinity College, Oxford, and for the last nine years of his life practised medicine near Chester and in Blackfriars.

• **Diodon.** See GLOBE-FISH.

Diodorus Siculus, a Greek historian, was born at Agrigum, in Sicily. Little is known of his life beyond what is told by himself. He lived in the times of Julius Cæsar and Augustus, travelled in Asia and Europe, and lived a long time in Rome, collecting the materials of his great work, the compilation of which occupied thirty years. This work, the *Bibliothekē Historikē*, was a history of the world, in forty books, from the creation to the Gallic wars of Julius Cæsar. It was divided by the author into three parts—the first of which, in six books, comprises all the Greek and foreign mythical history down to the Trojan war; the second, in eleven books, contains the history from the year 1184 B.C. to the death of Alexander the Great; the third, in twenty-three books, continues the narrative of events from that date to the year 60 B.C. Of this great work, the first five books are extant entire; the next five books are wholly lost; the next ten are complete; and of the remainder of the work, considerable fragments have been preserved in the *Excerpta* in Photius, and in the *Eclogæ* prepared by command of Constantine Porphyrogenitus. Had Diodorus Siculus possessed any powers either of criticism or of arrangement, his work would have been of the greatest importance; but he was in both respects so deficient, that his history has no practical value beyond what belongs to an immense mass of raw and now scarcely available material. His narrative is colourless and monotonous, and his diction, generally clear and simple, holds a sort of middle place between the pure Attic and the colloquial Greek of his time. The best editions of Diodorus Siculus are Wesseling's (Amst. 1746), L. Dindorf's (1828–31), and Bekker's (1853–54).

Diœcious (Gr. *dis*, 'twice,' and *oikos*, 'a habitation'), a term applied by Linnaeus to plants in which separate individuals exclusively produce male and female flowers respectively. Great importance was attached to this in the artificial system of classification; but diœcious species occur in all groups of plants indifferently, however commonly hermaphrodite; and similarly, hermaphrodite forms occur in groups usually diœcious. This is probably explained by regarding the complete separation of the sexes as a phase of evolution beyond hermaphroditism which tends to arise in plants as in animals, and from which reversion to hermaphroditism may also readily occur, probably in conditions favourable to vegetativeness (see SEX, REPRODUCTION). Familiar examples of diœcious plants may be seen in most species of willow, or in the pink or white *Lychnis* (*L. diurna* and *L. vespertina*), or the Common Nettle (*Urtica dioica*). Amongst cultivated plants, hemp, spinach, and the date-palm may be instanced.

Diogenes, the Cynic philosopher, was a native of Sinope, in Pontus, where he was born about 412 B.C. His father, a banker named Iesias or Ictas, was convicted of swindling, and so, the young Diogenes had to leave Sinope and go to Athens. His youth had been that of a spendthrift and a rake, but at Athens his interest was arrested by the character of Antisthenes, who, however, re-

pelled his first advances. But not even blows could restrain the enthusiastic ardour of the young disciple, and at length Antisthenes, moved with compassion, consented to admit him as a pupil. From an extravagant debauchee, Diogenes at once became an ascetic of the extremest austerity. He would roll in hot sand during the heat of summer; in winter, he would embrace a statue covered with snow. His clothing was of the coarsest, his food of the plainest. His bed was the bare ground, whether in the open street or under the porticoes. At length he found himself a permanent residence in a tub which belonged to the Metroon, or the temple of the Mother of the Gods. His eccentric life did not cost him the respect of the Athenians, who admired his contempt for comfort, and allowed him a wide latitude of comment and rebuke. Practical good was the chief aim of his philosophy; for literature and the fine arts he did not conceal his disdain. He laughed at men of letters for reading the sufferings of Ulysses, while neglecting their own; at musicians who spent in stringing their lyres the time which would have been much better employed in making their own discordant natures harmonious; at philosophers for gazing at the heavenly bodies, while sublimely incognisant of earthly ones; at orators who studied how to enforce truth, but not how to practise it. He was seized by pirates on a voyage to Ægina, and carried to Crete, where he was sold as a slave. When asked what business he understood, he answered: 'How to command men.' His purchaser was Xenias of Corinth; but the slave soon came to rule the master, acquired his freedom, was appointed tutor to the children, and spent his old age as one of the household. It was here that he had his interview with Alexander the Great. The king opened the conversation with: 'I am Alexander the Great,' to which the philosopher answered: 'And I am Diogenes the Cynic.' Alexander then asked him in what way he could serve him, to which Diogenes rejoined: 'You can stand out of the sunshine.' Alexander is said to have been so struck with the Cynic's self-possession, that he went away remarking: 'If I were not Alexander, I would be Diogenes.' The philosopher lived at Corinth till his death at the age of ninety, 323 B.C. See Hermann, *Zur Geschichte und Kritik des Diogenes* (Heilbronn, 1860).

Diogenes Laertius seems to have been born at Laerte, in Cilicia, and to have taken his surname from that town. Little is known of his history; but it is most probable that he flourished in the 2d century A.D. His name has been kept alive by his *Lives of the Philosophers*, a work in ten books, in which he divides the philosophy of the Greeks into the Ionic—beginning with Anaximander, and ending with Chrysippus and Epicurus—and the Italian, founded by Pythagoras, and ending with Epicurus. The Socratic school was a part of the Ionic philosophy; to the Italian belong the Eleatics, with Heraclitus and the Sceptics. This work contains a great mass of interesting information regarding the private lives and habits of the most eminent philosophers of antiquity. Though it is utterly worthless in respect of plan, coherence, or criticism, it yet contains so many piquant anecdotes, and so many valuable quotations from lost works, that Montaigne's wish was perhaps a justifiable one—that instead of one Laertius, we had had a dozen. The best editions of Laertius are those of Hübner (Leip. 1828–31) and Cobet (Paris, 1850).

• **Diomedea.** See ALBATROSS.

Diomede Islands, a group of three small islands (Fairway, Krusenstern, and Ratmanoff) in Behring Strait, forming, as it were, stepping-stones between Asia and America.
